DAVIES, F. H.	Electric Traction.
DE COVERLEY, ROGER	Bookbinding.
ELLISTON, R. J.	Types and Typography.
GOODCHILD, J. G.	Geology.
GOODCHILD, W., M.B., B.Ch.	Mineralogy.
GRIFFIN, H. H.	Motor Cycles and Motor Boats.
HARPHAM, W.	Lace Manufacture.
HEYLIN, H. B.	Cotton Manufacture.
HURTLEY, W. H., D.Sc.	Chemistry.
JENNINGS, A. SEYMOUR	Oils, Colours, Decoration.
LOCKYER, W. J. S., Ph.D.	Meteorology.
NEW, C. H., F.I.C.	Chemical Technology.
PARKER, J. GORDON, Ph.D.	Leather Manufacture.
PURCHON, W. S.	Architecture.
RHEAD, G. W.	Engraving and Etching.
SEAGER, J. A., A.I.E.E.	Electric Lighting and Electric Motors.
SENIOR, EDGAR	Photography.
SHAW, W. BOLTON, B.Sc.	Steam Engines.
SINDALL, R. W., F.C.S.	Paper Manufacture and Wood Pulp.
SMITH, P. CALDWELL, M.A., M.D., D.P.H.	Sanitation.
STANSBIE, J. H, B.Sc.	Metallurgy and Metallography.
SZLUMPER, A. W., M.Inst.C.E.	Railways.
TONGE, J., M.I.M.E., F.G.S.	Mining.
VAN STONE, J. H., F.L.S.	Botany.
WARNER, F.	Silk Manufacture.
WELLS, WHARTON, L.R.A.M., F.R.C.O.	Musical Terms and Musical Instruments.
WILLIAMS, ARCHIBALD	Speed Gears and Tyres.
WRIGHT, T. D.	Watches and Clocks.

PREFACE

THE object of the Dictionary is to furnish the modern signification of technical terms employed in the Arts and Sciences enumerated on p. vii, and by means of compendious articles to elucidate the principles and processes of pure and applied science.

The numerous articles on the various branches of Chemistry, Theoretical, Practical and Applied, as well as those on Mineralogy and Metallurgy, afford the latest information available, much of which is not to be found in earlier standard works of reference dealing with these subjects.

For explanation of or further details concerning the technical terms that occur in the longer articles, readers should refer to the general alphabetical arrangement.

Purchasers of the Dictionary are recommended to compare the *Corrigenda* with the definitions to which they refer and to make the actual corrections.

The Editors will be grateful to readers who kindly inform them of any errors not already corrected.

September, 1906.

„ CORRIGENDA	875

SCOPE

THE Dictionary contains Definitions of the Technical Terms most frequently employed in the several Arts and Sciences enumerated below, as well as numerous Articles, some of them of considerable length, dealing with various branches of these Arts and Sciences:

- ARCHÆOLOGY
- ARCHITECTURE
- ART
- ASSAYING
- ASTRONOMY (PURE AND APPLIED)
- BOOKBINDING
- BOTANY (ECONOMIC)
- BRICKMAKING
- BUILDING TRADES (BRICKLAYING, MASONRY, CARPENTRY, JOINERY, HOUSE-PAINTING, PAPERHANGING, PLUMBING, QUANTITY SURVEYING)
- CERAMICS
- CHEMISTRY
- CYCLE MANUFACTURE
- DYEING
- ELECTRICITY
- ENGINEERING (CIVIL, ELECTRICAL, MECHANICAL)
- ENGRAVING AND ETCHING
- GEOLOGY
- GLASS MANUFACTURE
- HERALDRY
- HYGIENE
- LAND SURVEYING
- LEATHER TANNING AND DYEING
- METALLURGY
- METEOROLOGY
- MINERALOGY
- MINING
- MOTORS AND MOTOR-CAR MANUFACTURE
- MUSIC
- OIL MANUFACTURE
- PAINT MANUFACTURE
- PAINTING
- PAPER MANUFACTURE
- PHOTOGRAPHY AND PROCESS WORK
- PHYSICS
- PRINTING
- SCULPTURE
- STEAM ENGINE CONSTRUCTION
- TEXTILE MANUFACTURES (COTTON, LACE, LINEN, SILK, WOOL, ETC.)
- WATCH AND CLOCK MAKING
- WEIGHING, MEASURING, ETC.
- WOOD PULP MANUFACTURE
- ZOOLOGY (ECONOMIC)

KEY TO THE ABBREVIATIONS USED IN CLASSIFYING THE TERMS INCLUDED IN THE DICTIONARY

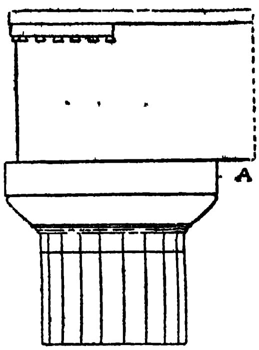
(*Archæol.*)	= Archæology
(*Architect.*)	= Architecture
(*Arm.*)	= Armour
(*Astron.*)	= Astronomy
(*Bind.*)	= Bookbinding
(*Biol.*)	= Biology
(*Build.*)	= Building
(*Carp.*)	= Carpentry
(*Chem.*)	= Chemistry
(*Chem. Tech.*)	= Chemical Technology
(*Civil Eng.*)	= Civil Engineering
(*Cost.*)	= Costume
(*Dec.*)	= Decoration
(*Elect.*)	= Electricity
(*Elect. Eng.*)	= Electrical Engineering
(*Eng.*)	= Engineering
(*Engrav.*)	= Engraving
(*Geol.*)	= Geology
(*Her.*)	= Heraldry
(*Join.*)	= Joinery
(*Math.*)	= Mathematics
(*Manufac.*)	= Manufacture
(*Mech.*)	= Mechanics
(*Met.*)	= Metallurgy
(*Meteor.*) and (*Meteorol.*)	= Meteorology
(*Min.*)	= Mineralogy
(*Paint.*)	= Painting
(*Photo.*)	= Photography
(*Phys.*)	= Physics
(*Plast.*)	= Plastering
(*Plumb.*)	= Plumbing
(*Pot.*)	= Pottery
(*Print.*)	= Printing
(*Sculp.*)	= Sculpture
(Tw.)	= Twaddell
(*Typog.*)	= Typography
(*Zool.*)	= Zoology

A TECHNOLOGICAL AND SCIENTIFIC DICTIONARY.

A (*Music*). The sixth note of the diatonic scale of C, and the first or key-note of the relative minor scale. Its Sol-Fa and Continental name is La. A is the note sounded to which all the instruments in the orchestra are tuned. On all stringed instruments it is found as an "open" string—that is, the note to which a string is tuned. One of the clarinets is in the key of A, the other two being respectively B♭ and C.

"A" Frame (*Eng.*) A triangular frame with a cross bar forming the supports of some part of a machine or other structure.

Abacus (*Architect.*) The uppermost member or feature of the capital of a column. It supports the architrave (*q.v.*) In the Doric, Tuscan, and ancient Ionic orders it is merely a flat square slab; but in the Corinthian and Composite orders it is shaped differently, and ornamented. *See* COLUMN, CORINTHIAN, COMPOSITE.



A, ABACUS (GRECIAN DORIC).

Abaissé (*Her.*) Not in its usual place in a shield, but lowered.

Abatements (*Her.*) Marks of degradation, not now used; cf.:

> Yea though I die, the scandal will survive,
> And be an eyesore in my golden coat;
> Some loathsome dash the Herald will contrive
> To cipher me.
>
> SHAKESPEARE.

Abatjour (*Architect.*) A sloping aperture made in a wall for the purpose of admitting light to basements and such other apartments.

Abattoirs. Abattoirs, or public slaughter houses, are of great importance in the regulation of our meat supply by providing a means whereby the meat can be closely examined before being sent to the market. They are under the control of the sanitary authorities, who are empowered by the Public Health Acts to make byelaws for the licensing, registering, and management thereof. It is most essential that the drainage, water supply, and ventilation be kept in efficient order, and that all waste refuse be immediately removed.

A Battuta (*Music*). With the beat.

Abatvoix. The canopy or sounding board over a pulpit or rostrum to deflect the sound of the voice.

Abb (*Weaving*). West of England term for "weft," *i.e.* the yarn or thread used in weaving for crossing and interlacing with the warp. This term is also applied to a certain quality or sort of fleece.

Abbey. A church attached to a monastery or convent: a name given to a church that once belonged to a religious community—*e.g.* Westminster Abbey.

Abbozzo (*Paint.*) The first sketch or rough draft of a picture.

Abdomen (*Zoology*). The posterior part of the trunk of an animal. It is unprotected by a bony framework on the belly or under (ventral) surface.

Abdominal Pores (*Zoology*). A pair of apertures, one on each side of the cloaca (*q.v.*) of fishes of the Shark family. These openings communicate with the body cavity.

Aberdeen Granite. *See* BUILDING STONES.

Aberration (*Light*). An apparent displacement in the position of a body, owing to the observer's motion while light is travelling from it to the observer. It was first noted in connection with the supposed "Fixed" stars.

——, **Chromatic** (*Light*). The splitting up of light into its component colours (or DISPERSION, *q.v.*) by a lens, owing to the different refractive index of each component. This gives an image with a coloured margin. Corrected by suitably combining two lenses of different glass. *See* ACHROMATISM.

——, **Spherical** (*Light*). The meeting of reflected or refracted rays in a succession of points, instead of in one single point, which results from the reflecting or refracting surface being spherical. This error is corrected by modifying the form of the surface (*e.g.* mirrors are made of parabolic, instead of circular, section).

Abezzo, Olio di (*Paint.*) An oil produced from the pine tree, used as varnish.

Abney Level. A form of reflecting level and clinometer combined.

Abococke (*Cost.*) A hat pointed in front, with the brim turned up behind, worn by royal personages during fourteenth to sixteenth centuries.

Abolla (*Cost.*) A loose cloak made of wool, especially used by the Stoic philosophers.

About Sledge (*Eng.*) The use of a double-handed or "sledge" hammer for the delivery of heavy blows by swinging it above the head.

Abrasion. Rubbing away, or grinding, of some material. The action of a grindstone and emery or glass paper may be quoted as examples.

N.B.—It will be noted that no medical or anatomical definitions are given in the DICTIONARY. For example, in the case of **Abdomen** only the zoological meaning is signified.

Abraxas (*Archæol.*) Gems on which the mystic word Abraxas was graven, used as charms by the Gnostics about the second century.

Absinth. A liquor prepared from the leaves and flowers of Artemisia or wormwood (one of the *Compositæ*), together with other aromatic herbs; yellowish-green colour. Contains oil of wormwood as distinctive ingredient; flavouring oils such as peppermint, cloves, etc.; alcohol (about 50 per cent.)

Absolute Alcohol (*Chem.*) *See* ALCOHOL.

Absolute Pressure (*Phys.*) Pressure measured from the true zero or absolute vacuum. Thus a steam pressure commonly quoted as 50 lb. per square inch is 65 lb. if measured from the absolute zero or true vacuum, but is 50 lb. more than the pressure of the atmosphere.

Absolute Strength (*Eng.*) The total load necessary to break a piece of material.

Absolute Temperature (*Phys.*) Temperature measured from the absolute zero (*q.v.*) This is about 274° C. or 493° F. below the melting point of ice. Thus 20° C. = 274° + 20° = 294° absolute on the Centigrade scale; 62° F. = 62° − 32° + 493° = 520° absolute on the Fahrenheit scale.

Absolute Unit of Current (*Elect.*) A current which exerts unit magnetic force (1 dyne per unit pole) at the centre of an arc of the conductor carrying the current, the arc being of unit length (1 cm.) and unit radius. This unit is too large for practical use, and the Ampère, which is one-tenth of an absolute unit, is used instead.

Absolute Units (*Phys.*) Units connected by a simple physical relation with certain fundamental units, usually three in number, the units of Time, Length, and Mass. Thus a unit of volume directly derived from the unit of length is an absolute unit—*e.g.* a cubic foot or cubic centimetre. A poundal or a dyne (*q.v.*) is also an absolute unit of force, while the weight of a pound or of a gram is not, since it depends on the force exerted by gravity at the place as well as on the fundamental units.

Absolute Zero (*Heat*). The temperature at which no heat would remain in a body. It is found that this would be the case if we could cool a substance to −273° or −274° on the Centigrade scale. At this temperature the vibrations constituting the heat energy of the substance would have entirely ceased. The absolute zero has been approached to within about 25°; *i.e.* bodies have been cooled to − 250° C.

Absorptiometer (*Phys., Chem.*) An instrument for measuring the solubility of gases in water or other liquids.

Absorption (*Physiology*). The term applied to the process by which the soluble food materials in the stomach and intestines become diffused into the blood (*see* ILEUM, VILLI). In Botany the term used for the process by which the soil water passes into the roots. *See* ROOT.

——, **Electrical.** The storing up of a part of the electrical energy of a charged condenser by the dielectric (*q.v.*) This stored energy becomes manifest after the condenser has been discharged once by giving a second smaller discharge, followed by others still smaller. These apparent successive charges are called "Residual Charges" (*q.v.*)

Absorption of Gases, Coefficient of (*Phys.*) The volume of a gas which can be absorbed by unit volume of a given liquid at 15° C.

Absorption of Light. When light falls upon a medium, a part is usually retained or absorbed by the medium. The energy of the absorbed light commonly, though not always, is retained by the body in the form of heat; it may, however, produce some chemical change or, in the case of organic media, some physiological change.

Absorption Spectrum. *See* SPECTRUM ANALYSIS.

Absorption, Thermal. The power of a surface to absorb heat falling upon it.

Absorptive Power (*Heat*). The fraction of the total amount of heat falling upon a body, which is absorbed by the body.

Abt Rack (*Civil Eng.*) *See* MOUNTAIN RAILWAYS.

Abutments (*Eng., etc.*) Surfaces of a structure which support the load—*e.g.* the top of the piers carrying the girders of a bridge, or the part of the masonry from which an arch springs *See* ARCH.

Abyssinian Gold. A gold-plated alloy of copper and zinc.

Acacia. *See* WOODS.

Academic (*Art*). What is drawn according to rule, correct, but formal and uninspired. Academic size, a little less than half size.

Academician. A member of an academy. A Royal Academician (*R.A.*) is one of the forty members who, with a certain number of Associates, constitute the Royal Academy in England.

Academy. Originally the grove or garden near Athens where Plato taught. Now generally used for a school or a place of instruction.

——, **Royal.** Founded by George III. in 1768, under the title of the "Royal Academy of Arts in London." Established until 1834 at Somerset House, then in Trafalgar Square, since 1869 at Burlington House, Piccadilly. Consists of forty Academicians styled "R.A." and thirty Associates styled "A.R.A." The annual exhibition of pictures by living artists opens on first Monday in May, and continues until first Monday in August. Works that have once been exhibited are not again accepted for this exhibition. The winter exhibition, consisting of loan collections, etc., is open from the beginning of January until the middle of March. In the building are schools of art for male and female students. The following is a list of Presidents, with date of election: Sir Joshua Reynolds (1768); Benjamin West (1792); Sir Thomas Lawrence (1820); Sir M. A. Shee (1830); Sir C. Eastlake (1850); Sir Francis Grant (1866); Lord Leighton (1878); Sir John Everett Millais, Bt. (1896); and Sir E. J. Poynter, Bt., the present occupant of the office (1896).

Acanthus (*Architect.*) A conventional ornament used in Greek, Roman, and Renaissance architecture. It resembles the foliage of the plant of the same name. There are two types of acanthus: the "prickly," having pointed leaves, and used by the Greeks; and the olive acanthus, which has blunt leaves, and was used in Roman work. *See* COMPOSITE, CORINTHIAN.

A Capriccio (*Music*). At the caprice of the performer.

Accelerando (*Music*). Gradually quickening the speed.

Acceleration (*Phys., Mech.*) The increase of velocity per unit of time: more exactly, the rate of increase of velocity.

Accent (*Music*). Stress, prominence.

Accent (*Typog.*) A mark placed over a letter either to qualify its sound or to denote abbreviation; thus, é acute, è grave, ê circumflex, ë diæresis, ē long, ĕ short.

Acciaccatura (*Music*). A crushed note. It is distinguished from the Appoggiatura by having a stroke through its tail, and is played as a very short note.

Accidental Lights (*Paint.*) Rays of light which make some parts of the picture more prominent than the rest.

Accidentals (*Music*). Signs used during a piece to temporarily alter the pitch of a note. *See* SHARP, FLAT, NATURAL.

Accident Cranes (*Eng.*) *See* CRANES.

Accipenser (*Zoology*). A genus of the sturgeon tribe of Ganoid fishes. *A. sturio*, the common sturgeon, is a valuable food fish, and is also the source of ISINGLASS and CAVIARE (*q.v.*)

Accolé (*Her.*) is the term used by the French heralds for "collared." It also means two separate shields placed side by side—*e.g.* the knight of an order on marriage.

Accosted (*Her.*) When charges are placed side by side.

Accrued (*Her.*) Full grown, as of a tree.

Accumulator (*Eng.*) A vessel used for storing water under pressure to be used for driving hydraulic machinery. Usually consists of a vertical cylinder with a piston carrying a heavy load on the top of the piston rod.

——, **Electrical.** An accumulator, or, as it is otherwise called, a STORAGE CELL or SECONDARY CELL, is an arrangement by which electrical energy can be stored up. It consists of surfaces of lead which are coated with one of the lower oxides of lead (red lead or litharge). The leaden plates thus coated are placed in dilute sulphuric acid, and are then charged by the passage of a strong current of electricity for some considerable time. Chemical action of a kind described below occurs, and, when this is complete, the cell is fully charged. On disconnecting the wires by which it is charged, the cell will retain its energy for a considerable time; and on connecting up to any electrical apparatus, it will furnish a current with a voltage of about 2·1 volts for each cell, and this goes on until the cell is exhausted, the time taken depending upon the rate at which the current was taken from the cell. The cell can now be re-charged and the operation repeated a great number of times.—CHEMICAL ACTION IN THE CELL: The leaden plates appear first of all to become covered with a layer of lead sulphate, formed by the action of the sulphuric acid on the lead and lead oxide, with which they were originally coated. When the charging current is passed through the cell, the dilute sulphuric acid is broken up into anions, consisting of SO_4, and cations of H (nascent hydrogen). The hydrogen ion appears at the cathode or plate by which the current is leaving the cell; it attacks the lead sulphate, and gradually reduces it to a layer of metallic lead, which is left in a finely divided and spongy condition. The SO_4 ion travels to the anode, where its oxygen oxidises the lead compound to lead peroxide (PbO_2). When all the lead sulphate which is available has been acted on in this manner, the hydrogen and oxygen are set free at the plates in the gaseous form, and bubble up through the liquid, showing that the charging process is now complete, and the current may be cut off. When the cell is discharged it sends a current in the opposite direction to the one used for charging, and has a potential difference between the plates of about 2·1 volts at the start, and this gradually falls to about 1·8 volts by the time the cell is practically exhausted. Accumulators provide a chemical method of storing electrical energy, about 80 per cent. of the energy used in charging being recovered. The rate at which the energy is recovered depends entirely upon the amount of current taken from the cell, and the capacity of a cell is usually estimated in "AMPÈRE HOURS": thus, if we say that the capacity of a cell is 100 Ampère hours, we mean that it can supply 1 Ampère for 100 hours, 2 Ampères for 50 hours, 5 Ampères for 20 hours, and so on. One of the great objections to storage cells is the great weight, owing to the use of large masses of lead. The metallic lead in the cell only serves as a support for the lead compounds taking part in the reactions, and theoretically these leaden supports may be reduced to comparatively small weight; but in practice it is not safe to make the plates too slender in structure, as their surfaces are always attacked to some extent by the actions which are going on, and they would easily fall to pieces unless made fairly substantial. The actual weight of a cell which is required to furnish a certain number of Ampère hours depends upon the proportion between the active material of the cell and the inactive material or metallic lead which is unchanged during the action of the current. In the original cells used by Planté the coating of oxides of lead was formed by immersing ordinary leaden plates in a dilute acid, passing the current, then discharging, and repeating this process a number of times. Cells made in this way are sometimes termed "Formed cells," and their capacity may be put down as being from 6 to 9 Ampère hours per pound weight. In the later forms of cell which were introduced by Faure the active material consists of a paste of oxides of lead supported in frames or grids of lead. It is easily seen that in this case the amount of active material must be very much greater, and, as a matter of fact, the capacity of these "Pasted cells," as they are called, is from 10 to 15 Ampère hours per pound weight of cell.—MANUFACTURE OF CELLS: It is impossible to describe in detail the great variety of processes used in the production of different cells, and one example only is given—that of a modern form of "Chloride cell." Lead chloride specially prepared is fused and cast into small tablets of the shape of a hexagon. These tablets are arranged on a frame, leaving regular spaces between them, being held in place on the frame by small pins which fit into holes cast in each tablet. The spaces between the tablets are now filled up by pouring metallic lead in under great pressure. On cooling, there is then produced a strong frame of lead carrying a great number of lead chloride tablets, so that the greater part of the surface of each plate will consist of the chloride. The lead chloride is then reduced to metallic lead by the action of zinc in a solution of zinc chloride, and a final result is to produce a leaden plate consisting of a great number of small masses of very porous lead held in place by a kind of honeycomb of solid lead. The plates are then ready for their first charging.—EDISON'S STORAGE CELL: Many inventors have endeavoured to reduce the weight of accumulators, and Edison in some recent patents has made considerable progress in this direction. As the result of a great number of experiments, he has abandoned the use of lead altogether. The

positive plate consists of a light perforated case of sheet nickel serving as the support, and containing oxide of nickel as the active material. The negative plate also consists of a nickel case, but contains very finely divided iron, which has been reduced from the sulphate or hydrate. The liquid used in this case is a solution of an alkali; for example, NaOH in water. This cell appears to have a very much greater capacity in proportion to its weight than the ordinary pattern of storage cell; but up to the present it has hardly passed beyond the experimental stage.—G. F. G.

Acerra (*Archæol.*) The small box in use at sacrifices to hold incense, and from which the incense was poured on the burning sacrifice.

Acetabulum (*Archæol.*) A vinegar cup. Applied to all small vases wide and open, whether made of earthenware or metal. Also used by jugglers.

—— (*Zoology*). The socket in the hip girdle for the articulation of the femur or thigh bone.

Acetal, $CH_3CH(OC_2H_5)_2$. A compound formed by the union of 1 molecule of aldehyde with 2 molecules of alcohol. It is a pleasant-smelling liquid.

Acetaldehyde, CH_3CHO. Formed by heating a mixture of calcium formate and acetate; also by oxidising alcohol with chromic acid. It is a liquid boiling at 20° C. It has a peculiar smell, its vapour producing cramp of the respiratory muscles. It has the properties of an aldehyde (*q.v.*) On polymerisation it forms (*a*) paraldehyde $(CH_3CHO)_3$, a liquid which is a valuable sleep-producing agent; (*b*) in the cold, a solid metaldehyde $(CH_3CHO)_n$.

Acetamide, CH_3CONH_2. White crystals smelling strongly of mice, unless pure; melts at 82·3°; readily soluble in water and alcohol; less soluble in ether. *See also* AMIDES.

Acetanilide, $C_6H_5NHCOCH_3$ (*Antifebrin*)) A scaly crystalline solid formed by boiling aniline and glacial acetic acid together. It is poisonous. Contained in "Headache" or "Daisy" powders. It relieves pain to some extent, but depresses the heart, and should not be taken unless under medical advice.

Acetic Acid, CH_3COOH. A liquid which solidifies at 16·7° C. It is formed when weak alcohol, such as wine or malt liquor (beer), ferments under the influence of the myooderma aceti (mother of vinegar) in presence of air. The dilute acetic acid so obtained is called wine vinegar or malt vinegar respectively, and contains 5 to 15 per cent. acetic acid. The strongest acid, called glacial acetic acid (97 per cent. and over), is obtained from the pyroligneous acid produced in the destructive distillation of wood; has a powerful smell, and blisters the skin.

Acetic Anhydride, $(CH_3CO)_2O$. The anhydride of acetic acid. It is obtained by the action of phosphorus oxychloride on sodium acetate. A liquid boiling at 137°. A very important reagent in organic chemistry; used to introduce acetyl groups into hydroxyl and amino compounds, and as a condensing agent.

Acetic Ether. *See* ETHYL ACETATE.

Acetone, CH_3COCH_3 (*Dimethyl Ketone*). A liquid with characteristic smell; boils at 56°; obtained by heating barium or calcium acetate, and on the large scale from wood spirit (*q.v.*) It is used in making chloroform, iodoform, and sulphonal. The breath and urine of persons suffering from diabetes smell of acetone, and the latter occurs in considerable amount in diabetic urine. *See* KETONES.

Acetonitrile. *See* NITRILES.

Acetophenone, $CH_3COC_6H_5$ (*Phenylmethyl Ketone*; also called *Hypnone*). A low melting (20·5° C.) solid with persistent smell of oil of bitter almonds. In small doses it produces sleep. *See* KETONES.

Acetyl Chloride, CH_3COCl. This is the chloride of acetic acid, and is obtained by acting on the latter with phosphorus trichloride. It is a colourless, strongly fuming liquid of great value in organic chemistry for ascertaining the presence of hydroxyl and amino groups in compounds and in the preparation of ketones and tertiary alcohols.

Acetylene, C_2H_2. A gas which burns in air with a very bright flame; hence its use as an illuminant. Only slightly poisonous. Air containing 20 per cent. of it proves fatal to dogs. It does *not* combine with the hæmoglobin of the blood. Mixed with the proper proportion of air (1 : 12·5), it explodes with extreme violence on ignition; also decomposed by shock. Coal gas contains ·06 per cent. It is formed by the action of water on calcium carbide, when coal gas is incompletely burned, and when alcoholic potash is heated with ethylene bromide.

Achene (*Botany*). A one-seeded, dry, indehiscent fruit, such as the "seed" of the sunflower.

Achlamydeous (*Botany*). When both whorls of the perianth of a flower are absent.

Achromatic Lens. A lens which is corrected so as to bring the coloured rays which are of the greatest importance to a common focus. These rays are not the same in photography as those which are used in telescopes or microscopes, as the rays of greatest photographic importance are distinct from those which are most active in producing vision.

Achromatism (*Light*). The property of transmitting a beam of light without splitting it up into any of its component colours. Produced in lenses by a combination of two, or more, lenses of different kinds of glass, in most cases by a convex lens of crown glass and a concave lens, of less power, of flint glass.

Acicular (*Botany*). A term applied in the description of a leaf when it is long and needle-like. as in the pine.

Acid (*Chem.*) An acid is a compound which, when in aqueous solution, contains hydrogen in the ionic condition. Popularly speaking, an acid is a substance having a sour taste, turning blue litmus red, forming with basic oxides a salt and water, and often having its hydrogen replaced by direct action of certain metals, again forming a salt. When an acid forms only one salt with a monovalent metal, it is called monobasic; when only two salts, dibasic, etc.

Acid Dyes (*Chem.*) Dyes which, in order to fix them upon a fabric, require to be combined with a substance of basic character. They are generally phenols (*q.v.*) or sulphonic acids (*q.v.*) *See also* DYES AND DYEING.

Acidimetry (*Chem.*) The determination of the amount of acid in any given substance by adding a solution of an alkali of known strength from a burette to a solution of the substance until the acid is just neutralised. The neutral point is ascertained by adding to the acid solution a drop or two of a suitable indicator. *See* INDICATORS.

Acid Oxides (*Chem.*) *See* OXIDES.

Acid Process (*Metallurgy*). The early form of the Bessemer process of steel making, in which the converter had a lining containing a high percentage of

silica. This silicious or "acid" lining fails to remove phosphorus from the iron, and has been replaced by the "Basic Process."

Acid Pump (*Chem.*) A pump with internal parts made of glass or earthenware, so as to be unaffected by acids.

Acid Rocks (*Geol.*). A term referring to the chemical composition of certain rocks of eruptive origin. These consist mostly of silicates of various bases, in which the proportion of silica, which functions as the acid element, to the base is subject to a wide range. Those cases in which the percentage of silica falls below 55 or 60 are referred to as BASIC; those in which it is between 55 and 65 are spoken of as INTERMEDIATE; while the rocks in which a higher silica percentage obtains are the ACID ROCKS here specially referred to.

Acierage (*Engrav.*) A process by which a very thin layer of steel is deposited on the face of an engraved copperplate so that it may stand the wear and tear of printing; somewhat similar to electroplating.

Acinaces (*Archæol.*) A Persian sword, short and straight like a dagger, generally worn against the right thigh.

Ackerman Axle (*Motor Cars*). The original type of most forms of steering in cars. The main shaft is rigidly fixed to the car, short-axles are pivoted or hinged to the ends of this, and on these short axles the hubs of the wheels run. The hinges are operated by levers connected with the steering wheel. The pivot or hinge varies in form, and is the subject of various patents.

Acketon, Aketon, Hacketon (*Cost.*) A quilted garment worn over the shirt to prevent armour from injuring the body.

Aconite (*Botany*). *Aconitum napellus* (order, *Ranunculaceæ*). The preparations of aconite are made from the dried root, the fresh leaves, and the young inflorescences.

Aconitine, $C_{21}H_{27}.(OCH_3)_4.NO_5.COCH_3.COC_6H_5$. An alkaloid obtained from aconite root (monk's hood or wolf's bane). It is a crystalline solid, intensely poisonous. Externally it causes tingling numbness and local anæsthesia; internally, tingling numbness, vomiting. It dilates the pupils of the eye.

Acratophoron (*Archæol.*) A vessel for holding pure wine, *i.e.* unmixed with water.

Acre. *See* WEIGHTS AND MEASURES.

Acridine, 
A white crystalline solid occurring in coal tar. Inhaled, it causes sneezing. Its solutions show a blue fluorescence. Some of its derivatives are important as dyes.

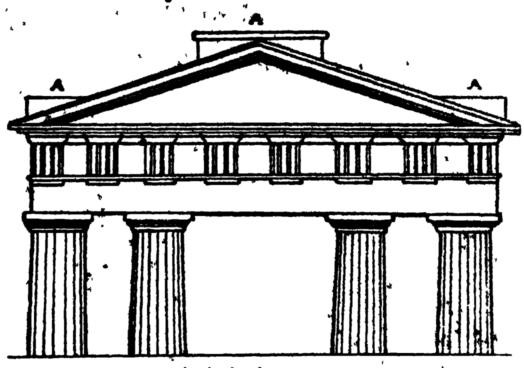
Acrolein, $CH_2:CH.CHO$. A colourless mobile liquid boiling at 52°; it has an extremely pungent smell. Its chemical behaviour is that of (1) an unsaturated compound (*q.v.*), (2) an aldehyde (*q.v.*) It is formed when glycerine is heated with water, abstracting reagents such as sulphuric acid or potassium acid sulphate.

Acromion (*Zoology*). A process at the end of the ridge on the outer surface of the scapula or shoulder blade.

Acropolis (*Architect.*) The citadel of a Greek city, usually situated at the summit of the hill upon which the city was built.

Acrostolium (*Archæol.*) "At the head of the prow there projected the stolos, and its extremity, which was frequently made in the shape of an animal or helmet, was called acrostolium. It is sometimes designated by the name cheniscus" (*q.v.*).—SMITH.

Acroterium, *pl.* **Acroteria** (*Architect.*) Small pedestals resting on the angles of a pediment and intended to carry statues or other ornaments.



A, A, A, ACROTERIA.

Acrylic Acid, $CH_2:CH.COOH$. A liquid boiling at 140°, and smelling like acetic acid; formed by oxidation of acrolein with silver oxide and by abstracting water from hydracrylic acid.

Actaeon. *See* ARTEMIS.

Actinolite (*Min.*) A variety of Amphibole (*q.v.*) occurring usually in fibrous and radiated crystalline masses (*Actinotos*, radiated). Common in metamorphic rocks. A silicate of iron, calcium, and magnesium. Monosymmetric. Composition: $3(Mg.Fe)O.SiO_2.CaO.SiO_2$.

Actinometer (*Photo.*) An instrument for measuring the photographic intensity of light, and hence the time of exposure. It usually depends on the observation of the time necessary to darken a sensitised strip of paper.

Actinomorphic (*Botany*). The term used when a flower is radially symmetrical—that is, when the flower can be divided into similar halves by two or more planes passing through an axis.

Action at a Distance (*Physics*). Phenomena such as electric and magnetic attractions and repulsions were supposed by the older physicists to be due to some obscure power of action at a distance. Such forces are now explained by the existence of stresses and strains in the medium connecting the bodies acted on. *See* LINES OF FORCE.

Active Current (*Elect. Eng.*) The component of an alternating current which is in phase with the impressed electro-motive force. If C is the full amount of current and ϕ is the angle of lag, then the active current is $C \cos \phi$.

Acuminate (*Botany*). The term applied to the apex of a leaf when it is drawn out to a point.

Acus (*Archæol.*) A needle or pin, generally made of metal.

Acute Accent (*Typog.*) A mark placed over a letter, thus é: opposed to grave.

Acute Angle. One less than a right angle (90 degrees).

Adagio (*Music*). Slow, leisurely.

Added Sixth (*Music*). The common chord on the Subdominant, with an interval of a sixth from the bass added: also called the third inversion of the Dominant 11th.

Addendum (*Eng.*) The point of a wheel tooth or part outside the pitch circle (*q v.*)

Addorsed, Adorsed (*Her.*) Back to back; the opposite of *affronté*.

Adhesive Power (*Eng.*) The friction between the driving wheel of a locomotive and the rail which prevents slipping. Varies from one-fifth to one-twelfth of the weight, according to the state of the rails, being least when the rails are moderately wet or "greasy."

Adiabatic Change (*Phys.*) Any change in the pressure and volume of a gas during which no heat is allowed to enter or leave.

Adiabatic Curve (*Phys.*) A curve showing the relation between the pressure and volume of a gas when no heat is allowed to enter or leave while the gas is compressed or expanded. (This relation is expressed algebraically by the equation $PV^\gamma =$ constant, where γ is the ratio of the specific heats at constant pressure and constant volume.)

Adipose Tissue (*Zoology*). The term applied to the connective tissue, whose cells are distended by fat drops. Fatty tissue forms a thick layer beneath the skin of animals and also around the kidneys.

Adit (*Mining*). A passage or "level" from the open air into a mine; if it runs to the vein, it is termed a "tunnel."

Adjustable Level. A level (*q.v.*) in which the tube containing the bubble can be moved through a small angle relatively to the "stock" or case, in order to get the axis of the tube accurately parallel to the sole or base of the instrument. The levels on surveying instruments are always made adjustable.

Adjusters, Chain (*Cycles*). Small bolts with eyes through which the back axle passes, and by means of which the latter can be moved in the slots of the fork ends.

Adjusting Screw. A fine threaded screw for regulating the position of some part of a machine or piece of apparatus.

Adjustment of Brushes (*Elect.*) *See* BRUSHES.

Adjutage, Ajutage (*Eng.*) An outlet for the flow of a liquid from a vessel.

Ad Libitum (*Music*). (1) At the pleasure of the performer. (2) The part *ad lib.* may be omitted.

Admission (*Eng.*) The moment at which steam enters a cylinder; also the whole period during which it is entering.

Admission Corner (*Eng.*) The part of an indicator diagram (*q.v.*) showing the entrance of the steam. For a rapid entry of steam the corner should be sharp and square; if too much rounded, it shows that steam enters too slowly, that is, the admission port is opened too late or is too small.

Admission Line (*Eng.*) The side of the indicator diagram showing the conditions while steam is entering. It should be nearly upright. *See* INDICATOR DIAGRAM.

Admission Port (*Eng.*) The passage by which steam enters the cylinder of an engine.

Admission Valve (*Motor Cars*). *See* PETROL ENGINE.

Adrenal Body (*Zoology*). The adrenal or supra-renal body is a small organ found in relation to the kidney. An extract is used in medicine.

Adriatic. *See* BUCENTAUR.

Adularia (*Min.*) A colourless sub-transparent variety of orthoclase, one of the felspars (*q.v.*) A sub-variety is MOONSTONE, so called from its pale moonlight-like lustre.

Adulteration of Food. This important matter is regulated by various legislative enactments in force throughout the country. These are: Sale of Food and Drugs Act, 1875; Sale of Food, etc., Amendment Act, 1879; Margarine Act, 1887; Sale of Food and Drugs Amendment Act, 1899. In order to see that these Acts are not contravened, samples are taken and analyses made by the local authorities. The experience is that nearly all our foods are adulterated, generally by the admixture of foreign ingredients. Milk is the food that is chiefly adulterated. Being of the highest dietetic value, and constituting, as it does, the principal food of children up to some eighteen months of age, it is extremely important that no contamination should take place.

Advancing Ignition (*Motor Cars*). Causing the spark to ignite the charge sooner. This is effected by turning the contact breaker on the secondary shaft (*q.v.*), so that it comes sooner into contact with the ignition cam (*q.v.*) By turning the contact breaker in the opposite direction, the spark (and therefore the ignition) is retarded.

Adventitious (*Botany*). The term used when an organ is developed out of its proper order, as in buds where developed without relation to leaves, or in roots where they arise on stems, leaves, etc.

Adze (*Carp.*) A tool of the nature of an axe, but with the plane of the blade at right angles to the axis of the handle. Used for cutting broad surfaces of wood, and formerly a common tool in shipyards.

Adze Block (*Carp.*) The part of a wood-planing machine which carries the cutters.

Ægipan. Beasts fashioned partly like men, but having the horns and feet of a goat: satyrs.

Ægis (literally, *Goat skin*). The shield carried by Jupiter and Minerva, made of the skin of the goat Amaltheia, with a gorgon's head in the centre. Also a breastplate worn by Roman emperors.

Æolian Rocks (*Geol.*) The majority of the derivative rocks composing the stratified formations have been formed and deposited by the direct and exclusive agency of water; but in regions where an arid climate prevails the agency of the wind comes largely into play, both in giving form to the constituents of rocks and in their final distribution afterwards. Many sandstones belonging to the New Red, and some belonging to the Old Red, are of Æolian origin.

Aërial Rocks (*Geol.*) A term applied to certain rocks which have been formed on the surface of the land, and not beneath water, or in connection with ice. It is usually applied to such rocks as peat, blown sand, clay with flints, screes, rain wash, dust deposits, and the like; but it is not generally used in referring to the products of volcanic action.

Aërobic (*Botany*). The term used for those bacteria which live only in the presence of oxygen.

Æsculapius. God of medicine. He is represented with a staff and a serpent.

Æsthetics (*Art*). Perception or appreciation of the beautiful.

Æstivation (*Botany*). The term applied to the arrangement of the parts of a flower bud before the flower opens.

Affetuoso (*Music*). With feeling.

Affinity (*Chem.*) Is the name given to the unknown cause which determines the occurrence of a chemical change. While the nature of affinity is unknown, something is known of the conditions affecting its action—such are temperature, pressure, light, etc.; and something is known of the laws of its action—such as the law of mass action (*q.v.*)

Affronté, Affronted (*Her.*) Of two animals when facing each other; of one animal when it is full faced.

After Blow (*Met.*) The forcing of air into a Bessemer converter after the carbon has been removed, in order to oxidise the phosphorus. In the acid process (*q.v.*) the after blowing was apt to injure the iron by setting up oxidation. In the basic process (*q.v.*) there is less risk of this.

After Burning (*Gas Engines*). The continued combustion of the charge after the explosion has occurred.

After Damp (*Mining*). The name given by miners to the gases produced by an explosion in a coal mine. Among them are carbon dioxide, which is not very poisonous, but would cause death from asphyxia when present to the extent of about 10 per cent. by volume; and carbon monoxide, which is intensely poisonous.

After Flush (*Plumbing*). The after flush performs an important function in "sealing" up the trap of the water closet after the contents of the basin have been discharged into the soil pipe. If this was not done, foul air would gain access to the water closet apartment, and be then ventilated into other parts of the house.

Agar-Agar. A nutritive jelly used in bacteriological work, derived from various Red Sea weeds (*Rhodophyceæ*). *Gracilaria lichenoides* yields the Ceylon agar, while *Eucheuma spinosum* is the source of the Java agar.

Agate (*Min.*) Chalcedony having a well banded appearance; now more often confined to chalcedony deposited in the vapour cavities of lavas. MOSS AGATE contains fine dendrites of oxide of iron. VEIN AGATE and RIBBON JASPER are usually forms of chalcedony deposited in veins. Agates are much used as ornamental stones. *See also* PRECIOUS STONES.

Ageing of Transformer Cores (*Elect. Eng.*) The deterioration of cores by use. The magnetic properties of the iron gradually decay, and the loss of energy by hysteresis (*q.v.*) becomes greater.

Agglomerate (*Geol.*) It was formerly the custom to name all the coarser materials arising from the explosive eruptions of volcanoes AGGLOMERATE, whether they had fallen back within the volcanic vent or outside of it. Latterly it has been deemed advisable to employ the term TUFF for the latter, irrespective of the size of the fragments, and to use the word AGGLOMERATE for the fragmentary material, whether coarse or fine, that fills the volcanic vent or NECK.

Aggregate (*Building*). Ballast, broken bricks, etc., that are mixed with lime or cement to form concrete.

Agitato (*Music*). Agitated.

Agitator (*Met.*) A stirrer used to mix the contents of the Bessemer converter after pouring out. Also applied to stirrers in various chemical manufacturing processes.

—— (*Paper Manufac.*) A paddle used for mixing the paper pulp in the stuff chest.

Agonic Line (*Magnetism*). A line drawn on a map connecting places at which there is no magnetic declination—*i.e.* where the compass needle points due north.

Agora. The public square and place of assembly in ancient Greek towns, corresponding with the "Forum" of the Romans.

Aich Metal (Gedge's Metal). An alloy resembling brass: copper, 60; zinc, 38·2; iron, 1·8.

Aiglets, Aglet (*Cost.*) A tag of metal (termed a point) used on fastenings of costume or armour.

Aigrette (*Cost.*) Called after the beautiful crest of feathers on the egret at the nesting season. Applied to a spray of feathers worn in a head-dress, or a tuft in a helmet, or a spray of gems as worn by Eastern princes.

Ailette (*Armour*). A wing-like projection from the shoulder, made of leather, but sometimes of steel. On it was emblazoned a charge from the coat of arms of the wearer.

Ailsenite (*Min.*) A rare sulpho-bismuthinite of lead and copper, $3(PbCu_2)S \cdot Bi_2S_3$. Occurs in blade-like crystals in a quartz matrix with native gold and some nickel ores in Siberia.

Air. *See* ATMOSPHERE.

Air Belt (*Met.*) A channel running round a cupola furnace (*q.v.*), from which the air enters the furnace by a number of openings, thus obtaining a more uniform distribution of the blast than is possible from two or three tuyers or nozzles.

Air Blast (*Elect. Eng.*) Used (1) for cleaning parts of dynamos from dust; (2) for blowing out the spark at a commutator.

Air Brake (*Eng.*) A brake in which the blocks are moved by pistons actuated by air pressure.

Air Brick (*Building*). A brick perforated with holes for ventilation.

Air Casing (*Eng.*) A space surrounding a flue, boiler, etc., intended to prevent the undue transmission of heat to surrounding objects.

Air Channels (*Met.*) Spaces beneath the hearths of various furnaces, serving the same purpose as an air casing (*q.v.*)

Air Compressor (*Eng.*) A pump for driving air under pressure into a reservoir for use in ventilation or to supply motive power.

Air Cooling (*Eng.*) Term applied to petrol motor engines in which the waste heat from the cylinder is dissipated into the air by means of flanges and corrugations on the cylinder itself. Only small engines are air cooled; larger ones are water cooled (*q.v.*)

Air Crucible Furnace (*Met.*) *See* BRASS FURNACE.

Air Cushion (*Eng.*) In high-speed engines, when made single acting, the piston compresses a quantity of air which is enclosed in the opposite end of the cylinder; this prevents the stresses in the reciprocating parts from being reversed, and therefore keeps

the reciprocating parts from the shocks which reversals of stress would cause. In the Willans engines, much used for electric lighting work, the piston rod and its adjuncts are kept in compression; in Mather & Platt's high-speed electric lighting engines the rods are in tension during both strokes.

Air Cylinder (*Plumbing*). An air chamber in a valve closet to regulate the flush.

Air Engine (*Eng.*) An engine in which the piston is moved by air heated in a large vessel (partly corresponding to the boiler of a steam engine). Air engines are practically obsolete even for the smallest powers.

Air Feed Pumps (*Motor Cars*). Small pumps for keeping up the air pressure in the fuel tanks of steam cars; this air pressure is needed to drive the oil fuel to the burner.

Air Flue (*Building*). A flue formed in a chimney stack for extracting the foul air from a room. *See also* ARNOTT'S VALVE.

Air Gap (*Elect. Eng.*) The narrow space between the pole pieces and the iron of the armature, or any gap (containing no iron) in a magnetic circuit.

Air Gate (*Foundry*). A vertical hole in a mould allowing the free escape of air while the molten metal is being poured in.

Air Hole (*Eng., etc.*) A small opening to allow the escape of air, where necessary, from some internal part of a machine or apparatus.

Air Lock (*Civil Eng.*) A chamber with doors at each end, one opening to the air, the other into a tunnel or other space filled with compressed air. Admission to the tunnel is gained through the air lock without the loss of pressure in the contained air which would occur if the tunnel were put into direct communication with the atmosphere.

Air Manometer (*Physics*). An instrument for measuring fluid pressure by means of the compression of air enclosed in a tube sealed at one end. The pressure is usually transmitted to the air by a column of mercury which fills the lower part of the tube, the other end of the column being exposed to the pressure to be measured.

Air Pumps. An air pump is an apparatus for "exhausting" or pumping out the air from any vessel, thereby producing what is called a "vacuum." No air pump really produces a vacuum in the strict sense of the word, inasmuch as there is always a certain quantity of air or other gas left in the space. The amount of this gas is best estimated by means of the pressure which it exerts on the walls of the vessel, the pressure being measured, as usual, in millimetres of mercury. A vacuum is required not only in a great number of chemical and physical experiments, but in various pieces of apparatus for the artificial production of cold, in tubes for Röntgen ray and other electrical work, and in the bulbs of incandescent lamps. Air pumps may be divided into two classes: MECHANICAL AIR PUMPS and MERCURY AIR PUMPS. The simplest form of mechanical pump is shown in fig. 1. A is a metal cylinder of smooth and uniform bore, in which a piston (B) is moved up and down by the piston rod C. B must fit the cylinder, or "barrel," as it is termed, as closely as possible, in order to be air tight. The tube D communicates with the vessel to be exhausted, and is closed at the top by a valve (E), consisting of a flap of oiled silk opening inward—*i.e.* towards the interior of the barrel. On raising the piston, air is drawn through the valve E into the barrel; when the piston is depressed, this air is forced out through the valve F in the piston, which is a similar valve to the one at E. The air which had been drawn into the barrel is thus expelled, and on raising the piston again, the valve F closes, and a further supply of air is drawn in through the tube D. This process goes on until a sufficient vacuum is obtained; but it cannot be carried beyond a certain degree of exhaustion, as the valves, being opened by the pressure of the air, will not work after the latter has fallen below a certain amount. Various attempts have been made to get over this difficulty with the valves by means of mechanical contrivances; but although it is possible to effect certain improvements by such means, no very high degree of efficiency has been reached. A great improvement in mechanical pumps has been made of recent years in what is called the FLEUSS PUMP. Fig. 2 shows the action of this pump in a diagrammatic manner. The barrel A has no valve at the foot, tubes E and F both opening into a tube (D) communicating with the vessel to be exhausted. The piston B is solid, and of such a thickness that when pushed nearly to the bottom of the cylinder, the pipe F is above its upper surface. The piston rod C passes through a cover (G), in which is a valve (H). This valve may be a comparatively heavy one, as it is not closed and opened by the pressure of the air. A layer of oil covers the top of the piston and the bottom of the barrel to the depth shown in the figure. On raising the piston, any air above it is driven out through H, and as the piston is raised, the oil above it gradually rises through the valve, completely expelling the air; when the piston falls again, the valve closes by its own weight, and a layer of oil which remains above the cover G effectually cuts off communication between the barrel and the outside air. When the piston again falls below F, air rushes through D, from the vessel which is being exhausted, into the barrel A, and is again expelled by the rising or up stroke. In this pump there is no valve whose opening depends upon the pressure of the inside air, and there is no space at the bottom of the barrel when the piston has completed its downstroke, so that the whole of the contained air is expelled. The efficiency of this pump is very great, and it is much used for the production of incandescent lamps; and, indeed, gives a sufficiently good vacuum for a great deal of vacuum tube work in electricity. The degree of exhaustion which is reached after a good number of strokes of a mechanical pump is given in the following calculation:

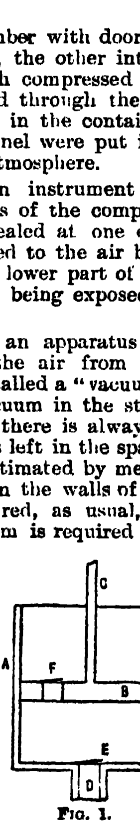


FIG. 1.

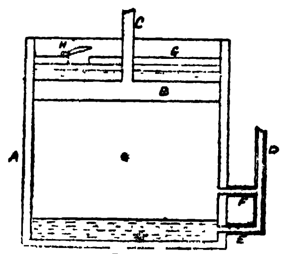

FIG. 2.

Let p = original pressure of the air.
V = volume of receiver and connecting pipes.
v = volume of the cylinder of the pump.

Then, in the first stroke, air which occupied a space V is caused to expand until it occupies a

space $V + v$. Then by Boyle's Law (*q.v.*) we get $pV = p_1 (V + v)$, where p_1 is the pressure after the first stroke is complete.

$$\therefore p_1 = p \frac{V}{V + v}$$

In the second stroke the air again expands from V to $V + v$, and its pressure falls from p_1 to p_2, where p_2 is the pressure after the second stroke is complete.

$$\therefore p_1 V = p_2 (V + v)$$

$$p_2 = p_1 \frac{V}{V + v} = p \left(\frac{V}{V + v}\right)^2$$

After the third stroke is complete we get a pressure $p_3 = p \left(\frac{V}{V + v}\right)^3$

After the n^{th} stroke,

$$p_n = p \left(\frac{V}{V + v}\right)^n$$

From this formula the pressure after any given number of strokes may be calculated.—**Mercury Pumps**: These depend in all cases on the production of the vacuum at the top of a barometer tube (*see* Barometers); but the manner in which this vacuum is utilised varies considerably in different forms of mercury pumps. Two of the main forms only will be described. The first of these is the Sprengel Pump (fig. 3). Mercury is poured into a large funnel (A), and flows through the tubes AB and BC into the "pump head" D, from which it falls down the "fall tube" DE, whose length is greater than the height of the barometer. The vessel to be exhausted communicates by means of the tube F with the tube bent at C. The mercury at first flows through DE in a nearly unbroken stream, but very rapidly breaks up into short threads of mercury with air between them, each thread acting as a kind of piston, expelling the air through the bottom of the tube DE, which dips into a suitable vessel where the mercury is collected. The action of this pump goes on continuously until the mercury in the funnel A has all flowed out. When this is the case, the action of the pump stops; but air cannot get into the tube F because a column of mercury rises in the tubes BC and ED, and as these are both longer than the barometer tube, the mercury in them cannot reach the top, and air cannot therefore get in. The Sprengel Pump will give a remarkably high vacuum, and its action, although somewhat slow, has the advantage of being very continuous. The second form is the Töpler Pump (fig. 4). In this pump a globe of fairly large capacity (A) communicates with the vessel to be exhausted by means of a tube (EF). B is a flexible tube longer than the barometer, at the end of which is a large mercury funnel (C). The latter is filled with mercury when in the position shown; it is then raised, and the mercury rises in the flexible tube B, flowing past a tube (E), and thereby cutting off communication between A and the vessel which is being

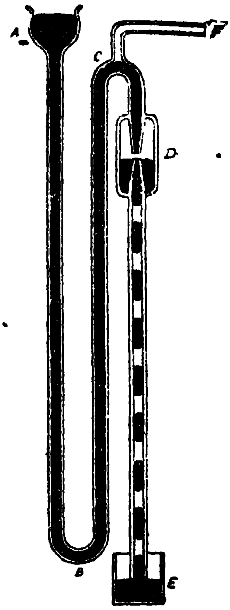

Fig. 3.

exhausted; and as C is further raised, the air is driven out of A through a tube (D), until at the end of the stroke a small quantity of mercury is also forced out of the top of A, and falls through D into a vessel placed to receive it. On lowering C, a vacuum is produced in A, and mercury rises in D. As the mercury falls below the level of the tube E, air rushes in from the vessel to be exhausted, and fills the globe A; this is again expelled at the next stroke. This process goes on until the height of the mercury column in D is practically equal to the height of the barometer, thereby showing that A and the vessel communicating with it are completely exhausted of air. In a good mercurial pump the pressure can be reduced to ·000012 of a millimetre of mercury, and in this case the height of a column, such as the one in the tube D, will be indistinguishable from the height of the barometer. The actual pressure of the contained gas must then be ascertained by some other means, such as a special form of pressure gauge known as the Macleod Gauge; or, if the vessel should be a vacuum tube, such as is used for electrical experiments, an electrical discharge passed through it will give a very good indication of the extent of the vacuum, as the electrical phenomena assume different appearances, corresponding in a well-marked manner to different degrees of exhaustion.—F. G. F.

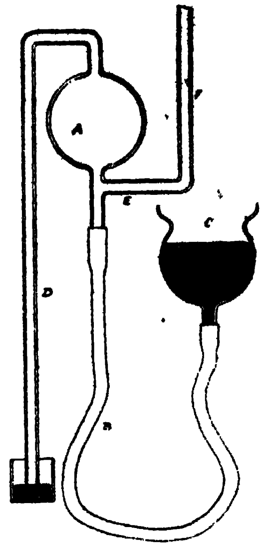

Fig. 4.

—— (*Eng.*) In engineering, a pump for removing the condensed steam, either alone or along with the water used to condense it, from the interior of the condenser into the air. This water cannot flow away by a simple opening, as there must be a partial vacuum continually maintained in the condenser, which any opening would destroy.

Air Receiver (*Eng.*) A vessel of considerable capacity sometimes placed between the blower and the furnace to render the pressure of the air more uniform.

Air Regenerator (*Eng.*) *See* Regenerator.

Air Spaces (*Eng.*) The gaps between the fire bars of a boiler.

Air Thermometer (*Heat*). An instrument for measuring a very wide range of temperatures by observing the change in pressure of a constant volume, or less frequently the change in volume at a constant pressure, of air enclosed in a suitable receptacle.

Air Vessel (*Eng.*) A vessel partly full of air, partly of a liquid, whose flow is rendered more uniform by the air above it acting as an elastic cushion, which neutralises the shocks of the pump and keeps the liquid flowing on between the strokes.

Aisle (*Architect.*) A lateral division of a church, separated from the nave or choir by columns or pillars. *See* Nave *and* Choir.

Alabaster (*Archæol.*) A small box or vase, originally made of alabaster, used for holding perfumes. There are specimens of great antiquity.

—— (*Min.*) A white granular variety of gypsum (*q.v.*); a hydrous sulphate of calcium, much used in the manufacture of plaster of Paris. This variety is chiefly found in England in the New Red Marls. Composition: $CaSO_4 . 2H_2O$. Also known as gypseous, or white, alabaster.

——, **Oriental** (*Min.*) A stalagmitic variety of calcite; of white or brownish concentric laminæ. Used as an ornamental stone under the name Algerian onyx.

Alanine, $CH_3CH . NH_2 . COOH$. α-amidopropionic acid. A decomposition product of albumin.

Alb (*Cost.*) A close-fitting ecclesiastical vestment, originally of fine linen, with apparels on the skirt before and behind, also on the cuffs.

Albertotype, Albert type, from name of inventor. A photographic plate so prepared that it can be printed from like a lithographic stone.

Albian Series (*Geol.*) A term often applied to the Gault, which English geologists regard as the lowest member in Britain of the Upper Cretaceous rock. The typical locality is near Folkestone; and the British rocks of this age mostly consist of clays of marine origin, ranging from 150 ft. to nearly double that thickness. These beds were formed in rather deep water. They afford remarkable illustrations of fossiliferous zones, in which the "zones" are mostly characterised by distinct species of organism, mostly Ammonites.

Albite (*Min.*) One of the rock-forming alkali silicates, constituting a soda felspar. Its composition, when it is quite pure, is $Na_2O = 11 \cdot 8$, $Al_2O_3 = 19 \cdot 5$, $SiO_2 = 68 \cdot 7$. Its crystalline system is anorthic. It is not uncommon as a constituent of the crystalline schists and gneisses. It sometimes occurs as a constituent within the body of granites and the rock allied to them; but more commonly it has been developed within drusy cavities in these rocks during the later stages of consolidation.

Albumen. Egg albumen, the white of the egg of the fowl (*Gallus banckivia*), is used in pharmacy and in photography. In the latter case it serves as the support or vehicle for the sensitive salts in printing papers of the older types.

—— (*Botany*). The tissue containing reserve food substances present in many seeds, and surrounding the embryo. It is also called endosperm—a preferable term, on account of the use of "albumen" for a definite chemical compound.

Albumin. A general term applied to those compounds containing carbon, hydrogen, nitrogen, oxygen, and sulphur, which form the most important constituents of living animals and plants, and give certain general reactions. They belong to the class of colloidal substances. They are coagulated on heating: precipitated from their solutions by alcohol and by certain salts, such as magnesium sulphate and ammonium sulphate: are generally amorphous solids, but some have been obtained crystallised—*e.g.* serum albumin: soluble in water, dilute acids, and alkalis: of unknown constitution. Hofmeister gives the formula $C_{450}H_{720}N_{116}S_6O_{140}$, corresponding to a molecular weight of 10166. Some of the general reactions referred to above are: (1) precipitation by the strong mineral acids; (2) precipitation by the alkaloid reagents; (3) the Biuret reaction (*q.v.*); (4) the xanthoproteic reaction (*q.v.*); (5) Millon's reagent (*q.v.*) Some of the decomposition products of albumins are glycocoll, leucine, aspartic acid, lysine, argenine, tyrosin, indole, skatole, and ptomaines (*q.v.*) For the classification of the albumins, consult a book on practical physiology. Ordinary white of egg is a typical albumin, and the name albumen is generally used for it.—W. H. H.

Albuminoids. These belong to the class of proximate principles which comprise the proteid group. They are derived from animals, are soluble in water, and contain the elements nitogren, carbon, oxygen, hydrogen, and sometimes sulphur. The albuminoids are of less nutritious value than the true proteids. At the same time, when mixed with proteids, they are of some value. In the group are gelatin, keratin, chondrin, and ossein.

Alburnum (*Botany*). The outer part (sapwood) of the wood of an old tree. It retains the power of carrying up the soil water absorbed by the roots.

Alcarraza (*Pot.*) An unglazed porous vessel for cooling water by evaporation, used largely in Spain, Egypt, and some parts of Asia.

Alcazar (*Architect.*) The Spanish name for a castle or palace.

Alcohol. This is a general term applied to any compound formed from a hydrocarbon by replacing one or more hydrogen atoms by the same number of hydroxyl (OH) groups, the hydrogen atoms replaced being attached to different carbon atoms. When only one hydrogen is replaced, we have a MONOHYDRIC ALCOHOL; when two are replaced, a DIHYDRIC ALCOHOL, and so on. There are three classes of alcohols: (1) PRIMARY, which have the formula $R - CH_2OH$, where R is a hydrogen atom or an alkyl radical (*q.v*); (2) SECONDARY, having the formula $\begin{matrix} R \\ R' \end{matrix}\!\!> CHOH$, where R and R′ are both alkyl radicals and which may be the same or different; (3) TERTIARY, having the formula

$$\begin{array}{c} R \\ | \\ R' - COH \\ | \\ R'' \end{array}$$

where R,R′,R″, are alkyl radicals which may be the same or different.

Examples:

$$\begin{array}{ccc} \begin{array}{c} CH_3 \\ | \\ CH_2OH \end{array} & \begin{array}{c} CH_2OH \\ | \\ CH_2OH \end{array} & \begin{array}{c} CH_2OH \\ | \\ CHOH \\ | \\ CH_2OH \end{array} \end{array}$$

Monohydric alcohol from ethane C_2H_6. — Dihydric alcohol from ethane. — Trihydric alcohol from propane.

$$\begin{array}{ccc} \begin{array}{c} CH_3 \\ | \\ CH_2OH \end{array} & \begin{array}{c} CH_3 \\ | \\ CHOH \\ | \\ CH_3 \end{array} & \begin{array}{c} CH_3 \\ | \\ CH_3 - C . OH \\ | \\ C_2H_5 \end{array} \end{array}$$

Primary. — Secondary. — Tertiary.

Ordinary alcohol is ETHYL ALCOHOL, $CH_3 . CH_2OH$; it is produced by the fermentation of sugar. On the large scale it is obtained by allowing malt, which contains the enzyme diastase, to act in presence of warm water on barley and wheat. The diastase converts the starch of the grain into a sugar called maltose (*q.v.*) Yeast is added to the liquid, when the maltose is fermented, and yields alcohol. The WORT, as the product is called, is then submitted to steam distillation, when RECTIFIED SPIRIT is obtained, which is a mixture of alcohol and water, containing 84 per cent., by weight, of alcohol. To obtain ABSOLUTE ALCOHOL the rectified spirit is

allowed to stand over lumps of quicklime, and then distilled again. By repeating the process it can be obtained free from water. Alcohol is a faint, pleasant-smelling liquid, boiling at 76° C. It mixes with water in all proportions. On oxidation it yields first aldehyde (*q.v.*), then acetic acid. Alcohol enters into the composition of spirits, wines, and beers. Brandy, whisky, and rum contain about 50 per cent., gin 40, port wine 20, sherry 16, claret 7, and beer 5 per cent., by weight, of alcohol in every case. *See also* ETHYLATES, ETHYL CHLORIDE.—W. H. H.

Alcohol Fuel (*Motor Cars*). Alcohol, being volatile, readily forms a vapour, which, when mixed with air, is highly explosive. In France and Germany cheap alcohol, made from potatoes or beetroot, is utilised to a considerable extent in place of petrol.

Alcoholimetry (*Chem.*) The method of estimating the amount of alcohol in a liquor. If the liquor is a mixture of alcohol and water only, this may be done by taking the specific gravity and looking out the result in a table, or by use of a Sikes' hydrometer, which is an instrument specially devised for the purpose. In the case of beer, wine, etc., a suitable fraction is distilled, so as to obtain a mixture of alcohol and water only, and the amount of alcohol is estimated in the distilled part.

Alcove (*Building*). A vaulted recess: a niche.

Aldehyde. This is a general term applied to compounds containing the group R – CHO, where R may be hydrogen or an alkyl radical (*q.v.*), but is frequently used to denote acetaldehyde (*q.v.*) Aldehydes are generally liquids: easily oxidised to acids: readily polymerising (*q.v.*): combining directly with ammonia, prussic acid, and sodium hydrogen sulphite: with phosphorus pentachloride the oxygen is replaced by two chlorine atoms. They undergo condensation (*q.v.*) *See also* OXIMES *and* HYDRAZONES.

Alder, Common. *See* WOODS.

Aldol, $CH_3.CHOHCH_2CHO$. A liquid formed by the condensation of aldehyde.

Alençon Lace. This lace is manufactured by a process very similar to Brussels lace (*q.v.*) It is made in France, and, though very beautiful, is not equal to Brussels lace. In the modern Alençon, machine-made net is generally used.

Aleurone (*Botany*). The proteid (nitrogenous) grains found as a reserve material in cells, particularly those of many seeds. They are often of large size and complex character.

Al Fine (*Music*). To the end.

Algerian Onyx (*Min.*) *See* ALABASTER, ORIENTAL.

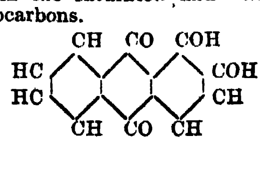
Alhambra (*Weaving*). A coarse counterpane or figured bed quilt with coloured threads, wrought by the Jacquard machine in large and ornamental designs.

Alignment (*Eng., etc.*) The correct placing in line of the parts of a machine or apparatus—*e.g.* the mandrel and loose centre of a lathe, or the front and back wheels of a bicycle.

Alinement, Alignment (*Archæol.*) Arrangement in lines. Stone avenues formed of *menhirs* or blocks of stone.

Aliphatic Compounds (*Chem.*) The compounds derived from the saturated and unsaturated open chain hydrocarbons.

Alizarin,



Orange-red needles which melt at 290°. It is found in combination as the glucoside ruberythric acid in madder root, from which it was formerly obtained. Now it is made from anthracene (*q.v.*), which, with fuming sulphuric acid, gives anthraquinone monosulphonic acid, and the latter on fusion with caustic soda and a little potassium chlorate gives sodium alizarin; addition of acid yields alizarin. It is a most important dye; with alumina as mordant, it gives *Turkey Red.* Many of its derivatives are also dyes—*e.g. Alizarin Blue,* which is used as a substitute for indigo, and is very stable. *See also* DYES AND DYEING.

Alkali. An alkali is a substance which yields, on solution in water, hydroxyl ions. Compounds such as caustic soda (NaOH), caustic potash (KOH), solution of ammonia (NH_4OH), slaked lime ($Ca(OH)_2$) can all evidently yield hydroxyl (OH) ions. Oxides, like quicklime, first form the hydroxide, *e.g.* $Ca(OH)_2$, and so on solution yield hydroxyl ions. In the case of salts of a weak acid, such as carbonic acid, which yields the alkali sodium carbonate, we have, on solution in water, the following change: $Na_2CO_3 + H_2O = NaHCO_3 + NaOH$, and in this case we again have hydroxyl ions. Alkalis have a caustic taste, turn red litmus blue, and neutralise acids, forming a salt and water. The alkalis ammonia, caustic soda and caustic potash, sodium and potassium carbonates, and quicklime (CaO) are prepared on an enormous scale. For the preparation of the first of these *see* AMMONIA: it was formerly, and is still sometimes, called the VOLATILE ALKALI, because it is readily volatilised on heating. Caustic soda and potash are often called the CAUSTIC ALKALIS, and their carbonates the MILD ALKALIS; these are all called *fixed alkalis,* because they are not readily volatilised on heating. SODIUM CARBONATE, Na_2CO_3, is prepared in two ways: (1) by the Leblanc Process; (2) by the Ammonia Soda or Solway Process.—THE LEBLANC PROCESS: Common salt is heated with oil of vitriol in iron pans; sodium hydrogen sulphate and hydrochloric acid gas are produced; the acid sulphate and the unchanged salt are heated in a reverberatory furnace, and give sodium sulphate and more hydrochloric acid gas. This is called the SALT CAKE PROCESS. The hydrochloric acid gas is passed into water, and the solution is commercial hydrochloric acid. The salt cake is now mixed with powdered coal and limestone ($CaCO_3$). The coal (C) reduces the sulphate to sulphide, and the latter, with the calcium carbonate, forms sodium carbonate and calcium sulphide. This product is called BLACK ASH from its colour. The black ash is now placed in tanks, and treated with warm water, which dissolves the sodium carbonate and leaves the calcium sulphide. This solution is called TANK LIQUOR, and the solid, ALKALI WASTE. Part of the tank liquor is used in making caustic soda (*see* below), while the alkali waste is used in the manufacture of sodium thiosulphate (*q.v.*) and treated for the recovery of the sulphur (*see* CHANCE'S PROCESS). For sodium carbonate the tank liquor is treated with carbon dioxide, obtained by heating limestone, and the liquid is crystallised, giving soda crystals ($Na_2CO_3 10H_2O$); on heating, these crystals lose their water and form SODA ASH—commercial sodium carbonate.—THE AMMONIA SODA PROCESS: Strong salt solution is saturated with ammonia gas, the liquid being cooled the while. The cooled solution is forced by compressed carbon dioxide into high towers, where it meets an ascending current of carbon dioxide, which is forced into the

bottom of the tower under pressure, the outside of the tower being cooled by a stream of cold water. Sodium bicarbonate separates as a solid, and ammonium chloride remains in solution. The bicarbonate is filtered off, washed, and heated, when it yields sodium carbonate and carbonic acid. The ammonium chloride solution is heated with slaked lime, and yields ammonia, which is used in the first stage of the process. The carbon dioxide from the bicarbonate, and that which escapes from the tower, carrying some ammonia with it, are collected and utilised again. This process is very economical, as the only waste product is calcium chloride; also it yields a purer product (98 to 99 per cent. Na_2CO_3). *See also under* SODIUM. CAUSTIC SODA, NaOH, is prepared from sodium carbonate solution (or from the tank liquor of the Leblanc Process) by mixing with milk of lime ($Ca(OH)_2$) and carefully heating; calcium carbonate separates, and a dilute solution of caustic soda results. This is concentrated in iron pans till it is of the requisite strength, and is then cast in moulds. *See also under* SODIUM. POTASSIUM CARBONATE, K_2CO_3, was formerly always obtained from the ash of plants, and some is still obtained from this source. The ash is treated with water and the clear solution evaporated in pots; hence the name POTASH. In repeating this process a purer product is obtained; it is called PEARL ASH. Most of the potassium carbonate of commerce is now obtained from the potassium chloride of the Stassfurt deposits by a process exactly similar to the Leblanc Process described above. CAUSTIC POTASH (KOH) is prepared from potassium carbonate, just as caustic soda is prepared from sodium carbonate. *See also under* POTASSIUM. Sodium carbonate is used on an enormous scale in making caustic soda, in making soluble glass (cement), in making sodium bicarbonate, and other sodium compounds. Caustic soda is used in soapmaking and in refining oils. Caustic potash is used in making soft soaps.—W. H. H.

Alkali Blue. *See* DYES AND DYEING.

Alkalimetry (*Chem.*) The process of estimating the amount of alkali in a substance by adding to a measured volume of its solution a known volume of a standard acid, and using an indicator to determine the neutral point. *See* INDICATORS.

Alkaline Development (*Photo.*) Development (*q.v.*) in which an alkali is added to the solution. It is most applied to the development of dry plates containing silver bromide, the alkali helping the separation of the bromine from the metallic silver which builds up the image.

Alkaline Earths. These are LIME, BARYTA, and STRONTIA.

Alkali Waste. *See* ALKALI.

Alkaloid Reagents. Alkaloids give precipitates with: (1) Phosphomolybdic acid; (2) Phosphotungstic acid; (3) Iodine in potassium iodide; (4) Potassium mercuric iodide; (5) Potassium bismuth iodide; (6) Tannic acid; (7) Picric acid. The first three are the best and most delicate reagents. Picric acid does not give precipitates with all alkaloids.

Alkaloids are basic, nitrogen-containing ring compounds of vegetable origin; most of them are of unknown constitution, a few (conine, peperidine, nicotine, atropine) have a known constitution. Some are derivatives of pyridine, some of quinoline, and some of pyrrol. They have remarkable physiological action; most of them are optically active (lævorotatory), and some of them are among the most poisonous substances known. Besides those mentioned above, other important alkaloids are quinine, morphine, strychnine, cocaine, atropine, aconitine, veratrine, caffeine, etc.

Alkannin (*Botany*). *Alkannatinctoria* (order, *Boraginaceæ*). A red dye obtained from the root, and used in pharmacy and as a wood stain.

Alkyl. This name is given to the residue obtained by taking away one hydrogen atom from a molecule of a paraffin hydrocarbon. Thus, methane CH_4 yields the alkyl CH_3. They are not substances which can exist separately. CH_3Cl is an alkyl chloride, $(CH_3)_2Zn$ is a zinc alkyl; and so on.

Alla Breve (*Music*). In the time of a breve: four minims in a bar.

Alla Capella (*Music*). In church style: two minims in a bar, 
Allan's Link Motion (*Eng.*) A form of link motion (*q.v.*) in which a straight link is employed. In reversing, the eccentric rod is raised and the valve rod lowered by equal amounts (or *vice versâ*).

Alla Prima (*Paint.*) A painting executed without retouching. Rubens' pictures are notable examples of this method.

Allargando (*Music*). In a broad style: slackening the speed.

Allecret (*Cost.*) *See* HALECRET.

Allegory (*Art.*) A figurative representation: a symbol.

Allegretto (*Music*). Rather cheerfully: a diminutive of allegro.

Allegro (*Music*). Cheerfully, quick.

Allen's Governor (*Eng.*) A steam engine governor consisting of a fan revolving in a case filled with oil. The case can also move, but it does not do so as long as the speed of the fan is constant. When the latter varies, the case turns and acts on the regulating or throttle valve of the engine.

Allerions (*Her.*) Small birds without beaks and claws. Some hold that they are eagles which have lost beaks and claws.

Alligator Shears (*Metallurgy*). Large mechanically operated shears, with the lower blade fixed, used for cutting the bars of iron after puddling (*q.v.*) Also termed CROPPING SHEARS or CROCODILE SHEARS.

Alligator Squeezer (*Metallurgy*). A press worked on a lever principle for squeezing cinder and slag from puddled iron while still in a semi-fluid state. The name is derived from the large "teeth" or serrations on the jaws.

All Mine Pig Iron (*Metallurgy*). Ordinary pig iron, made entirely from ore, without admixture of iron-bearing slag. *See* CINDER PIG.

Allotropy. Many elements have the property of existing in more than one form. This phenomenon is called allotropy. Oxygen, O_2, exists in the *allotropic modification* ozone (O_3). Carbon exists as diamond, graphite, and charcoal. Phosphorus exists as yellow and red phosphorus. Evidently the physical properties of the allotropic modifications of an element are very different. The chemical properties are different in degree: thus, charcoal burns easily, diamond with difficulty.

Alloys. Alloys may be regarded as solid solutions of metals in metals. In some cases the metals in an alloy are in the ratio of their combining weights or multiples of these; then the alloy may be regarded as a definite compound. Alloys are produced: (1) by melting the metals together in proper proportions; (2) by electro-deposition—thus copper and zinc can be deposited together to form brass; (3) by compression of the finely divided metals. In practice metals are rarely used pure; a silver coin is an alloy of silver and copper, a gold coin of gold and silver, these alloys being harder than the pure metal.

Allspice (*Botany*). *Pimenta officinalis* (order, *Myrtaceæ*). The fruits, when nearly ripe, are dried in the sun, and form the allspice of commerce.

Alluvium (*Geol.*) Materials derived from the sub-aërial waste of upland areas are carried downhill and seawards by the action of running water. At those points where the velocity of the transporting agent, and therefore its transporting power, are checked, as where a stream reaches flat ground, or flows into a quiet pool or a lake, the materials previously carried forward by the running water are left, usually being spread out in thin layers. Accumulations thus formed soon grow up into dry land, and receive the above name.

Allyl. This is the name given to the group ($CH_2:CH.CH_2-$). $CH_2:CH.CH_2OH$ is allyl alcohol $= C_3H_5OH$. $CH_2:CH.CH_2I$ is allyl iodide $= C_3H_5I$.

Almandine (*Min.*) One of the Garnet group. It is much used in jewellery. Its colour is deep red, its hardness about 7. It crystallises in forms of the cubic system. In composition it is an iron aluminium orthosilicate. The chief localities are Ceylon (where it occurs in alluvial deposits, and *in situ* in gneiss), India, Brazil, Piedmont, etc.

Almandine Ruby (*Min.*) The violet variety of spinel (*q.v.*), cut and used as a gem.

Almayne Rivets, Almain Rivets (*Arm.*) Rivets which allowed the overlapping plates of armour to slide over one another; so called from their German origin.

Almond (*Botany*). *Prunus amygdalis* (order, *Rosaceæ*). Both the bitter and the sweet varieties yield the oil of almonds used in pharmacy.

—— (*Paint.*) An aureole, almond shaped, found in the works of early painters.

Almuce, Amess (*Cost.*) Not to be confounded with amice (*q.v.*) A fur hood or cape worn by ecclesiastics for the sake of warmth. It covered the shoulders, and hung down in front somewhat like a stole.

Aloes (*Botany*). *Aloe:* various species (order, *Liliaceæ*). This drug is prepared from the resinous juice of the leaves. Barbadoes aloes are derived from *A. vulgaris*; Socotrine aloes from *A. Perryi*; Curaçoa aloes from *A. chinensis*.

Alpaca. Wool of the Peruvian sheep or llama, of a soft lustrous fibre, used chiefly in the manufacture of dress fabrics known as alpacas.

Alps. A name originally applied solely to the upland areas of Switzerland and the mountain regions adjacent, but now extended so as to apply to any mountain tract of similar geographical character.

Al Segno (*Music*). To the sign 𝄋.

Alstonite (*Min.*) Barium calcium carbonate, $BaCO_3.CaCO_3$; barium carbonate $= 66{\cdot}3$; calcium carbonate $= 33{\cdot}7$ per cent. It crystallises in twins of the rhombic system; in appearance very like dogtooth crystals of calcite, but distinguished from calcite by the double striation on the crystal faces. From Alston Moor and Hexham.

Altar (*Archæol.*) The stand or table on which offerings to a deity were placed. In Christian times it is used to place the vessels on at the consecration of the elements. Originally of stone; now generally of wood.

Altar Cloth (*Dec.*) The covering of the Communion table or altar, often richly embroidered.

Altazimuth. An astronomical instrument for measuring the altitude and azimuth of heavenly bodies. Essentially a telescope capable of rotation round its horizontal and vertical axes, with graduated circles for measuring the angular movement in either plane. A smaller instrument on the same principle is used in surveying.

Alternate Continuous Transformers (*Elect. Eng.*) *See* ROTARY TRANSFORMERS.

Alternate Current. *See* ALTERNATING CURRENT.

Alternate Current Dynamos (*Elect. Eng.*) A dynamo without a commutator (*q.v.*) for rectifying the current, and therefore producing an alternating current (*q.v.*) *See* DYNAMOS.

Alternate Current Electro-Magnet (*Elect. Eng.*) A magnet (such as is used in alternate current arc lamps) worked by an alternating current. It must either be laminated or else built up of a bundle of iron wire, to reduce losses by induced currents.

Alternate Current Motors (*Elect. Eng.*) *See* MONOPHASE *and* POLYPHASE MOTORS.

Alternate Current Transformer (*Elect. Eng.*) *See* TRANSFORMER.

Alternating Circuit (*Elect. Eng.*) A circuit in which an alternating current (*q.v.*) is flowing. Calculations relating to these circuits must take account of their self induction (*q.v.*), and in many cases their capacity also, in addition to their resistance. The equations connecting the current and electro-motive force may be derived from Ohm's Law (*q.v.*) if we substitute impedance (*q.v.*) for resistance.

Alternating Current. An alternating current of electricity is, as its name implies, one that flows alternately in opposite directions. This does not mean that the current abruptly ceases and instantly flows in the opposite direction with the same strength. It commences at zero and rises to a maximum value, then falls to zero again and commences to flow in the opposite direction, again reaching a maximum and falling to zero; so that its value at any given instant would be represented by a wave-like curve which generally follows more or less closely the form of a "curve of sines" (*see* HARMONIC MOTION). The alternations are very rapid in most cases, about a hundred per second, and if we observe the filament of an electric incandescent lamp it appears to remain uniformly bright, just as it would if heated by a continuous current flowing steadily with a value of, roughly, three-quarters of the maximum strength of the alternating current. The special value of an alternating current is that we can take a small current with a very high voltage and transform it into a large current at low voltage by the use of a simple piece of apparatus called a transformer (*q.v.*), without any serious loss of power. As the transmission of a small current only requires the use of small wires in the mains, this method of distribution is very much

cheaper than the employment of a continuous current. For example, in lighting by incandescent lamps the voltage is about 100 volts in most cases, while the current supplied by the mains is at 2,000 volts, or twenty times as great a voltage; but the amount of current supplied by the mains in this case is only one-twentieth of the current after being transformed for use in the lamps—that is, if the mains were supplying 10 Ampères at 2,000 volts, the transformed current would give 200 Ampères at 100 volts (approximately). The chief disadvantage attending the use of alternating currents is that they are less suited for the driving of motors than continuous currents are; and when power has to be transmitted by their means, some special form of motor has to be used, and these forms can scarcely be said to have reached the same stage of efficiency which has been obtained by the continuous current motors.—G. F. G.

Altitude (*Astron.*) The angle between a star and the horizon, measured along a vertical circle.

Alto (*Music*). (1) The highest of the voices of men; also called counter-tenor. (2) The VIOLA (*q.v.* under MUSICAL INSTRUMENTS).

Alto-Relievo. Sculpture in which the figures project more than half their proper proportions from the background. *See* MEZZO-RELIEVO, BASSO-RELIEVO, CAVO-RELIEVO, *and* INTAGLIO.

Alum. Native potash alum (also called KALINITE) occurs in small quantity in the alum shales of Hurlet, near Glasgow, and at Whitby. It crystallises in octahedra of the cubic system. The composition of common alum is $K_2SO_4 . Al_2(SO_4)_3 . 24H_2O$; but a number of other alums are recognised by chemists. These have the general formula $R_2SO_4M_2(SO_4)_3 24H_2O$, where R is *one* of the metals potassium (K), sodium (Na), or the group Ammonium (NH_4), and M is *one* of the metals aluminium (Al), chromium (Cr), or iron (Fe). Common alum is potassium aluminium alum, R=K and M=Al. It is made from aluminium sulphate (obtained from shale or bauxite) and potassium chloride and sulphate. It is used as a mordant in dyeing, as an astringent in medicine, and as an adulterant to whiten bread. ALUM IN BREAD: For the purpose of enabling inferior or damaged flour to be used in the making of bread, alum, in quantities ranging from 30 to 50 grains in a 4-lb. loaf, is added. It prevents fermentation, and tends to make the bread whiter. A good rough test for detecting the presence of alum is the logwood test (*q.v.*)

Alum Bath (*Photo.*) A solution of alum, which prevents gelatine films from "frilling," or curling up at the edges, when drying.

Alumina. Oxide of aluminium (Al_2O_3), a white amorphous substance the basis of alum, and the most abundant of the "earths." It is widely diffused over the globe, and is the chief constituent of all clays, the principal ingredient in the manufacture of porcelain, and is present in more or less quantities in glass. It is used extensively in the arts, and is valuable on account of its affinity for vegetable colouring matters and animal fibres. It forms the base of certain colours in dyeing, and also acts as a mordant. *See* ALUM, ALUMINIUM COMPOUNDS, POTTERY AND PORCELAIN, BRICKS, *etc.*

Aluminium, Al. Atomic Weight, 27. This metal occurs in clay, which may be regarded as chiefly aluminium silicate; in cryolite, which is a fluorine compound ($AlF_3 3NaF$.); in bauxite $(Al . Fe)_2O_3H_2O$; in felspars and china clay. It is now always obtained by heating aluminium oxide as pure as possible in an electric furnace. The furnace is an iron vessel lined with carbon, the vessel itself forming the kathode or negative pole; the anode consists of a number of carbon rods. The charge consists of the pure oxide alone or mixed with cryolite to serve as a flux. In starting the furnace the electrodes are brought together, and then the anode is gradually raised; the arc rapidly fuses the charge, and the metal begins to separate. The process is continuous. Very pure aluminium is obtained by heating the double bromide of aluminium and sodium with pure sodium. Aluminium is a greyish-white metal which melts at 654°; it is very malleable, and its conductivity for heat and electricity is about one-third that of silver; its tensile strength is about 12 tons per square inch. The metal *when pure* is quite permanent in air; it only oxidises at a very high temperature. Hot water slowly attacks it, forming the hydrate. Hydrochloric acid dissolves it; hot, strong sulphuric acid forms the sulphate, and nitric acid has very little action. Caustic soda solution readily dissolves it, evolving hydrogen and forming sodium aluminate, $3Na_2O, Al_2O_3$. Organic acids have no action except in the presence of common salt, when there is a slight action. Of its alloys, aluminium bronze, Al (10 parts), Cu (90 parts) is the most important; it is the strongest of the copper alloys, and has the colour of gold.

Aluminium Compounds. ALUMINIUM OXIDE, Al_2O_3, occurs naturally as CORUNDUM and with ferric oxide as EMERY; ruby, sapphire, and some other gems are aluminium oxide coloured by certain metallic oxides (Cr and Co). It is obtained by heating the hydroxide or ammonia alum, as a white powder insoluble in acids. ALUMINIUM HYDROXIDE, $Al_2(OH)_6$, is formed by adding an alkali to a solution of an aluminium salt. It combines with dyes forming coloured LAKES—hence the use of aluminium salts as mordants in dyeing. ALUMINIUM CHLORIDE, Al_2Cl_6: A hygroscopic white powder, formed by heating the metal in hydrochloric acid gas and by heating a mixture of the oxide and charcoal in chlorine gas. Forms double salts with the alkali chlorides, as Al_2Cl_6NaCl. Used as a condensing agent (*q.v.*) in organic chemistry. ALUMINIUM SULPHATE, $Al_2(SO_4)_3 18H_2O$: A white powder, formed by heating bauxite with sulphuric acid. Used in paper-making, in precipitating sewage, and in making alum.

Alum Leather. Leather dressed with alum and salt, either alone, for whips, aprons, etc.; or, for gloves, with alum, salt, flour, and egg yolk.

Alumstone (*Min.*) A hydrous sulphate of aluminium and potassium, $3(Al_2SO_6) . K_2SO_4 . 6H_2O$ · alumina=37·13, potash=11·34, sulphuric acid=38·53, water=13 per cent. Usually massive and granular, sometimes in rhombohedral crystals. It occurs in acid volcanic rocks near Rome, in Tuscany, Hungary, etc. It is an important source of alum.

Alunite (*Min.*) A synonym for alumstone (*q.v.*)

Alunogene (*Min.*) A hydrous aluminium sulphate, $Al_2SO_6 . 18H_2O$: alumina=15·4, sulphuric acid=36, water 48·6 per cent. It is a product of the decomposition of shales, containing pyrites (alum shales), and is source of alum. Its crystalline system is monosymmetric, but it usually occurs in fibrous veins and incrustations near Glasgow, Hungary, North and South America.

Amadou (*Botany*). *Polyporus fomentarius* (class, *Fungi*). A spongy form of tinder, made from a fungus on old trees by soaking thin slices in saltpetre solution.

Amalgam (*Chem.*) An alloy of mercury with another metal. TIN AMALGAM was formerly used in "silvering" mirrors and on the rubbers of frictional electric machines. SODIUM AMALGAM is used as a reducing agent, as it gives a slow stream of hydrogen when placed in water. GOLD AMALGAM is used in dentistry.

—— (*Min.*) A native amalgam of silver and mercury, $AgHg_2$: mercury = 65·2, silver = 34·8 per cent. In cubic crystals of brilliant tin-white colour; brittle. From Almaden, in Spain; Dauphiné, in France; Sala, in Sweden, etc. Another amalgam with more mercury is called ARQUERITE; it is ductile; it comes from Chili.

Amalgamation Processes (*Met.*) Both gold and silver can be extracted from their ores in certain cases by the treatment of the crushed ore with metallic mercury, thus forming a SILVER or GOLD AMALGAM. *See also* GOLD *and* SILVER.

Amassette (*Paint.*) A tool used in grinding colours to gather the material together, but, like the muller, it is now obsolete.

Amateur. One who has a taste for anything, but is not a skilled workman plying his trade for a living. The term is sometimes applied to one who is only a smatterer.

Amazons. Mythical race of female soldiers often represented in art—*e.g.* the strife between Theseus and the Amazons.

Amber (*Min.*) A fossil resin of light yellow to deep brown, washed up by the sea, chiefly on the shores of the Baltic; furnishes a valuable picture varnish; also much used for beads and pipe stems. The residue left when amber is heated is used in the manufacture of some fine black varnishes. Composition: carbon = 78·96, hydrogen = 10·51, oxygen = 10·52 per cent.

Ambergris. A substance formed in the intestines of the sperm whale (*Physeter macrocephalus*). It is found floating on the sea, and is much used in perfumery.

"**Ambitty**" (*Glass Manufac.*) A term used to denote that glass has become devitrified in the pot during the time it is being worked.

Ambo. A pulpit or reading-desk in an Early Christian church.

Amboyna Wood. *See* WOODS.

Ambulant (*Her.*) The action of walking.

Ambulatory. A part of a building intended for walking in, such as the cloisters (*q.v.*)

Amentum (*Botany*). A long hanging spike of unisexual flowers, such as one sees in the hazel or poplar.

American River Steamers (*Eng.*) Large steamers of very shallow draught, often propelled by a single paddle wheel fixed at the stern; hence called "STERN WHEEL" steamers.

Amethyst (*Min.*) A violet and transparent variety of quartz (*q.v.*) used largely for cutting as an ornamental stone. Its colour is due to traces of manganese. Found in Scotland, South America, China, etc. Amethyst was supposed by the ancients to protect against drunkenness. *See also* PRECIOUS STONES.

——, **Oriental** (*Min.*) A violet variety of corundum (*q.v.*)

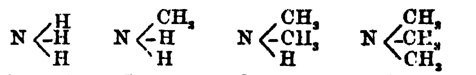
Amianthus (*Min.*) A very silky variety of asbestos (*q.v.*)

Amice (*Cost.*) "A fine piece of linen of an oblong square form, which was formerly worn on the head until the priest arrived before the altar, and then thrown upon the shoulders."—WAY. Often enriched by apparels.

Amides are compounds formed by the replacement of the hydroxyl of a carboxyl (COOH) group by the group NH_2. They are solids easily resolved into an acid and ammonia by boiling with dilute acid or alkali (*see* HYDROLYSIS). Dissolved in bromine and treated with caustic potash solution, they yield amines. Heated with phosphorus pentoxide, they yield nitriles. They are produced by heating the ammonium salts of organic acids; also by the action of ammonia on either an acid chloride (*q.v.*) or an ester (*q.v.*) For examples of amides, *see* ASPARAGINE *and* UREA, ACETAMIDE, BENZAMIDE.

Amido- *or* **Amino-.** These prefixes are employed to designate compounds formed by introducing a group NH_2 into a compound in place of a hydrogen atom—*e.g.* benzene is C_6H_6; the compound $C_6H_5NH_2$ is aminobenzene, commonly called aniline. The group NH_2 confers basic properties upon the compound formed by its introduction; thus aniline is a base. Many basic colouring matters owe their value as dyes to the presence of this group. Amino compounds have the group NH_2 replaced by OH when acted on by nitrous acids.

Amines. Compounds formed by the introduction of hydrocarbon residues into one or more molecules of ammonia in place of hydrogen. The amines are all bases like ammonia itself. *Monamines* are derived from one molecule of ammonia:



Ammonia. Primary amine. Secondary amine. Tertiary amine.

Diamines are derived from two molecules of ammonia:

A primary diamine. Ethylene diamine. A primary diamine. Phenylene diamine

Ammonia, NH_3. A colourless gas with characteristic smell; exceedingly soluble in water; it burns in oxygen, forming water and nitrogen. It is a powerful base, combining with all acids to form salts. It is used in the form of its aqueous solution. The strongest solution sold is called "880 ammonia," because its specific gravity is ·880. Ammonia is a constant product of the decomposition of nitrogenous organic matter. It is produced on the large scale from the ammoniacal liquor of the gasworks by boiling it with milk of lime.

Ammoniacal Gas Liquor. *See* GAS MANUFACTURE.

Ammoniacum. *Dorema ammoniacum* (order, *Umbelliferæ*). A medicinal gum resin which exudes from the stem of a Persian umbellifer.

Ammonia in Water. Ammonia in water in excess is taken as an index of pollution by fæcal or organic matter. Its presence either in a free state or as albuminoid ammonia is determined by quantitative analysis. For a qualitative examination Nessler's solution is added to the suspected water. If ammonia is present, the water will be coloured yellow.

Ammonia Soda Process. *See* ALKALI.

Ammonium. The name given to the group (NH_4), which is present in all ammonium salts. The group (NH_4) has no independent existence.

Ammonium Salts. AMMONIUM CHLORIDE, NH_4Cl: a white solid obtained when ammonia and hydrochloric acid are brought together: it is very soluble in water, and is used as a chemical reagent. Also called SAL AMMONIAC. AMMONIUM SULPHATE $(NH_4)_2SO_4$: formed by union of ammonia and sulphuric acid; a white solid, used as a manure. AMMONIUM CARBONATE, also called SAL VOLATILE. It is prepared by heating a mixture of ammonium sulphate and limestone. Ordinary ammonium carbonate is not a single substance, but a mixture of ammonium carbamate $CO < \begin{matrix} NH_2 \\ ONH_4 \end{matrix}$ and ammonium hydrogen carbonate $CO < \begin{matrix} OH \\ ONH_4 \end{matrix}$; when dissolved in water, it yields a solution of the latter compound. Ammonium salts are all decomposed when heated with a strong alkali such as lime or caustic soda, giving off ammonia. Most of the inorganic salts of ammonia sublime on heating.

Amœba (*Zoology*). A microscopic animal organism found in the mud of ponds and elsewhere. It is very simple in its structure, being merely a naked mass of protoplasm devoid of definite organs. Its shape is constantly changing, due to the constant flowing of the semi-fluid protoplasm.

Amorino (*generally in pl.*, **Amorini**). Cupids, often used for enrichment.

Amoroso (*Music*). Lovingly.

Amorphous. This term is applied to substances which have not a crystalline structure; *e.g.* amorphous carbon is that modification which is devoid of crystalline form—charcoal.

Amperage (*Elect. Eng.*) The amount of current which can be carried by a given conductor. It varies with the conditions of ventilation and other factors, which affect the cooling of the conductor. Tables showing the amount are given in electrical works.

Ampère (*Elect.*) The practical unit of electric current. It is one-tenth of the absolute unit (*q.v.*) Named after Ampère, a French electrician.

Ampère's Rule (*Elect.*) A rule for remembering the action of a current on a magnetic pole. If the observer swim with the current in the wire, and face the needle, then the north pole of the magnet will be deflected towards his left hand.

Ampères, Virtual (*Elect. Eng.*) *See* VIRTUAL CURRENT.

Ampère Turns (*Elect. Eng.*) The product of the number of turns in a coil and the number of Ampères flowing through it. *See* MAGNETO-MOTIVE FORCE.

Ampersand (*Typog.*) The name of the sign used for the word "and"—thus &.

Amphiantis. That form of Grecian temple which has a portico "in antis" (*q.v.*) at each end.

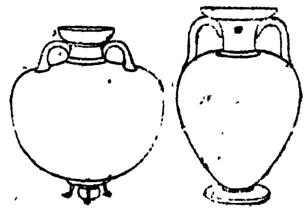
Amphibole (*Min.*) A general name applied to a section of the ferro-magnesian silicates which are allied in composition and crystalline characters to HORNBLENDE. They usually cleave in such a manner that two adjacent faces so formed give angles of about 56°. The crystallisation in tremolite, hornblende, and some other of less common occurrence is monosymmetric; in anthophyllite it is orthorhombic, while in ænigmatite it is anorthic. They are important members of the rock-forming silicates.

Amphibolite (*Geol.*) A rock consisting chiefly of one of the forms of Amphibole, usually that known as actinolite. It is generally more or less closely associated with gneiss, and is commonly one of the pegmatites of diorite gneiss. It often contains traces of some of the rarer elements.

Amphiprostyle. That form of Greek temple which has a columnar porch at each end only. *See* ANTA *and* PROSTYLE.

Amphitheatre. An elliptical or double theatre without a stage, but with a space—the arena—in the centre, and at a lower level than the first row of seats. *See* PODIUM.

Amphora. A large two-handled vessel, varying in shape, and either with or without a foot. That without a foot sometimes stood on a tripod. Amphoræ were common among the Greeks, Romans, and Egyptians, and were generally used for holding wine, oil, etc., though there are instances of their use as CINERARY URNS (*q.v.*) and even as coffins. They were generally made of earthenware; but there are numerous examples of amphoræ manufactured from more costly materials, elaborately decorated. The amphora was a standard measure with both the Greeks and Romans, among the former being equal to about 9 gallons and among the latter about 6 gallons.



AMPHORÆ.

Amplitude (*Phys.*) The amount which a vibrating body is displaced to either side from its position of rest—*e.g.* if a pendulum has a total swing of 10 in. from side to side, the amplitude, which is measured from the centre point of the path or position of rest, is 5 in.

Ampul, Ampulla. A small glass bottle, often two-handled; also the vessel containing the holy oil used in unction and in the consecration of kings.

Amulets. Charms, often of a grotesque character, still worn in some parts of the world, generally suspended from the neck. They sometimes consist of mystic words or characters, engraved on metals or stones. Such were those worn by the Early Christians.

Amygdalin. A glucoside (*q.v.*) occurring in bitter almonds and in kernels of apricots, cherries, and peaches. It is a white crystalline solid. It is resolved by the enzyme EMULSIN which is contained in almonds, and also by dilute hydrochloric acid, into glucose, prussic acid, and oil of bitter almonds:

$$\underset{\text{Amygdalin.}}{C_{20}H_{27}NO_{11}} + 2H_2O = \underset{\text{Glucose.}}{2C_6H_{12}O_6} + \underset{\text{Prussic acid.}}{HCN} + \underset{\text{Benzaldehyde (oil of bitter almonds).}}{C_6H_5CHO}$$

Amyl Acetate. A substance prepared by distilling a mixture of amyl alcohol, sulphuric acid, and sodium acetate. It is colourless, and possesses a smell like the essence of pears. Used in the preparation of collodion and other varnishes, and as a vehicle in many so-called gold paints.

Amyl Alcohol, $C_5H_{11}OH$. There are eight substances of this formula, but ordinary amyl alcohol is

a mixture of only two of them—*viz.* isobutyl carbinol $^{CH_3}_{CH_3}\!>CH\,.\,CH_2\,.\,CH_2OH$, the principal constituent, and active amyl alcohol $^{CH_3}_{C_2H_5}\!>CH\,.\,CH_2OH$. It is a peculiar-smelling liquid, and is lævorotatory. It is prepared from fusil oil by distillation, and is that fraction of the distillate which comes over about 132°.

Amyl Nitrite, $C_5H_{11}NO_2$. A pale yellow liquid smelling like peardrops. It is prepared by distilling amyl alcohol with nitric acid. When its vapour is inhaled it produces flushing of the face, and causes the heart to beat rapidly. It is used in chemistry in the preparation of diazo compounds.

Anærobic (*Botany*). The term applied to bacteria that cannot exist in the presence of oxygen.

Anaglyph (*Sculp.*) Ornament worked in low relief. *See* BAS RELIEF.

Anaglypta (*Dec.*) A relief decoration of hardened pulp formed in iron moulds. It is of great durability, and is made in a large number of artistic patterns for wall and ceiling decoration.

Analcime (*Min.*) A cubic zeolite; occurs in druses in volcanic rocks. Composition: $Al_2Si_3O_5 . Na_2SiO_3 . 2H_2O$: silica = 54·4, alumina = 23·3, soda = 14·1, water = 8·2 per cent. Found in many localities in Scotland, Giants' Causeway, Tyrol, Norway, Iceland, New Jersey, etc.

Analysis, Chemical. Is the name given to the processes employed in ascertaining the constituents of any substance. The analysis is said to be QUALITATIVE when the nature only of the constituents is ascertained, and QUANTITATIVE when the amount of the constituents is determined.

Anastatic Process (*Printing, etc.*) A method of facsimile reproduction from zinc plates, now superseded by lithography. *See* PROCESS WORK.

Anatase (*Min.*) An oxide of titanium, TiO_2: titanic acid = 98, ferric oxide = 2 per cent. (but variable). Tetragonal. Brown to deep dull blue. Cornwall and North Wales, Dauphiné in S.E. France.

Anatomy. The process and result of dissection of an organised body. Artistic anatomy comprises the knowledge of the structure and use of component parts of the human figure, more particularly the bones and muscles.

Ancaster Stone. *See* BUILDING STONES.

Anchor. A contrivance for mooring a vessel in a river or open sea; generally represented in art by the well known shape, with or without a cable. If the cable is twisted round the anchor, it is termed a foul anchor. The anchor is the emblem of hope.

Anchovy. *Engraulis encrassicholus* (family, *Clupeidæ*). A Mediterranean fish of the Herring family used as a food.

Ancon, *pl.* **Ancones** (*Architect.*) A console (*q.v.*), particularly when used to support the small cornice over a doorway.

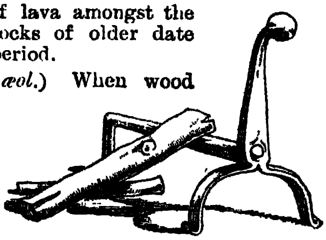
Andalusite (*Min.*) A rock-forming silicate which results from the thermo-metamorphism of rocks of argillaceous composition. It is chiefly allied to topaz, and is one of the trimorphous forms of crystallised silicate of alumina, whose other two are CYANITE and SILLIMANITE. One of its varieties is known as CHIASTOLITE. The composition of andalusite is $Al_2O_3 = 63$, $SiO_2 = 37$. Crystallisation, orthorhombic.

Andante (*Music*). "Going" at a moderate pace.

Andantino (*Music*). A diminutive of *andante*: going gently.

Andesine (*Min.*) A rock-forming silicate which constitutes one of the lime soda felspars. It is stated to be the predominating felspar in some of the lava flows of the Andes, whence the name. It is regarded as a mixture in about equal proportion of the soda, felspar albite, and the lime, soda anorthite.

Andesite. A name applied to an eruptive rock (usually a lava) which consists of a glassy or lithoidal ground mass, in which occur certain ferro-magnesian silicates, exclusive of olivine, and lime soda felspar (commonly labradorite), in larger proportion to the ferro-magnesian constituents than is the case in basalts. The composition is sub-basic, and the rocks weather with a lighter coloured crust than the basalts and their allies. It is the commonest type of lava amongst the British volcanic rocks of older date than the Tertiary period.



ANDIRON: ENGLISH, 18TH CENTURY.

Andirons (*Archæol.*) When wood was the common fuel, two iron (or other metal) supports, movable, were placed on either side of the open hearth. Against these the logs of wood leaned. Sometimes only one was used, in front, to support the spit.

Andrœcium (*Botany*). The term applied to the series of stamens in a flower.

Androsphinx (*Architect.*) A carved figure having the body of a lion and the head of a man. *See* SPHINX *and* KRIO-SPHINX.

Anelace, Anlace (*Archæol.*) A short sword or dagger, broad in the blade, sharpened both sides, and gradually narrowed from hilt to point. Seen on civilian monuments of thirteenth and fourteenth centuries. Also termed BASELARD.

Anemometer (*Meteo.*) An instrument intended for measuring the velocity of the wind. The ordinary form consists of four horizontal arms with hemispherical cups at the ends, the whole rotating on a vertical spindle, whose velocity is recorded by mechanism.

Anemophilous (*Botany*). The term describing those plants that are pollinated by means of the wind.

Aneroid (*Meteorol.*) A portable form of barometer which does not involve the use of a long column of fluid, hence it is suitable for determining the altitudes of mountains, etc. *See* BAROMETER

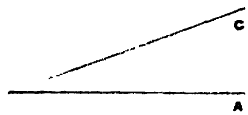
Angel Fish. *Squatina vulgaris* (family, *Squatinidæ*). A curious fish allied to the sharks and rays, formerly used as a food. The skin is used for polishing wood and also to form a fine shagreen.

Angelique. *See* WOODS.

Angiospermæ (*Botany*). One of the two great divisions of the *Phanerogamia* (flowering plants). The angiosperms are divided into monocotyledones and dicotyledones.

Angle. The degree of inclination of two lines to each other. A right angle is produced when one line meets another in such a way that the angles on both sides are equal. An acute angle is one less than a right angle; an obtuse angle is one greater than a right angle. A right angle may also be

defined as one subtended by a quadrant, or one quarter of a circle, whose centre is at the apex (or point) of the angle. In trigonometry it is often necessary to deal with angles which are greater than two right angles (180°). The definition of such angles is as follows: Let BC be a line which revolves about the point B, and originally coincided with the line BA. As BC revolves it is said to *describe* the angle ABC; thus in one revolution it will have described an angle of 360°, in two revolutions 720°, and so on.



Angle (*Lace Manufac.*) The inclination of the warp threads between the sley and the bars which gives the threads sufficient bias to keep them on the left or lower side of the hole or perforation through which they pass.

Angle Bead, *or* **Stuff Bead** (*Carp.*) A bead fixed to the external angle of a plastered wall to protect it. Modern practice is to run it in Keene's cement (*q.v. under article* CEMENTS). Also applied to a bead on an external angle in carpentry.

—— (*Plast.*) A bead run on the angle of a plastered wall.

Angle Bearing (*Eng.*) A plummer block (*q.v.*), in which the joint between the cap and main part of the block is at an angle with the base. Used when there is a thrust on the shaft which is not at right angles to the base of the block—*e.g.* in the crank shaft of an engine.

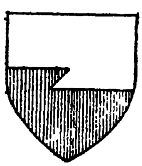
Angle Block (*Carp.*) A triangular block glued in an angle to secure two pieces together.

Angle Board (*Carp.*) A board on which wood is held in order that it may be planed with a certain angle (other than 90° or 180°) between two faces.

Angle Bracket (*Eng.*) A triangular frame of cast or wrought iron, used to stiffen the angles of a structure; in carpentry, a rough bracket fixed in the angle of a wall to support a cornice.

Angle, Critical (*Light*). *See* CRITICAL ANGLE.

Angled (*Her.*) A partition line rarely used on an English shield. The line is bent halfway and continued in a direction parallel to its original direction.



ANGLED (*Her.*)

Angle, Facial (*Art*). In tracing this the face is turned sideways, facing to right or left; a line is drawn horizontally through tip of nose, and another from the same point to front of forehead. The angle between these two lines is termed the facial angle. In antique statues the facial angle is generally about 90°.

Angle Iron (*Eng.*) A bar of wrought iron whose cross section has the form of the letter L. The angle is commonly, but not always, a right angle.

Angle of Advance (*Eng.*) The angle between the centre line of an eccentric sheave and the line which is at right angles to the crank. It causes the "lead" or opening of the port before the completion of the stroke of the piston.

Angle of Contact (*Eng.*) (1) With toothed wheels, the angle through which the wheel turns while two given teeth are in contact; (2) with belts, the angle subtended at the centre of a pulley by the part of the circumference in contact with the belt.

Angle of Contact (*Phys.*) The angle which the extreme edge of the surface of a fluid makes with a solid surface with which it is in contact. If the fluid can wet the surface (*e.g.*, water on perfectly clean glass), the angle of contact is 0°.

Angle of Deviation (*Light*). The angle between the directions of a ray before entering and after leaving a refracting medium—*i.e.* the angle through which the ray is turned or deviated by the medium.

Angle of Flexure (*Eng.*) (1) The angle through which one end of a shaft turns relatively to the other end when the shaft is subjected to torsion; (2) the angle through which any line in a body makes with its original direction when the body is subjected to torsion.

Angle of Friction (*Phys. and Eng.*) The angle at which a given plane surface must be inclined in order that a body may, when once set in motion, continue to slide upon it. In this case the force, acting on the body down the surface, equals the force of friction between the body and the plane. The tangent of the angle equals the coefficient of friction between the body and the plane surface.

Angle of Incidence (*Light*). The angle between a ray and the normal to the surface on which it is falling.

Angle of Inclination (*Eng.*) The angle which the thread of a screw makes with the axis.

Angle of Lag (*Elect. Eng.*) The difference of phase (*q.v.*) between an alternating electro-motive force and the current produced by it. The current always lags behind the E.M.F., reaching its maximum some time after the highest value of the E.M.F. has been passed. *See* POWER, ALTERNATING CURRENT.

Angle of Minimum Deviation (*Light*). The smallest angle through which a ray can be bent by a given prism. This minimum deviation is obtained when the entering and emerging rays make the same angle with the two faces of the prism.

Angle of Polarisation (*Light*). The angle at which a ray must be incident on a surface in order that the reflected ray may be polarised as completely as possible. *See* POLARISATION.

Angle of Reflection (*Light*). The angle between the reflected ray and the normal to the reflecting surface.

Angle of Refraction (*Light*). The angle between a ray after entering a refractive medium and the normal to the surface of the medium.

Angle of Relief (*Eng.*) The angle between the back edge of a tool and the material it is cutting. This angle prevents unnecessary friction between the tool and the material. It is greatest for soft materials, being between 20° and 30° for soft wood, down to 3° or 4° for hard metal.

Angle Plate (*Eng.*) A metal bracket, commonly right angled, for fixing work while being operated upon by machine tools.

Anglesite (*Min.*) Native sulphate of lead, $PbSO_4$: oxide of lead = 73·6, sulphuric acid = 26·4 per cent. It crystallises in forms of the rhombic system isomorphous with barytes, celestine, and anhydrite. It is named after Anglesea, where it was first found. It occasionally occurs massive. It is an oxidation product of galena. When in sufficient quantity, it is a valuable ore of lead. Anglesea, Cornwall, Cumberland, Dumfriesshire, Prussia, Siberia, Australia, United States.

Angle Tie (*Carp.*) A piece of timber connecting the wall plates across the angle of a building to receive the thrust of the hip rafter.

Anglo-Saxon Architecture. The name given to the architecture of England subsequent to the departure of the Romans, 449 A.D., and terminating with the Norman Conquest, 1066 A.D. The principal features of the work of this period are the belfry windows with baluster shafts, "long and short" work, triangular-headed openings, and pilaster and diagonal strips of worked stone in the rubble walls. *See* BALUSTER, "LONG AND SHORT" WORK, *and* ROMANESQUE.

Angora Goat. *Capra hircus* (family, *Bovidæ*). A variety of goat found in Asia Minor. It is valued on account of its hair, used in the manufacture of cloth.

Angular Acceleration (*Physics, etc.*) The rate of increase of angular velocity (*q.v.*)

Angular Capital. That form of Ionic capital in which a volute is placed under each angle of the abacus, and all the four faces are alike. *See* ARCHITECTURE, ORDERS OF.

Angular Diameter (*Astron.*) The angle subtended by the diameter of a heavenly body at the observer's eye.

Angular Displacement. The angle through which any given body has been turned.

Angular Distance of Stars (*Astron.*) The angle subtended at the observer by the arc of a circle drawn from one star to the other, and having its centre at the observer.

Angular Measurement. In ordinary cases this is in degrees (*q.v.*); in certain others it is given in circular measure (*q.v.*), which is better adapted to many mathematical calculations.

Angular Thread (*Eng.*) A screw thread whose section is triangular; the form most commonly used in ordinary screws.

Angular Velocity (*Physics, etc.*) The number of units of angular measurement through which an object turns in unit time. Thus, if a wheel make n revolutions per second, the angular velocity is $360n$ degrees per second, or $2\pi n$ radians per second.

Anhydride. The compound resulting when water is withdrawn from an acid. Thus, when nitric acid is distilled with phosphorus pentoxide, the latter withdraws water, and nitric anhydride results.

$$\begin{matrix} NO_2OH \\ NO_2OH \end{matrix} = \left.\begin{matrix} NO_2 \\ NO_2 \end{matrix}\right\rangle O + H_2O.$$

Anhydrite (*Min.*) An anhydrous sulphate of calcium, $CaSO_4$, $CaO = 41{\cdot}2$, $H_2SO_4 = 58{\cdot}8$ per cent., occurring in grey or white granular masses, sometimes in rhombic crystals. It is often found in association with gypsum, from which it is distinguished by its superior hardness, not scratched by the nail. Widely distributed.

Anhydrous. Without water; *e.g.* anhydrous ether means ether which has been freed from any water it might have contained.

Aniline, $C_6H_5NH_2$. A pale yellow liquid which turns red on keeping; boils at 183°; has a characteristic smell. It is a base. Slightly soluble in water. Prepared from nitrobenzene (*q.v.*) by reduction with tin (small scale), iron (on large scale), and hydrochloric acid; the product is made alkaline and distilled in steam. It gives a violet colour with bleaching powder solution, and a blue with potassium dichromate and sulphuric acid. It is used in preparing a large number of important dyes, hence the name "aniline dyes." *See* ROSANILINE, *also* DYES AND DYEING.

Aniline Dyes. *See* DYES AND DYEING.

Animal Charcoal. The product formed by distilling bones in absence of air. It only contains about 10 per cent. of carbon, the rest being calcium phosphate (80 per cent.), calcium carbonate, and other substances. Its most important property is its power of taking up colouring matter. In the sugar manufacture it is used to decolorise the syrup.

Animal Charcoal in Filters. Formerly considered an excellent medium for the filtration of water. Research has proved, however, that its use is accompanied with danger. To be efficient in their work, filters should sterilise the water—that is, they should free the water from all pathogenic organisms. Animal charcoal does not effect this; moreover, it adds to the water certain substances, phosphates and nitrates, which favour the growth and development of organisms. Its use should be discontinued in favour of the Pasteur-Chamberland or Berkefeld filter.

Animal Oils. *See* OILS.

Animal Refuse. *See* WASTE PRODUCTS.

Animals, Hybrid (*Myth.*) A compound animal made up from two or more species—*e.g.* a CENTAUR (*q.v.*)

Animation (*Art*). The touch of vivid life which a clever artist imparts to his pictures.

Animato / **Animando** } (*Music*). Animated.

Anime. A resin which exudes from a tree, called in the West Indies *Locust Tree.* It produces a fine varnish.

Anion (*Elect.*) A free atom, or group of atoms, in a solution, which travels towards the anode (*q.v.*) when the solution is subject to electrolysis. Thus, in a solution of a metallic salt, the group of elements left when the metallic element is taken away is the anion; *e.g.* in a solution of copper sulphate the anion is SO_4.

Anise. *Pimpinella anisum* (order, *Umbelliferæ*). The dried fruits form the aniseed used in pharmacy and as a flavouring agent. Oil of anise is distilled from the fruit.

Ankle Action (*Cycles*). The use of the ankle joint so that the foot acts on the pedal during a greater part of the downstroke, the pedal being, as it were, "clawed" round.

Anklet (*Archæol.*) An ankle ring of precious metal worn as an ornament by ancient races and by females of some Eastern races of the present day.

Annabergite (*Min.*) A hydrous arseniate of nickel, $Ni_3As_2O_8 . 8H_2O$. Monoclinic; occurring in capillary crystals, or as a pulverulent coating of Kupfernickel, from which it arises by decomposition; also colouring Kaolin in the proximity of nickel veins. Cornwall, Kirkcudbrightshire, Linlithgowshire, Annaberg in Saxony, the Harz, Thuringia, Sweden, etc.

Annatto. *Bixa orellana* (order. *Bixaceæ*). Annatto, or arnotto, is an orange dye obtained from the testa of the seed by soaking in water. It is used in varnishes, silk dyeing, colouring cheese and butter, etc.

Annealing. The process of strengthening a material by allowing it to cool slowly after heating. Metals, after much hammering or repeated shocks,

become brittle, and their toughness can generally be restored by annealing. Similarly glass, after being worked in a hot state, is very brittle, and requires annealing.

Annodated (*Her.*) Curved in the form of the letter S.

Annual Equation (*Astron.*) Fluctuations in the motion of the sun between perigee and apogee (*q.v.*)

Annual Rings (*Botany*). The circular marks seen in the cross section of a tree trunk, which show the amount of wood formed yearly, and also, therefore, the age of the tree.

Annular. Ring shaped.

Annular Gearing (*Eng.*) Tooth wheels, one of which has teeth on the inner side of the rim.

Annular Vault (*Building*). A vault having its abutments circular on plan.

Annulated, Annuly (*Her.*) A charge with an annulet or ring at each end,

Annulet (*Architect.*) A small fillet, the horizontal section of which is circular. There are usually from three to five annulets under the echinus or ovolo of a Doric capital. *See* DORIC *and* COLUMN.

—— (*Building*). A ring or fillet round a column.

—— (*Her.*) A plain ring which occurs as a charge, or on the shield of the fifth son as a mark of difference.

Anode (*Elect.*) The conductor or electrode by which a current enters a liquid.

Anomalistic Year (*Astron.*) The period of the revolution of the sun from perigee to perigee again.

Anorthic (*Min.*) One of the crystallographic systems (*q.v.*) in which there are three axes, all unequal and all inclined to one another at the origin at an angle other than a right angle Also called the Triclinic system. It has no plane of symmetry.

Anorthite (*Min.*) A somewhat rare rock-forming silicate, constituting a lime felspar. The chief mode of occurrence is that of one of the constituents (along with albite) of the intermediate types of the Plagioclase felspars. It occasionally occurs as a separate mineral, most generally in connection with the blocks of metamorphosed limestone formerly ejected from Vesuvius, and now to be obtained on Monte Somma.

Answer (*Music*). The response to the subject of a fugue.

Anta, *pl.* **Antæ** (*Architect.*) A pilaster used in Greek and Roman architecture as a finish to the side wall of a temple when it projected beyond the end wall. The capital and base of a Greek anta were always different from those of the columns used in conjunction with it. A temple is said to be "IN ANTIS" when its porch is formed by the projection of the side walls with two or more columns between them. This differs from a "PROSTYLE" temple, as in the latter the columns are placed in front of the antæ. *See* CELL, AMPHIANTIS, AMPHIPROSTYLE, PROSTYLE, *and* DISTYLE.

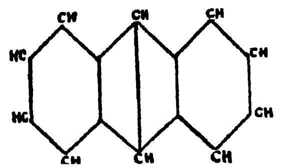
Antarctic Circle (*Astron.*) *See* ARCTIC CIRCLE.

Antefixæ (*Architect.*) Ornamental blocks, either of marble or terra-cotta, fixed along the eaves of a Greek building to cover the joints of the tiles.

Antependium (*Dec.*) Literally, anything hanging before the altar, now termed the frontal; generally an embroidered cloth.

Anthemion (*Architect.*) The honeysuckle ornament as used in Greek architecture, principally as an enrichment on a cyma-recta (*q.v.*)

Anthracene. Obtained from that part of coal tar which distils above 270°—"anthracene oil"—by a process too elaborate to be given here. It can be obtained synthetically—*e.g.* from benzene, acetylene tetrabromide, $C_2H_2Br_4$, and aluminium chloride. It is a white



ANTHRACENE.

crystalline solid, showing a blue fluorescence; melts at 213°. It is the parent substance of a large number of important dyes (*see* ANTHRAQUINONE *and* ALIZARIN). *See also* GAS MANUFACTURE, *and* DYES AND DYEING.

Anthracite. Hard coal, very rich in carbon, burning with an intense heat and little smoke; much used in steamships. *See also* COAL.

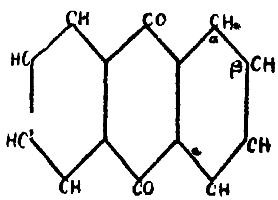
Anthranilic Acid (*O-amidobenzoic acid*),

$$C_6H_4 <^{COOH}_{NH_2} \ (1:2).$$

A white crystalline solid which melts at 145°; sweet taste. Obtained from indigo by the action of caustic potash. Used in the synthesis of acridine and quinoline derivatives, and now especially in the preparation of pure artificial indigo, for which purpose it is obtained cheaply from naphthalene (*q.v.*) *See also* PHTHALIC ACID *and* INDIGO.

Anthrapurpurin. *See* DYES AND DYEING.

Anthraquinone Crystallises in yellow needles which melt at 285°; it is produced by oxidising anthracene with chromic acid. Anthracene is formed from it by heating with zinc dust and ammonia. When anthracene is heated with fuming sulphuric acid, it gives β-anthraquinone sulphonic acid



—that is, the group SO_2OH replaces the H at β in the above formula. *See* ALIZARIN.

Anthropomorphism (*Myth.*) The representation of a god in the form of a man or woman.

Antichlor (*Chem.*) A substance used for removing the last traces of chlorine from materials which have been bleached by its means. The sodium sulphites and sodium thiosulphate are used as antichlors.

Anticlinal (*Geol.*) The sedimentary rocks composing the earth's crust have usually been deposited in horizontal layers piled one upon another. In some cases these have been left undisturbed, but in others the pile has been subjected to lateral thrusts which have bent the rocks into folds. It is convenient to distinguish these as downfolds or synclinals, and upfolds or anticlinals

Anticyclone (*Meteor.*) An area of high atmospheric pressure—*i.e.* one over which the barometer is high. Round this area the winds, observed from above, appear to be blowing in a clockwise direction.

Antifebrin. *See* ACETANILIDE.

Anti-Fouling Compositions. Substances used to prevent marine growths on the bottoms of ships.

They are very numerous; one is composed of zinc dust and mercuric oxide made into a paint.—HANNAY.

Anti-Friction Bearings (*Eng.*) The bearing or support of an axle in which friction is diminished by allowing the axle to rest on wheels, rollers, or spherical balls which can revolve. The ball bearings of cycles are a common example. *See* CYCLES.

Anti-Incrustators (*Eng.*) Substances used to prevent the formation of scale in boilers. Paraffin oil, peat, potatoes, and many other substances serve the purpose.

Antimonite (*Min.*) A synonym for STIBNITE (*q.v.*)

Antimony. This element occurs native as a tin white to dark grey lamellated or mammillated mineral; very brittle. It occurs in combination in Stibnite, Jamesonite, Boumonite, Kermesite, Valentinite, Senarmontite, etc. (*q.v.*) It occurs native at Allemont in France, in the Harz, in Bohemia, Sweden, Borneo, Canada, New York, etc. It is a metal of atomic weight 120, crystalline, brittle, easily oxidised; unacted on by hydrochloric acid. Hot strong sulphuric acid forms the sulphate $Sb_2(SO_4)_3$ and sulphur dioxide; nitric acid forms the pentoxide Sb_2O_5. The metal is obtained by heating the naturally occurring sulphide (stibnite) with iron and refining the product. It is used in making a number of alloys—*e.g.* type metal lead, 70; antimony, 18; tin, 10; copper, 2.

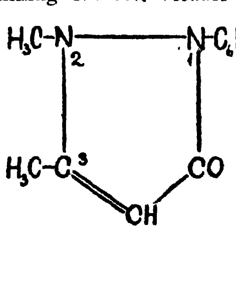
Antimony Compounds. OXIDES, Sb_2O_3, Sb_2O_4, Sb_2O_5. The trioxide Sb_2O_3, best prepared by adding water to solution of the trichloride and thorough washing of the precipitate of oxychloride, is used in making tartar emetic. Sb_2O_4 is formed when either of the other oxides is heated in air. Sb_2O_5 (*see* ANTIMONY). TRICHLORIDE, $SbCl_3$, formed by heating the sulphide with strong hydrochloric acid and evaporating to dryness, is a soft solid known as "butter of antimony"; mixed with olive oil, it is used in "bronzing" articles such as gun barrels. PENTACHLORIDE, $SbCl_5$, a liquid obtained by action of chlorine on antimony, serves as a chlorine carrier. SULPHIDE, Sb_2S_3: the natural variety is black and crystalline; the artificial variety, formed by passing sulphuretted hydrogen into solution of the chloride, is orange and amorphous; soluble in hot strong hydrochloric acid, forming the trichloride and sulphuretted hydrogen; soluble in alkalis and alkaline sulphides. Used in making safety matches and in pyrotechny.

Antimony Glance (*Min.*) A synonym for STIBNITE (*q.v.*)

Antiplastic (*Pot.*) Anything added to paste—*i.e.* prepared clay—to reduce its plasticity.

Anti-Priming Pipe (*Eng.*) A pipe which collects the steam from the top of a boiler and conveys it to the engine. It has a closed end, which is pierced with small holes; the object is to prevent fine spray (drops of water) from being carried over into the cylinder.

Antipyrine. Forms shining leaflets, soluble in water and alcohol; melts at 114°; a monacid base. Formed by heating the product of the reaction between ethylacetoacetate (*q.v.*) and phenylhydrazine (*q.v.*) with methyl iodide. Used in medicine as an antipyretic (lowering the temperature); it depresses the heart.



Antiquaille (*French*). Contemptuous term for antiquities of little importance.

Antiquarian. The name given to drawing-paper of size 53 × 31 in.

Antiquary. One who is devoted to archæology (*q.v.*), now generally termed an archæologist. Also applied to a dealer in curiosities.

Antique. In art, applied to ancient Greek and Roman works of art, especially those of the best and purest style. A course of drawing from the *antique* generally precedes drawing from the living model. A dealer in antiques is one who sells smaller relics of antiquity, as gems, etc.

—— (*Typog.*) Type in which all the lines of the face are of uniform thickness.

Antiquities. Remains or relics of ancient times, including monuments, arms, ornaments, customs, etc.

Antiseptics. Substances which prevent or arrest putrefaction by stopping the growth or destroying the organisms which induce it. Some of the most important are: mercuric chloride (1 in 1,000), carbolic acid, iodoform, chlorine, hypochlorous acid, boric acid, creosote, formaldehyde, etc. Antiseptics are frequently added to foods and to many organic materials used in the arts, *e.g.* size, for preventing mildew.

Anti-Syphonage Pipe (*Plumb.*) A pipe fixed to the top of traps to prevent the water seal (*q.v.*) being sucked out.

Anvil. The heavy block of wrought iron faced with hard steel on which metal work is hammered. Anvils range from the size used by watchmakers up to the huge masses, built up of many pieces, which form the support for forgings under the steam hammer. The name is also applied to parts of various machines.

Anvil Cutter *or* **Chisel** (*Eng.*) A short chisel, fixed by a shank into a hole in the anvil, across which a bar can be laid and cut by blows on the upper surface.

Aorta (*Biology*). The main arterial trunk given off from the heart.

A.P. (*Typog.*) These letters stand for "author's proof."

Apatite (*Min.*) A phosphate and chloride of calcium occurring in various shades of grey, green, and blue, granular or crystallised in hexagonal prisms. Composition: $3(Ca_3P_2O_8) . CaCl_2$.; lime = 48·43, phosphoric acid = 40·92, calcium chloride = 10·65 per cent. In some varieties fluorine replaces the chlorine. From Spain, Cornwall, Cumberland, United States, etc. COPROLITE is an impure variety of organic origin.

Aperture (*Photo.*) The area of the "stop" or opening through which the beam of light produced by the lens must pass. Decreasing the aperture diminishes the amount of light falling on the plate, and increases the time of exposure necessary, but it makes the image more sharp.

Apex. (1) The point or corner of a geometrical figure; (2) the summit of an object; (3) in mining, the part of a mineral vein which is nearest to the surface of the ground.

Apex Stone (*Building*). The stone at the top of a gable.

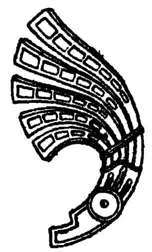
Aphelion (*Astron.*) The position of the earth when farthest from the sun—*i.e.* when the sun is at apogee. This occurs on the 1st of July. When the earth is nearest to the sun it is said to be in PERHELION, and the sun is said to be in PERIGEE. The diameter of the earth's orbit drawn between these two positions is termed the APSE LINE.

A Piacere (*Music*). At pleasure.

Aplite *or* **Haplite** (*Geol.*) A term now applied to a rock of eruptive origin which has been formed at a late period in the consolidation of an eruptive mass, usually one of plutonic origin. It represents the products of the magma, which were the last to consolidate, and which have filled cracks or other divisional planes in the cooling and contracting mass. Its constituents, in all cases, are of more acid composition than the mass in which it occurs. As examples, granite aplite, syenite aplite, diorite aplite, galbro aplite, etc.

Aplome (*Min.*) An iron calcium orthosilicate, one of the Garnet group. It is cubic, of deep brown, yellowish, or yellow green colour; hardness more than 7. Localities are the River Lena in Siberia, Ala in Piedmont, and Schwarzenberg in Saxony.

Aplustre. The stern of Greek and Roman galleys was continued upwards and shaped into an ornament so called. Used as an emblem of victory.



APLUSTRE.

A Poco a Poco (*Music*). By degrees.

Apogee (*Astron.*) The position of the sun, relative to the earth, when the distance between them has its greatest value. *See also* APSE.

Apollinaris Water. An alkaline spring water containing a large amount of sodium bicarbonate and smaller amounts of sodium chloride, potassium sulphate, and the bicarbonates of magnesium, calcium, and iron; it also contains dissolved carbonic acid.

Apollo. In Greek and Roman mythology the son of Zeus (Jupiter) and Leto (Latona). APOLLO BELVIDERE, a statue of Apollo in the Belvidere Gallery at the Vatican, esteemed one of the finest representations of the human figure extant.

Apophyge (*Architect.*) That part of a column between the cylindrical part of the shaft and the fillet of the base or of the necking. It is usually a cavetto, and is also known as the CONGÉ. *See* COLUMN.

Apophyllite (*Min.*) A tetragonal zeolite, colourless to greyish, often transparent. Composition: $K_2O . 8CaO . 16SiO_2 . 16H_2O$: silica = 55·5, lime = 23, potash = 4·8, water = 16·7 per cent. It often occurs in volcanic rocks with stilbite and other zeolites. Near Edinburgh, Talisku, Old Kilpatrick, Raith, in India at the Boorghat railway cutting, Greenland, Iceland, Norway, and Sweden.

Apostrophe (*Typog.*) The sign which marks the omission of a letter or letters; thus, *ne'er* for *never*; *can't* for *cannot*. In modern English it also indicates the possessive (genitive) case, *e.g.* the *boy's* hat.

Apotheosis. Elevation of a mortal to divine rank. In the case of Roman emperors this was effected by burning an effigy of the deceased; and as the fire ascended, an eagle was let loose, which was supposed to bear the soul aloft. There are in existence numerous representations of the ceremony in the form of medals, etc.

Apparels (*Cost.*) Richly embroidered cloth sewn on to the wrists of the alb and on the front and back of the lower edge; also on the amice. By some these five were considered to represent the five wounds of Christ. *See* ALB; AMICE.

Appassionata (*Music*). Impassioned.

Appaumée (*Her.*) The open hand with palm exposed to view.

Appearing (*Typog.*) A term used to express the length of the printed matter on a page, exclusive of whiteline.

Apple (*Botany*). *Prunus malus* (order, *Rosaceæ*). The well known fruit. In addition to its use for eating purposes, cider is made extensively from it in the west of England, Normandy, etc. In mythology, the Golden Apple, Apple of Discord, and other metaphorical references to the apple occur.

Apple Wood. *See* WOODS.

Appliqué. Ornament laid on or let into material; used of metal, wood, or textile fabrics.

Appoggiatura (*Music*). A leaning note. In performance it takes its value from the principal note which it adorns—*viz.* one half—unless the principal note is dotted, when it takes two-thirds of the value.

Approximation. A result or "answer" of some calculation or measurement which, though not actually correct, is near enough for the purpose required. Of great value in checking the correctness of a calculation.

Apricot. *Prunus armeniaca* (order, *Rosaceæ*). The tree is cultivated for its fruit. The liqueur *Eau de noyeaux* is distilled from the seeds.

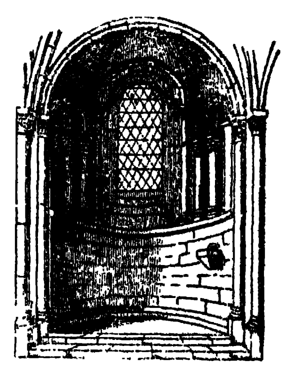
Apron (*Carp.*) A flat lining or covering used to protect parts of the structure underneath, especially the inside woodwork under a window.

—— (*Eng.*) The vertical front part of a screw-cutting slide rest; also applied to other machine tools.

—— (*Paper Manufac.*) A flexible rubber cloth used for guiding the pulp on to the machine wire.

—— (*Plumb.*) The horizontal flashing (*q.v.*) of a dormer, etc.

Apse (*Architect.*) A projecting portion of a building, semicircular or polygonal in plan; particularly applied to such a projection forming a termination to the choir, aisle, transept, or nave of a church. *See* BASILICA.



APSE, ROMSEY CHURCH, HANTS.

—— (*Astron.*) The points on the sun's orbit at which it is either nearest to the earth (perigee) or farthest away (apogee). The line joining the two apses is called the Apse Line.

Apse Line (*Astron.*) *See* APSE (*Astron.*)

A Punta d'Arco (*Music*). With the point of the bow.

Aquæ Manalis. The basin or dish in which the priest washes his fingers at celebration.

Aqua Fortis. Weak nitric acid used by etchers. The name was once universally used by chemists for nitric acid, whether dilute or not.

Aquamarine (*Min.*) The pale blue green variety of BERYL (*q.v.*) Aquamarine is cut as a gem.

Aqua Regia. A mixture of 3 volumes of hydrochloric acid and 1 volume of nitric acid. The mixture gives off chlorine and another gas called nitrosyl chloride, thus: $HNO_3 + 3HCl = 2H_2O + NOCl + Cl_2$. Called aqua regia by the alchemists because of its power of dissolving gold; the solution of the gold is effected by the chlorine which forms chloride of gold, a substance very soluble in water.

Aquarelle (*Paint.*) A painting executed with Chinese ink and very thin water colours.

Aquatint. *See* ENGRAVING *and* ETCHING.

Aqueduct. A conduit for conveying water from one place to another, extensively used by the Romans. Many of them still remain on the Continent, such as that at Segovia in Spain. The Claudian aqueduct, built A.D. 50, can still be traced. Ancient aqueducts were open at the top, and were built at a uniform gradient or slope, hence they were carried over valleys on lofty arches.

Aqueous Rocks. Rocks which have been formed by the direct action of water, as distinguished from rocks due to volcanic action, to the action of ice, to that of the wind, or to plutonic causes.

Arabesque. Ornament consisting of foliage, fanciful figures, flowers, fruit, etc., formed into scrollwork in flowing lines, either painted, inlaid, or executed in low relief. In Moorish arabesque or *Moresque* no animated life is depicted, being prohibited by their religion; but in the Renaissance work the human figure (or portions of the human figure), as well as animals, are introduced. Raphael's arabesques on the loggia of the Vatican are notable examples of the combination of allegory with ornament.

ARABESQUE, FROM ITALIAN MAJOLICA.

Arabinose, $CH_2OH \cdot CHOH \cdot CHOH \cdot CHOH \cdot CHO$. A sugar obtained by treating gum arabic or cherry tree gum with dilute sulphuric acid. It is crystalline, melts at 160°, and is dextrorotatory; not fermented by yeast. In other respects its reactions are like those of a sugar.

Aræostyle (*Architect.*) The name given to the spacing of columns in a Grecian temple when the space between the columns is equal to three and a half times the lower diameter of the shaft. *See* PYCNOSTYLE, SYSTYLE, EUSTYLE, DIASTYLE, *and* INTERCOLUMNIATION.

Aragonite (*Min.*) Calcium carbonate in the rhombic form (*see* CALCITE). Occurs in crystals, often twinned, and in fibrous and massive forms. Colour, when pure, white, but often coloured grey or green. Distinguished from calcite by its superior hardness and lack of cleavage. Composition: lime = 56, carbonic acid = 44 per cent. Occurs often in association with iron ores, also in vapour cavities in lavas.

Arbalest, Arbalist, Arblast; *also* **Arcubalist.** From the Latin *arcus*, bow, and *ballista*, an engine for throwing. A crossbow, especially those with mechanism for drawing the bowstring.

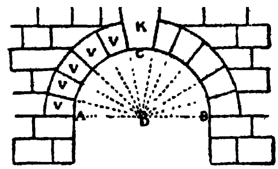
Arbor. The cylindrical axis of various parts of a timepiece — as BARREL ARBOR, FUSEE ARBOR, CENTRE ARBOR, etc.

Arbroath Flags. The grey micaceous flags which underlie the volcanic rocks of the Sidlaw Hills, and which form part of the lower division of the Caledonian (or "Lower") Old Red Sandstone. They are largely quarried for paving stones as well as for building purposes. It is mainly in this sub-division of the Scottish rocks of Devonian age that the remains of Pterygotus and of other allied Eurypterids have been found. Its relations to the rocks next beneath are not seen.

Arc. A part of the circumference of a circle; more generally a part of any curve.

Arcade (*Architect.*) A series of arches springing from pillars or columns, and used either for structural purposes or as a decorative treatment of a wall surface.

Arch. A curved structure built of separate blocks carrying the weight of a portion of a building over an open space. It therefore serves the same purpose as a beam (*q.v.*), but it does not require the use of one large piece of material the full width of the opening or span, and is consequently adapted to pure masonry work. The terms used with respect to arches will be readily understood by a reference to figure, which shows an elevation of one of the simplest forms, the semicircular arch. The line AB is termed the SPRINGING LINE, and its length the SPAN. The point C is the CROWN or VERTEX, and the height CD is the RISE. The inner curved line ACB is the INTRADOS, the outer curved line the EXTRADOS. The separate stones V, V are the VOUSSOIRS, the central stone K being termed the KEYSTONE, and the lowest ones at A and B the "SPRINGERS." The masonry which supports the arch on the two sides has various names; when it consists of vertical columns, the latter are called PIERS; if they have to resist an oblique thrust, as in most bridges, they are usually termed ABUTMENTS; if the arch rests on simple vertical walls, they are termed BEARING WALLS. The two halves AC and BC are termed the FLANKS or HAUNCHES. Besides being made in the form of an arc of a circle, arches are also built to various curves, such as the ellipse, parabola, hyperbola, and catenary; and they are also made with a pointed top for decorative purposes where great strength is not necessary. Among the latter are the Horseshoe Arch (Arabian work), Pointed (Middle Ages), Lancet (Gothic and Early English), Equilateral (Decorated), Ogee (Later Decorated), Segmental and Tudor (Debased Gothic). From the constructional point of view, arches are also classified as PLAIN, when made of unaltered bricks; GAUGED, when the bricks are accurately cut or rubbed to form the voussoirs; AXED or ROUGH ARCHES, when the bricks are roughly cut to the shape required. A SKEW ARCH is one which crosses a road, etc., at an angle: its plan is a rhombus or rhomboid, and the abutments must be cut stepwise to take the oblique thrust.



SEMICIRCULAR ARCH.

Archæan Rocks (*Geol.*) A term usually applied to the whole of the vast assemblage of rocks which are older than those of Cambrian age. It includes

the Lewisian gneiss and the ancient sediments associated with that complex mass. It probably includes also the greater part of the metamorphic schists which form the Scottish Highlands. The Archæan rocks of Britain are too varied in character to be adequately described in a short paragraph. The chief common characteristic lies in the fact that most of their structures are due to dynamic causes.

Archæology. The systematic study of all that appertains to past times, especially the remains and monuments of the prehistoric period.

Archaic. Pertaining to archaism.

Archaism. An imitation of what is old or obsolete, consequently out of character with its modern surroundings.

Archimedean Drill (*Eng.*) A small drill whose stock consists of a coarse screw thread, carrying a nut. By sliding the nut up and down, an alternating rotary motion is given to the drill. The drill must therefore be specially ground.

Archimedes' Principle (*Physics*). A solid immersed in a fluid experiences an upward force equal to the weight of the fluid displaced; the solid therefore appears to lose weight to an amount exactly equal to the weight of its own volume of the fluid.

Architectural Work in Photography. A lens is used which gives all lines as straight as possible; this requires some form of "doublet" lens (*q.v.*)

Architecture. The art of designing and constructing useful and beautiful buildings. It is generally divided into CIVIL (dealing with houses, bridges, and other buildings of ordinary utility), ECCLESIASTICAL (churches), NAVAL (ships), MILITARY (fortifications).

Architecture, Orders of. An architectural composition consisting of a column, with or without a pedestal, and with an entablature, is known as an order. Each of these three divisions of an order is again divided into three parts: the pedestal, consisting of a base, a die or dado, and a cornice or surbase; the column, of a base (excepting in the case of the Greek Doric), shaft, and capital; and the entablature, of an architrave, frieze, and cornice. There are three Grecian orders: the Doric, the Ionic, and the Corinthian. The Romans used these orders with various modifications, and also two varieties of the Doric and Corinthian, known as Tuscan and Composite respectively. Pedestals were introduced by the Romans with the object of increasing the total height of the order without altering the other dimensions (*see* GREEK ARCHITECTURE, ROMAN ARCHITECTURE, *and* PEDESTAL).—THE DORIC ORDER (*see illustration under* DORIC) is the earliest and most severe of the orders used by the Greeks. The chief buildings in which it is used are the Temple of Corinth (B.C. 650), the Temple of Theseus at Athens (B.C. 465), the Parthenon at Athens (B.C. 438), and the Propylœa at Athens (B.C. 437-2). The latter is partly Doric and partly Ionic. The column has no base, the shaft resting directly on the stylobate (*q.v.*) The shaft usually has twenty elliptical flutes meeting in arrises, and is worked to a very slight ENTASIS, the curvature in the case of the Parthenon shafts being about half an inch in a length of 31 ft. The upper diameter of the shaft is about four-fifths of the lower diameter. The height of the column varies from 4½ to 7, but is usually 6 times the lower diameter; the columns of the Parthenon are 5½ diameters in height. The capital is one of the most beautiful features of the order. Its height is usually equal to about half a lower diameter, and it consists of a neck separated from the shaft by a fine groove, a delicately moulded echinus with three to five fine armulets, and a perfectly plain abacus (*see illustration under* ABACUS). The height of the entablature is equal to about twice the lower diameter of the shaft, the cornice being about two-thirds the height of either the architrave or the frieze, and its projection being equal to about 1 module or half a lower diameter. The frieze is the most striking division of the entablature, consisting of square panels or metopes (*q.v.*) frequently carved, separated by the triglyphs, which are the constructive parts of the frieze. The face of each triglyph shows two vertical grooves and two chamfers or half grooves at the edges, the stop of the grooves at the top being usually curved (*see* TRIGLYPH). The band over the triglyph, known as its capital, has a much slighter projection than in the Roman examples. A triglyph occurs over each column with the exception of the end one, the triglyph in this case being placed at the end of the frieze. There is usually one triglyph over the space between any two columns, but occasionally the intercolumniation is increased so as to allow of two triglyphs in this position. Although the end triglyph is not placed over the centre of the end column, the two metopes nearest the end of the frieze are little, if any, larger than the others, as the end intercolumniation is reduced. The architrave projects slightly beyond the face of the shaft, and is very plain, having merely a tenia on its upper edge and a row of guttæ under each triglyph. It should be noted that the fillet over the guttæ and under the tenia, known as the capital of the guttæ, is rather deep, and that the guttæ are very short, the reverse being the case in Roman examples (*for illustration, see under* GUTTÆ). The cornice consists of a corona, on the sloping soffit of which is a series of mutules (*q.v.*), each mutule having three rows of guttæ on its underside, and a simple bed moulding. The crowning member of the cornice is usually an ovolo. In the Doric order of the Parthenon great care was taken to counteract optical illusions. The entasis of the shafts is just sufficient to prevent the appearance of hollowness which would be given by a simple conical form. An appearance of strength is imparted to the angles by reducing the end intercolumniation, and for similar reasons all the columns lean slightly inwards, and the stylobate and entablature are slightly raised in the centre. It should be noted that the effect of Greek Doric temples depended to a considerable extent on the colour decoration of their various parts.—THE ROMAN DORIC ORDER (*see illustration under* COLUMN) varies very considerably from that used by the Greeks. The column is usually 8 diameters in height, and has a base generally 1 module in height. The shaft is frequently not fluted, and its upper diameter is four-fifths or five-sixths the lower diameter. When the shaft is fluted, the flutes are semicircular in plan, and are separated by fillets. The capital is much less refined than that of the Greek Doric order. The necking consists of an astragal with a fillet and congé under, instead of the groove in the Greek Doric. The ovolo of the capital is a quarter circle, the annulets are rectangular fillets, and the abacus is crowned with a cymatium. The entablature (*q.v.*), like that of the Greek Doric, is 2 diameters in height, but the height of the architrave is reduced to about 1 module, the frieze—about 1½ modules in height—being made the largest member of the

entablature. The architrave does not project beyond the face of the shaft, but is in the same face as the neck of the capital. The end triglyph is always placed over the centre of the end column; the stop at the top of each groove or glyph is angular; the capital of the triglyph has a larger projection than in the Greek order; the guttæ on the architrave are longer than the Greek guttæ, but the capital of the guttæ is reduced in depth. Mutules are never used over the metopes, and are sometimes omitted altogether, and a dentil course substituted. The crowning member of the cornice is either a cavetto or a cyma-recta, instead of the ovolo used in the Greek Doric order.—THE GREEK IONIC ORDER (*see illustration under* IONIC *and* VOLUTE) is the second one used by the Greeks. Its proportions are more slender than those of the Greek Doric, and the mouldings are profusely enriched, carving taking the place of the colour decoration used with the Doric. The principal buildings in which it occurs are: The Temple on the Ilissus at Athens (B.C. 484); the Temple of Niké-Apteros at Athens (B.C. 469); the Propylæa at Athens – internal columns (B.C. 437-2); the Temple of Apollo Epicurius at Phigalæa—internal columns (B.C. 430); the Erectheum at Athens (B.C. 479-08); the Temple of Diana at Ephesus (B.C. 330); the Temple of Minerva Polias at Priene (B.C. 320). The details of the various Greek examples of the Ionic order vary much more than those of the Doric, but the following notes are of general application. The column consists of a shaft having twenty-four flutes, separated by fillets and descending into the congé; a base, usually richly moulded and generally of the Attic form, sometimes with and sometimes without a plinth; and a voluted capital. This capital consists of an enriched bead and echinus, both circular on plan, with a cushion-like feature above, the front and back faces of which are parallel to the wall of the temple. Each of these faces consists of a band terminating at each end in a volute. The projection of the echinus in front of this band is one of the two weak points in the design, the other being the difficulty which arises in the capital of a column at the angle of a building, the angle capital having a double face and the volute between the two faces being arranged at an angle of 45°. The abacus is much thinner than that used in the Doric order, and, unlike the latter, is moulded. The column varies from 8 to 9 diameters in height, the latter figure being the most usual proportion. The heights of the base and capital are about threequarters of a module and 1¼ modules respectively; the top diameter of the shaft is about 1⅝ modules. The entablature is generally 2 diameters in height, and the three divisions of it are about equal. The architrave usually has three fascias, each of the upper two of which projects slightly beyond the one beneath it, and is finished with a delicate cymatium. The frieze is either quite plain or is sculptured in relief. The cornice usually has a dentil course below the corona, and the latter is generally finished with an enriched cyma-recta.—THE ROMAN IONIC ORDER: There is not so much difference between the Greek and Roman examples of this as there is between those of the Doric and Corinthian orders. Like the Doric order, however, it was little used by the Romans. In the Roman Ionic order the column is 9 diameters in height, the shaft being either plain or fluted. The base is usually of the Attic form, and always has a plinth. The capital is often made with angle volutes, the four faces being similar, and the abacus concave on plan. When this is done, the scrolls spring out of the echinus, and do not form an integral part of the capital, as in the Greek order. The entablature does not differ much from that of the Greek Ionic, with the exception, of course, of the detail of the mouldings and their enrichments.—THE GREEK CORINTHIAN ORDER: The Corinthian order was little used by the Greeks, the principal examples being the Choragic monument of Lysicrates at Athens (B.C. 335) and the Tower of the Winds at Athens (B.C. 100-35). The shaft and base are only slightly different from those used in the Greek Ionic order, but the shaft is generally 10 diameters in height. The Corinthian order at the Tower of the Winds has no base, and there is no plinth to the base of the other example mentioned. The capital is again the most distinctive feature of the order, and in the case of the Choragic monument of Lysicrates is 1½ diameters in height, and consists of a bell-shaped core, the lower part of which is clothed with a conventional treatment of the acanthus leaf, the upper part having a small volute at each of the four angles with honeysuckle ornament between, and a moulded abacus with concave faces.—THE ROMAN CORINTHIAN ORDER (*see illustration under* CORINTHIAN). The Corinthian order was more fully developed by the Romans, and was the one principally used by them. The column varies from 9½ to 10½ diameters in height, and generally has a base resembling the Attic. The shaft is generally fluted, but sometimes the upper part is fluted and the lower part plain. The capital, about 1⅙ diameters in height, is richly carved, even the mouldings of the abacus being enriched in some cases. It consists of two tiers of acanthus leaves at the base of the bell, four pairs of large volutes supporting the angle of the abacus, and four pairs of small volutes under the flowers or "roses" in the centres of the concave faces of the abacus. The entablature is about 2½ diameters in height, the heights of the frieze and architrave being about equal, and each rather less than the height of the cornice. The principal feature of the entablature is the use of modillions above the dentil course to support the corona of the cornice. These modillions, and almost all of the mouldings of the entablature, are richly carved. The projection of the cornice is about equal to its height. The frieze is frequently quite plain, but the architrave, which consists of three fascias and a crowning moulding, is usually enriched.—THE TUSCAN ORDER (*for illustration, see* TUSCAN) is a Roman modification of the Doric order. It is the simplest of the orders used by the Romans, being always used without enrichment. The column is usually 6 diameters in height. The capital is similar to the Roman Doric, but the abacus has merely a fillet at its upper edge in lieu of the moulded Doric cymatium; the shaft is never fluted, and the base consists of a fillet, a torus, and a plinth. The entablature is rather less than 2 diameters in height, and is perfectly plain, having neither triglyphs, mutules, dentils, nor modillions. The crowning moulding of the architrave is simply a small cavetto and a fillet.—THE COMPOSITE ORDER (*for illustration, see* COMPOSITE) is a modification of the Corinthian order, and was not used by the Greeks. The chief alteration is in the capital, the upper part of which is similar to the Roman Ionic capital, with angle volutes, while the lower is very similar to that of the Roman Corinthian capital. The general proportions are the same as those of the Roman Corinthian order. The term ORDERS is also used to denote the recesses or groups of buildings in a Gothic or Romanesque arch.—W. S. P.

Architecture, Styles of. *See* BYZANTINE, INDIAN, ITALIAN, POINTED, GOTHIC, ANGLO-SAXON, NORMAN, EARLY ENGLISH, TUDOR, ELIZABETHAN, STUART, *and* RENAISSANCE STYLES.

Architrave (*Architect.*) The lowest of the three chief members of an entablature. It is the main beam, and rests directly on the columns. It is also known as the EPISTYLE. The term ARCHITRAVE is also used to denote the moulding bounding the head and sides of a door or window opening. *See* ARCHITECTURE, ORDERS OF, ENTABLATURE, *and* COLUMN.

Architrave Block (*Carp., etc.*) The block at the bottom of the architrave moulding around a door opening into which the skirting is fitted or "finished."

Archivolt (*Architect.*) The mouldings on the face, and following the curve, of an arch.

Arc Lamp (*Elect. Eng.*) A pair of carbon rods connected to a current of sufficiently high voltage to produce an electric arc between the poles or ends of the carbons. This requires about 50 volts continuous or 33 volts with an alternating current. The carbons are connected to mechanism worked by the current which brings them together when the current is first turned on, then separates them a short distance (thus "striking" or setting up the arc), and then "feeds" the carbons or brings them up to a constant distance as they are burnt away. The chief differences between lamps consist in the nature of the mechanism employed for this purpose.

Arco (*Music*). With the bow; used after *pizzicato*.

Arctic. A general term applied (1) to organisms which resemble or are connected with those which live in the circumpolar regions; (2) to climatic or other geographical conditions resembling those found in those regions; or (3) to strata which have been formed in the same manner as those occurring in the Arctic regions.

Arctic and Antarctic Zones (*Astron.*). The part of the earth's surface lying between the Arctic or Antarctic Circles, and the respective poles.

Arctic Circle (*Astron.*) A circle or parallel of latitude, north of which the sun remains above the horizon for twenty-four consecutive hours during some portion of the year. This latitude is 66° 32′ 30″. The corresponding south latitude is called the Antarctic Circle.

Are. *See* WEIGHTS AND MEASURES.

Area. The amount or measure of a surface. *See* WEIGHTS AND MEASURES).

——, **Dry** (*Building*). In order to prevent dampness in the floors and walls of houses with basements, a "dry area" is constructed. A space is left all round the basement, of sufficient width to keep the damp soil from the walls. This is covered at the top, except in certain places where openings are left for ventilation. The drainage of the area requires particular attention.

Areal Velocity (*Astron., etc.*). The area swept out in unit time by the line joining a planet to the earth. Kepler's Second Law states that this areal velocity is a constant for any given planet.

Areas. *See* SANITATION—DWELLINGS.

Areca Nut. *Areca catechu* (order, *Palmæ*). The seeds are used in pharmacy, and in the East for chewing.

Arenaceous Rocks (*Geol.*) Sedimentary rocks of derivative origin, which consist essentially of grains of sand. They include not only sand, but also sandstone, quartzile, and grey wacké. They are simply aggregations of particles of quartz, which have been derived from the waste of some pre-existent rock containing that mineral. Arenaceous rocks are specially characteristic of rocks of terrigenous origin, and rarely or never enter into the composition of those formed in the deep sea.

Arenig Beds (*Geol.*) Strata of Lower Ordovician age, which are on the same geological horizon as those which form the Arenig Mountains in Wales. They differ much in mineral character in different parts of Britain, consisting largely of volcanic materials in Wales and the north-west of England, of deep sea radiolarian oozes in the south of Scotland, and probably of limestone in the north-west. They contain a characteristic suite of graptolites and trilobites in the area where they consist of argillacean sediments.

Argal *or* **Argol**. The reddish-brown crust which forms when wine is kept in bottles or casks. It is impure acid potassium tartrate (cream of tartar), and constitutes the source of tartaric acid (*q.v.*) and its salts.

Argand Burner. The name was originally applied to an oil burner having a wick enclosed between two concentric tubes. The burner is now used extensively for burning gas, and consists of a hollow ring, through the upper surface of which the gas issues by a number of small holes. To protect the flame a glass chimney is provided, by which also the entrance of air is regulated. *See also* ARTIFICIAL ILLUMINANTS.

Argent (*Her.*) Silver: usually contracted to *ar*: on a shield it is shown blank.

Argentic. *See* ARGENTUM.

Argentite (*Min.*) Sulphide of silver, Ag_2S: silver = 87·1, sulphur = 12·9 per cent. Occurs in cubic crystals of a black lead grey colour: very similar to galena, from which it is distinguished roughly by being sectile. Nearly all galena contains some silver, which probably exists as the isomorphous sulphide argentite. From Cornwall, Norway, Bohemia, Saxony, Mexico, Chili, Peru, and many localities in North America.

Argentum. The Latin name for silver. From this word the symbol Ag for silver is derived, also the word argentic, which is applied to the silver salts—*e.g.* argentic nitrate is silver nitrate.

Argillaceous (*Geol.*) Claylike: containing clay.

Argillaceous Rocks (*Geol.*) Strata consisting essentially of clay, and thus always primarily of derivative and sedimentary origin. Mud, clay, mudstone, shale, marl, argillite, and Lydian stone are amongst their varieties. Many (but by no means all) slates are also of argillaceous composition, as also are the dynamically metamorphosed rocks known as phyllites.

Argillite (*Geol.*). A name restricted to rocks of argillaceous composition and sedimentary origin, which have been much indurated by pressure and other causes, but which have not been affected by cleavage (*see* SLATES), nor by dynamic metamorphism (*see* PHYLLITE), nor by thermo-metamorphism (*see* LYDIAN STONE, JASPER etc.) The arenaceous associate of argillite is usually GREY WACKÉ (*q.v.*)

Argon. A gas forming rather less than 1 per cent. of the atmosphere. Its presence in the air was first

indicated by the fact that a litre of nitrogen prepared from air was found to weigh heavier than a litre of pure nitrogen obtained in other ways. It can be obtained by passing electric sparks through air in presence of caustic potash, and gradually adding oxygen till all the nitrogen has been converted into potassium nitrite and nitrate. Atomic weight, 40. Has a characteristic spectrum, a monatomic molecule (*q.v.*) It appears to be incapable of entering into chemical combination with any other element or compound whatever.

Aries, First Point of (*Astron.*) The point of intersection of the celestial equator and ecliptic, through which the sun passes as it crosses from south to north of the equator.

Aril (*Botany*). An outgrowth upon the seed coat or testa, either as an investment or as an excrescence. The mace of the nutmeg and the fleshy cup of the yew fruit are examples.

Arkose (*Geol.*) A name originally applied to any conglomerate which contained felspar fragments, whether decomposed or not; but now restricted to derivative rocks which have been formed under arid conditions and in which the parent rock has been a granite or a gneiss. Arkose thus differs from a conglomerate in containing, along with quartz or other mineral fragments, pieces of *undecomposed* felspar. A typical arkose occurs abundantly in the Torridon sandstone. It is also found in the Old Red.

Armature (*Architect.*) A term used for bars of iron added to various parts of architectural structures to strengthen them without detriment to the decorative effect of which they form a part—*e.g.* iron cross bars in a leaded window.

—— (*Elect. Eng.*) (1) The piece of soft iron which is placed in contact with the poles of a permanent magnet to aid in retaining the magnetic lines; (2) a piece of soft iron on which the magnet acts by magnetic attraction in order to actuate some piece of electrical apparatus, such as a relay (*q.v.*); (3) the rotating portion of a dynamo or electric motor. *See* ARMATURES.

Armature Binding (*Elect. Eng.*) Strips of thin metal or wire bands which hold the windings close to the iron core.

Armatures of Dynamos. An armature is the portion of the dynamo in which the current is actually produced. It usually consists of coils of wire rotating in the strong magnetic field between the poles of the magnets. This rotation produces a continuous variation in the number of lines of force which pass through each coil of the armature, and therefore a current is caused to flow through these coils. The current is led from each coil to the corresponding bars of the commutator, and is collected by means of brushes. In the majority of cases the coils are carried on a cylindrical core of soft iron, which serves the double purpose of acting as a support to the windings and also of concentrating the lines of force between the poles, and causing them to pass through the coils of the armature.

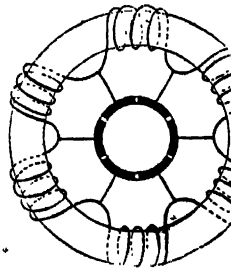


FIG. 1.

Armatures may be divided into four main types: (1) RING ARMATURES: A typical ring armature is shown in fig. 1 in a diagrammatic form. In this case there are six coils wound on an iron ring, the beginning of one coil being connected to the end of the preceding one, and the point of junction being also connected to a bar of the commutator, which is shown in black shading in the diagram. As each coil passes through what is termed the "neutral point"—that is, the position in which the current in it becomes reversed —the commutator bar to which it is connected passes from contact with one brush to contact with the next, and by this means the current in the external circuit is kept flowing in the same direction. The essential point to notice about a ring armature is that the windings pass over the external surface of the iron core, and return through the inside of the core.

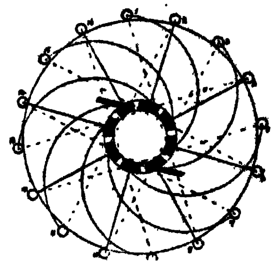

FIG. 2.

(2) DRUM ARMATURES: This is the form chiefly used in large continuous current machines. In this case the windings are all external to the iron core. The method of connecting the windings is varied and complex. One method is shown in fig. 2. In this case sixteen conductors, numbered 1 to 16, are shown on the outside of the armature. The method of connecting them at the end of the armature nearest the commutator is shown by continuous lines, and the connections at the farther end are shown by dotted lines. It will be seen that conductor No. 1 is connected at the back of the armature to No. 8, No. 3 is connected to No. 10, No. 5 to No. 12, and so on.

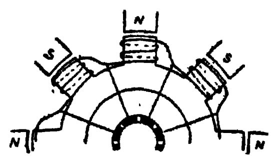

FIG. 3.

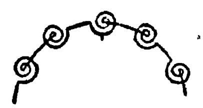

FIG. 4.

(3) POLE ARMATURES: This form is shown in fig. 3. It is very frequently used in alternate current machines, where field magnets with a large number of poles are employed.

(4) DISC ARMATURES: These are armatures where the wire is wound into flat coils of spiral or similar form. In this case there is no iron inside the coil of the armature; but the coil is made very thin, and very nearly occupies the whole of a very narrow gap between each pair of poles of the field magnets. The winding of a disc armature is shewn diagrammatically in fig. 4, and the form actually taken by the coils in fig. 5.—G. F. G.

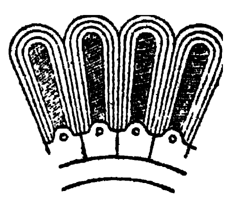

FIG. 5.

Armed (*Her.*) Used to denote that the natural weapons of defence are of a tincture different from the rest of the animal.

Armes Parlantes (*Her.*) Coats of arms on which

the device is derived from the family name; also called CANTING HERALDRY.

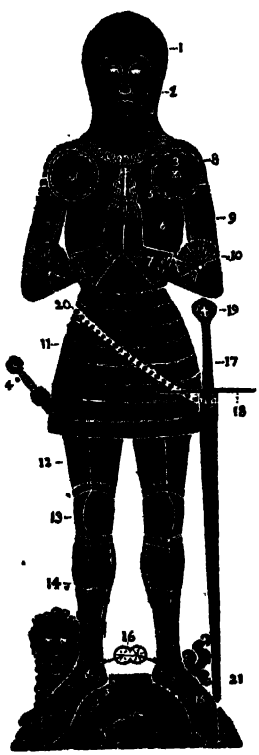
Armet (*Arm.*) A helmet worn on the Continent in the fifteenth century. It was globular in form.

Armilausa (*Cost.*) "A body garment, the prototype of the surcoat."—MEYRICK.

Arming Press (*Bind.*) A light kind of blocking press (*q.v.*) used by hand. So called originally because such presses were generally employed for impressing *armorial bearings* on the sides of books.

Armorial Bearings. Heraldic devices used to distinguish families, corporate bodies, and counties; in the case of family and feudal arms descending from father to son. ARMS OF DOMINION: The national arms borne by the sovereign. Armorial bearings were first employed by the Crusaders, and took their rise from knights painting upon their banners a distinctive figure to enable them to be distinguished when clad in armour. They became hereditary in families at the close of the twelfth century. *See also* HERALDRY.

Armour (*known also as* **Harness** *and* **Mail**). A covering worn to protect the body in battle. Metal armour of various kinds was used extensively by ancient nations, notably by the Egyptians, Greeks, and Romans; but it served to protect a portion of the body only, and consisted of helmet, shield, cuirass, and greaves. It is known that the *Hastati* of the Romans wore flexible cuirasses, but there is no definite evidence as to how they were constructed. It was in the tenth century that complete metal armour began to be worn in Europe, and it continued to be worn, subject, of course, to many variations of both style and construction, until the eighteenth century, when the more general use of firearms and field artillery rendered it useless. MAIL, the type of armour worn in the tenth century, consisted of rings of iron firmly sewn flat on cloth or leather. Later the rings were linked, and formed a garment themselves. This form of armour was known as CHAIN MAIL. Small flat pieces of metal were also used, and this armour is known as SCALE ARMOUR. Subsequently single plates were substituted to cover various parts of the body, until eventually, in the fourteenth century, the period during which the greatest development in body armour occurred, the whole body became encased in this kind of armour, known as PLATE ARMOUR. This, the last form of complete body armour, was often richly engraved and embossed. The illustration shows a complete suit of plate armour of the early fifteenth century, the names of the various parts being indicated.—C. F. T.



1. Bascinet.
2. Gorget.
3. Roundel.
4. Miséricorde.
5. Gadlings.
6. Cuirass.
7. Gauntlet.
8. Epaulière.
9. Brassart.
10. Coudière.
11. Skirt of Taces.
12. Cuissart.
13. Genouillière.
14. Jambart.
15. Solleret.
16. Rowelled Spur.
17. Sword.
18. Crossguard
19. Pommel.
20. Sword-belt.
21. Chape.

ARMOUR: SIR JOHN LYSLE, THRUXTON, HAMPSHIRE.
From "Brass," engraved c. 1425.

Armourer's Art. Originally, simply to make the armour, but afterwards to apply enrichment.

Arms (*Her.*) *See* ARMORIAL BEARINGS (*Her.*)

Arnott's Valve. The purpose of this valve is to act as an outlet for the vitiated air of rooms. It is a metal box arrangement, generally placed near the ceiling and opening into the chimney. The pressure of air from the room forces the valve inwards—*i.e.* towards the chimney—allowing impurities to escape; but when the pressure is greater from the chimney the valve closes.

Aromatic Compounds. A term originally applied to a number of substances having an aromatic odour. Most of these were found to be benzene derivatives; hence the term is now used to designate the benzene derivatives as a whole.

Arpeggio (*Music*). The sounding of the notes of a chord in succession instead of simultaneously.

Arquebus, *or* **Arcubus,** *also* **Harquebus.** Earliest form of trigger gun.

Arraché (*Her.*) *See* ERASED.

Arrack. The spirit distilled from the fermented liquor (toddy) of the sap from various palm trees.

Arras. A rich cloth originally woven at Arras in France; also the name of a screen of the same material which was hung round rooms.

Arris (*Building*). The sharp exterior angle formed by the intersection of two plane surfaces.

Arris Gutter (*Building*). A V-shaped gutter.

Arrow. A weapon of great antiquity, which varied much in length and shape; generally it was slender, straight, and pointed. Thick ones used with cross-bows were called bolts or quarrels. The arrows of the early Britons were tipped with flint or bone. After the Norman Conquest the English became most expert bowmen with the deadly "cloth-yard" shaft.

Arrowroot. Is obtained from the rhizomes of a plant, *Maranta arundinacea* (*Marantaceæ*), which is a native of India and the West India Islands. It is said to owe its name to the Indians using it to absorb the poison from wounds inflicted by poisoned arrows. Arrowroot is a pure starch, and is of value as an article of diet for invalids. The common adulterants are tapioca, potato starch, and sago.

Arsenic, As. Atomic weight, 75. A dark grey metallic-looking element. It is brittle and crystalline, and sublimes about 450° without melting; but it melts if heated under pressure. Its vapour has a tetratomic molecule at 860°, a diatomic molecule at 1736°. Heated in air, it is oxidised to arsenious oxide; the same oxide is formed when it is heated with strong sulphuric acid. Nitric acid oxidises it to arsenic acid. Hydrochloric acid is without action. The element is obtained by heating arsenical pyrites (FeS_2FeAs_2) out of contact with air. Alloyed with lead in shot making. In nature, arsenic

occurs in masses of tin white to dark grey colour, with a sub-metallic lustre; the masses are granular and often mammillated. Usually some antimony is present as an impurity, and it is often associated with lead and silver ores. Arsenic also occurs in combination as ARSENOLITE, ORPIMENT, REALGAR, and many arsenides and arseniates. Native arsenic is found in Cornwall, Saxony, Bohemia, Norway, United States, etc.

Arseniate of Lead (*Min.*) A synonym for MIMETITE (*q.v.*)

Arsenical Nickel (*Min.*) A synonym for KUPFERNICKEL (*q.v.*)

Arsenical Poisoning. Arsenic is used in the colouring of artificial flowers, toys, etc. It has also been found to a large extent in some wallpapers, the poison being given off either in the form of dust particles or as a gas.

Arsenical Pyrites (*Min.*) A synonym for MISPICKEL (*q.v.*)

Arsenic Compounds. ARSENIURETTED HYDROGEN, AsH_3: Formed pure when an alloy of zinc and arsenic is acted on by hydrochloric acid; mixed with hydrogen when any soluble arsenic compound is acted on by pure zinc and dilute sulphuric acid. It is a gas; extremely poisonous; resolved into its elements when heated (*see* MARSH'S TEST). Passed into silver nitrate solution, it gives a black precipitate of silver and a solution of arsenious acid. Traces of it are supposed to be formed from wallpapers coloured by green arseniacal pigments. ARSENIC CHLORIDE, $AsCl_3$: A colourless fuming liquid decomposed by water into arsenious and hydrochloric acids. Formed by direct union of its elements. ARSENIOUS OXIDES, As_4O_6; also called WHITE ARSENIC: A heavy white solid having three allotropic modifications; sparingly soluble in water; more soluble in hydrochloric acid; very soluble in alkalis forming alkaline arsenites. Very poisonous. Obtained on large scale in roasting tin ores containing arsenical pyrites. ARSENIC OXIDE, As_2O_5: White deliquescent solid obtained when arsenic acid is carefully heated. ARSENIC ACID, H_3AsO_4: A white solid, obtained when arsenic or arsenious oxide is oxidised with nitric acid. ARSENATES: Salts of arsenic acid. The most important is. SODIUM ARSENATE, $Na_2HAsO_4 12H_2O$, obtained when arsenic acid is made alkaline with sodium carbonate and the solution crystallised. It is isomorphous with sodium phosphate, and used in dyeing. ARSENITE: Salts of arsenious acid, H_3AsO_3. COPPER HYDROGEN ARSENITE, $CuHAsO_3$, is Schule's green—an important green pigment formed by adding copper sulphate solution to a solution of arsenious oxide in caustic soda. ARSENIOUS SULPHIDE, As_2S_3: Formed as a yellow precipitate when sulphuretted hydrogen is passed into an acid solution of an arsenic compound (important test for arsenic). Insoluble in hot strong hydrochloric acid; soluble in alkalis and alkaline sulphides. Heated in air, gives arsenious oxide.

Arsenolite (*Min.*) Also called white arsenic. It is native arsenious acid, As_2O_3, and occurs as a sublimate of minute octahedral crystals of glittering lustre on decomposing arsenical ores, and also in pulverulent crusts. It is extremely poisonous. From the Harz and Saxony and many localities where arsenical ores occur. Its crystallographic system is cubic.

Arsine. *See* ARSENIURETTED HYDROGEN, *under* ARSENIC COMPOUNDS. It is another name for this.

Artemis. The Greek name of Diana, goddess of the moon and of hunters. Represented as a huntress. The incident of Actæon, turned into a stag, being torn to pieces by his own hounds for gazing on the goddess while bathing, is a well known subject in art.

Artery (*Zoology*). The term applied to a blood vessel that contains blood passing from the heart to the various organs. The arterial walls are thick and very elastic.

Artesian Wells. These derive their name from the fact that the first well of the kind was sunk in the province of Artois in France. They are formed by making a perpendicular boring, usually of great depth, in a basin of the strata. When the boring reaches below an impervious stratum, a constant and spontaneous supply of water is afforded. The water from this source is pure and palatable. Sodium chloride, sodium carbonate, and free ammonia are often found in waters obtained from these wells.

Artificial Illumination. The chief illuminants are: coal gas, electric light, acetylene, and oil. Lighting is responsible for the addition of many impurities to the air of rooms, carbon dioxide in particular. It is computed that each cubic foot of gas burnt per hour pollutes as much air as would be rendered impure by a person while at rest. The following is a list of illuminants in their "hygienic" order: Electric light; coal gas—incandescent; coal gas—Argand burner; coal gas—batswing burner; paraffin lamp; and candles.

Artificial Stone. Artificial stones may be divided into three classes: (1) Stone resembling concrete, consisting of admixtures of cement and crushed fragments of some hard natural stone. (2) A soft natural stone which has been hardened and made stronger by artificial treatment. (3) Homogeneous "stone" prepared from various mixtures of clay, such as terra-cotta or common brick. (1) The chief forms of the first class are as follows: (*a*) GRANOLITH (Stuart's): This consists chiefly of crushed granite mixed with Portland cement. It is chiefly used for paving, in which form it is very durable. It also possesses the valuable property of withstanding intermittent action of water, and it has been used in the graving dock at Glasgow with success. (*b*) NON-SLIP STONE: This consists of chips of hard Yorkshire stone mixed with cement. It is cast in blocks and hardened under hydraulic pressure, forming a very durable paving material, with a surface which does not become too smooth, and therefore slippery, as it wears away. (*c*) VICTORIA STONE: This contains crushed granite, which has been washed free from alkali. This is mixed with cement and water, and moulded into suitable blocks. When it has been hardened by exposure to the air, it is soaked in a solution of sodium silicate and further exposed to the air, when it becomes extremely hard and durable. It is very suitable for paving, sills of doors, etc. (2) In the second class a good example is what is termed MOREAU MARBLE. The preparation of this is, in brief, a method of producing a fairly hard ornamental marble from a cheap and inferior limestone. A soft limestone is selected, and the surfaces dressed and smoothed. Veins are produced by tinting the stone artificially. It is then soaked in a solution of zinc sulphate and allowed to dry, first at 50° C. and then at 100° C. It has now become very hard, and is capable of taking a very high polish. With the exception that it cannot be obtained pure white, it has nearly all the valuable properties of natural marble. (3) In the third class

the method of formation is analogous to the manufacture of bricks, which are, in a sense, a form of artificial stone. For the method employed, *see* the article on BRICKS.—G. F. G.

Artisan. A skilled workman or mechanic. The name was formerly applied to artists.

Artist. One skilled in some branch of the fine arts: a good workman in any trade.

Artist's Proof. *See* PROOF.

Art Paper for Lithographic Printing. Ordinary paper (usually made from esparto and wood) coated with a mixture of china clay or barytes and glue.

Asafœtida. *Ferula narthex* and *F. Assafœtida* (order, *Umbelliferæ*). A gum resinous drug obtained by cutting and scraping the roots. Owing to its powerful odour, it is sometimes used in solution for detecting faults in drains.

Asbestos *or* **Asbestus** (*Min.*) A fibrous variety of amphibole; the fibres are usually so fine as to be flexible and separated by the fingers easily. Amianthus is an even more silky form. A typical analysis is: silica = 59·2, magnesia = 31·0, ferrous oxide = 8·3, alumina = 0·19, hydrofluoric acid = 1·31 per cent. It is found in Corsica, Savoy, Tyrol, Hungary, etc., and largely in the United States. Asbestos is very incombustible, and serves as the basis of various forms of fireproof card, cloth, and paper, which are of great value in the arts. Pipes conveying steam, hot gases, etc., are often coated with a preparation of asbestos.

Asbolane (*Min.*) This mineral, though used as an ore of cobalt, is really an impure hydrous oxide of manganese, WAD (*q.v.*), containing a variable proportion of oxide of cobalt. It is also called EARTHY COBALT. It occurs in earthy black masses with somewhat unctuous touch. Found in Cornwall, Saxony, United States, etc.

Ascending Letters (*Typog.*) All letters with upstrokes, as b, d, h, k, l, etc.

Ash. The residue which remains when organic matter of vegetable or animal origin is heated with exposure to air; *e.g.* bone ash is the residue—chiefly calcium phosphate—left when bones are heated in the air.

—— (*Dec.*) This wood is imitated by grainers by painting a ground obtained by mixing burnt umber and raw sienna with a little black. The graining is done with yellow ochre and burnt umber, or a mixture of raw sienna, burnt sienna, and raw umber. *See* WOODS.

Ashlar (*Building*). Masonry built of rectangular blocks over 12 in. deep on face.

Ashlaring (*Carp.*) Where a room is formed in a roof, the rafters cut the floor level at an acute angle. Short studs (ashlars) are fixed to the rafters and joists, and then lathed and plastered.

Ash Pan (*Eng.*) The tray placed beneath the bars of a grate or fire box to catch the ash.

Ash Rims (*Cycles*). *See* WOODEN RIMS.

Asp (*Archæol.*) A species of viper found in Egypt; in colour greenish, mingled with brown. Often figured on Egyptian monuments. Symbolical of malice.

Asparagine, $\begin{array}{l} CH_2CONH_2 \\ | \\ CHNH_2COOH \end{array}$. A white crystalline solid found in many plants; sparingly soluble in water and alcohol; it contains an asymmetric carbon atom (*q.v.*) The lævo form occurs in asparagus, peas, beans, lettuce, etc., and has a disagreeable taste. The dextro form, which occurs along with the lævo form, in the sprouts of vetches, has a sweet taste. Can be made artificially by heating maleic anhydride (*see* MALEIC ACID) with alcoholic ammonia.

Aspartic Acid, $\begin{array}{l} CHNH_2COOH \\ | \\ CH_2COOH \end{array}$. (*Aminosuccinic Acid*). A decomposition product of albumin, obtained by boiling asparagine with an acid. Crystalline solid. Has an asymmetric carbon atom (*q.v.*) The natural acid is lævorotatory. It yields malic acid when acted on by nitrous acid.

Aspectant (*Her.*) The same as AFFRONTÉ.

Aspen. *See* WOODS.

Asperges (*Archæol.*) Holy water sprinkler, used in the service of the Roman Catholic Church.

Asphalt. A native mixture of hydrocarbons which occurs under a great variety of conditions. It is very often associated with deposits of gypsum and of rock-salt, or with strata which have been formed in the concentrated solution found in inland lakes. It occurs also in rocks of very diverse ages. The asphalt of the Val de Travers, Neuchâtel, occurs in a bituminous limestone of Neocomian age. The Dead Sea and the Pitch Lake of Trinidad are other well known localities. The composition of asphalt varies almost as much as its mode of occurrence. Asphalt is valuable, in building, for making waterproof courses and for paving purposes, both as a cement for wood blocks and as the basis of various excellent paving compositions.

Asphaltum (*Paint.*) A brown paint made from asphalt.

Asphyxiator (*Plumbing*). An apparatus for testing drains by charging them with smoke.

Aspiration, Ventilation by (*Hygiene*). Is the extraction or withdrawal of the impure air (generally by the aid of machinery), fresh air rushing in to take its place. The ordinary chimney illustrates the method very well. Steam jets discharging into chimneys, fans, and screws are used in this system of ventilation. It is more effective and less costly than the propulsion method, though the air is not so easily controlled as in the latter.

Assai (*Music*). Very, sufficiently.

Assimilation (*Botany*). A process carried out in the green portions of a plant, and consisting of the absorption and decomposition of the carbonic dioxide in the air. The agent in the process is the chloroplastid (*q.v.*), and the source of energy the sunlight.

Astatic Needles (*Elect.*) A pair of magnetic needles of equal magnetic moment fixed together with their poles in opposite directions, and mounted so as to turn freely. This arrangement is exceedingly sensitive to a small magnetic force, owing to the controlling force due to the earth's magnetism being reduced to a minimum. Such a combination of two magnetic needles is used in the astatic galvanometer. *See* GALVANOMETERS.

Asteroid (*Astron.*) The minor planets lying between Mars and Jupiter. Over three hundred of these bodies are known.

Astragal (*Architect.*) A small moulding of semicircular cross section. *See* TORUS *and* BEAD.

Astragal (*Carp.*) A semicircular bead above the surface of the framing.

—— (*Plumbing*). A bead moulding round a lead pipe.

Astragalus (*Archæol.*). The knuckle bone. It has been used in a child's game from the time of the Greeks till now.

Astrakhan (*Zoology*). The fleece of black lambs of a variety of sheep (*Ovis aries steatophyga*), found in the province of Astrakhan, and in Bokhara, Persia, and the Asiatic steppes generally. The wool of the lambs of this species is curled, and resembles fur; but the coat of the adult sheep consists of short close hair, and yields no wool capable of being manufactured.

—— (*Woollen Manufac.*) A type of pile fabric covered with curls and made in imitation of the natural skin.

Astronomical Clock. A clock keeping sidereal time (*q.v.*) It indicates 0h. 0m. 0s. when the first point of Aries crosses the meridian.

Astronomical Telescope (*Light*). A telescope consisting essentially of a long focus lens forming a real image at or near its focus, and an eyepiece by which this image is magnified. The image seen by the eye is inverted, but this is no disadvantage when viewing a heavenly body.

Astronomy. The science that deals with the position, nature, and motion of the heavenly bodies.

Astylar (*Architect.*) A method of treating an elevation of a building without the use of columns.

Asymmetric Carbon Atom. Carbon is a tetravalent element (*q.v.*) When two or more of the atoms, or groups of atoms, attached to a carbon atom are the same, only one compound is known—*e.g.* only one compound of the formula $CHCl_3$ is known. But when all the four atoms, or groups of atoms, attached to a carbon atom are different, two compounds are known. These two compounds differ only in one important respect: the one rotates the plane of polarisation of PLANE POLARISED LIGHT (*q.v.*) to the right, the other to the left. In chemical behaviour the two compounds are identical. In the formula for lactic acid,

$$\begin{array}{c} CH_3 \\ | \\ H - C - OH \\ | \\ COOH, \end{array}$$

the central carbon atom has four different groups attached to it; hence lactic acid exists in two forms, one of which is dextrorotatory and the other lævo-rotatory. If equal quantities of the two forms are mixed, we get a product which has no action on polarised light—it is said to be optically inactive (also called the racemic modification). The theory of Le Bel and Van t' Hoff accounts for the phenomenon as follows: the asymmetric carbon atom is assumed to be at the centre of a regular tetrahedron, and the four groups are attached one at each angular point. This will account for the two compounds. Let A, B, C be the base of the tetrahedron (in the plane of the paper) and D the apex (above the plane of the paper); fig. 1. Also let A, B, C, D represent the four different groups. This will be one modification. Now interchange any two of the groups, say B and D, we get fig. 2. Turn the tetrahedron about the *edge* A, C, so that the apex B again comes into the plane of the paper, fig. 3. In case (1) A, B, C run clockwise; in case (3) counterclockwise: thus we have two different compounds. If in case (3) any two letters are interchanged, we shall again get case (1), so that *only* two compounds are possible.

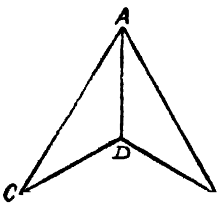


FIG. 1.

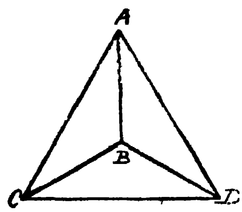

FIG. 2.

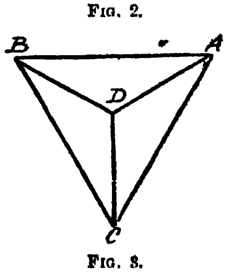

FIG. 3.

Asynchronous Motor (*Elect. Eng.*) Motors actuated by an alternating current may be classified as SYNCHRONOUS (*q.v.*) or ASYNCHRONOUS, according as the rate of rotation of the moving portion does, or does not, correspond to the frequency of the current. *See* MONOPHASE *and* POLYPHASE MOTORS.

Atacamite (*Min.*) A hydrous oxychloride of copper, $CuCl \cdot 3Cu(OH)_2$: oxide of copper = 53·6, chloride of copper = 30·2, water = 16·2 per cent. Colour, rich deep green; in small rhombic crystals; also massive. From Cornwall, the desert of Atacama in South America, Spain, Australia, etc.

At Bay (*Her.*) Said of a stag with a head bowed ready for attack or defence.

Atelier (*Art*). Literally a workroom or workshop: the studio of a painter or sculptor.

A Tempo (*Music*). In time: used after some term altering the speed.

At Gaze (*Her.*) Full faced or facing the observer.

Athene, Athena. In Greek mythology, the goddess of wisdom, arts, and sciences; represented with spear and helmet and the ægis of her father Zeus. Three celebrated statues of Athene were executed by Pheidias; the first, which was of ivory and gold, was erected on the Acropolis of Athens. Called by the Romans Minerva.

Athletes (*Art*). Those skilled in physical exercises. They have provided the best models for artists from the flourishing period of Greek sculpture to the present day.

Atlantes, *pl. of* **Atlas** (*Architect.*) The name given by the Greeks to the carved figure or half figure of a male used as a column. Persians and Telamones are other names for Atlantes. *See* CARYATID.

Atlas (*Paper*). Writing paper of a size 36 × 26 in.

—— (*Zoology*). The first of the neck (cervical) vertebræ. It has two large articular surfaces for the attachment of the skull.

Atmolysis (*Phys.*, *Chem.*) The separation of two gases by their different rates of effusion through a porous partition. The rates of effusion of two gases are inversely as the square root of their densities; thus hydrogen effuses four times as fast as oxygen, which is sixteen times as dense under equal conditions of pressure and temperature.

Atmosphere. Consists of nitrogen (76·95); oxygen (20·91); argon, and the allied elements helium, krypton, neon, xenon (1·00); carbon dioxide (0·04);

a variable amount of water vapour, ammonia as carbonate, nitrite, and nitrate; solid matter. The numbers give the percentage by volume. The nitrogen serves principally as a diluent, but certain leguminous and other plants obtain part of their nitrogen from atmospheric nitrogen through the agency of bacteria. The oxygen is essential for the respiration of all animals and plants, and for all processes of combustion. The carbon dioxide is produced in all processes of respiration, combustion, fermentation, and putrefaction; that it does not increase in amount appreciably is due to the fact that the green parts of plants decompose it under the influence of sunlight, using the carbon to build up their substance and liberating oxygen. Evaporation from seas, rivers, lakes, and the respiration of animals, as well as processes of combustion, furnish the water vapour. Ammonia owes its origin to the decay of nitrogenous organic matter, while the nitrous and nitric acids with which it is combined are formed by electrical discharges occurring in the atmosphere. Minute quantities of hydrogen peroxide and ozone are also present in the air of places far removed from towns; the true origin and amounts of these two substances are not known with certainty. The amount of nitrogen and oxygen is estimated (*a*) gravimetrically by freeing the air from other substances except argon and its allies, and passing it over red-hot copper and collecting the nitrogen; the increase in weight of the copper gives the oxygen, and that of the vacuous vessel in which the nitrogen is collected gives the nitrogen. (*b*) Volumetrically by means of the eudiometer (*q.v.*) The carbon dioxide is estimated by shaking a known volume of baryta water of known strength with 10 litres of air; part of the baryta unites with the carbon dioxide, and the rest is ascertained by titration with standard oxalic acid (Pettenkofer's method). Aqueous vapour is estimated by means of the hygrometer (*q v*), and also by aspirating a large volume of air (20 litres) through a weighed tube containing pumicestone soaked in sulphuric acid, which absorbs the water (absolute method). Ammonia and its compounds are determined in rain water only, as this washes them out of the atmosphere. The solid matter floats as dust in the air, which it can do in virtue of its fine state of division. It consists of silica, iron and its oxides, common salt (NaCl) from the spray of the sea, vegetable organisms, moulds, spores, and bacteria. Mr. Webb (L. & N.W.R. Co.) states that 18 tons of steel per day are removed from the rails of his company by wear and oxidation; doubtless much of this floats in the air as dust for long periods. The presence of moulds and bacteria is proved by the occurrence of fermentation and putrefaction. Milk turns sour because of numerous bacteria and moulds entering it from the air and producing lactic acid from the milk sugar. Putrefaction of meat is brought about in a similar manner. These changes do not occur in milk and meat kept in sealed vessels, when the vessels and their contents have been sterilised previous to sealing. The number of micro-organisms in the air is less in the country than in towns, and less at an altitude than near the ground. Thus Frankland has shown that at Reigate there were on an average 14 organisms in 10 litres of air: at St. Paul's Cathedral, 56 organisms at the base, 29 in the Stone Gallery, and 11 in the Golden Gallery, in 10 litres of air. The number of organisms is less in winter than in spring and summer. There are certain substances always present in the air of towns which are not present in pure country air; chief amongst these are sulphuric acid and products of the incomplete combustion of coal. The sulphuric acid owes its origin to the sulphur compounds present in coal and coal gas, and has a most injurious effect upon many kinds of stone, but not, apparently, upon healthy people. Incomplete combustion of coal produces soot, which consists of carbon and adhering tarry matters. To judge of the effect produced upon the atmosphere by the combustion of coal it is calculated that about 1 per cent. of the coal is given off as soot, a fair amount of which passes into the air; and 1 lb. of coal requires 240 cubic ft. of air for complete combustion. Fogs are produced in the atmosphere by the partial condensation of water vapour upon dust particles as nuclei: in the country the fogs are white, being of the same nature as cloud; but in towns the nuclei are largely the soot particles, and the yellow colour of the fog is due to soot and its accompanying tarry matter. In towns, too, during fog, the amount of carbon dioxide is much higher than in the country; it may be twice as much. In an inhabited room it may rise to ten times the normal amount. During respiration, besides carbon dioxide, putrefiable organic matter is given off, so that the bad effect of the air of a crowded room is due in part to this as well as to defect of oxygen. When the carbon dioxide from respiration reaches ·2 volumes per 1,000 above the normal value of ·4 volumes, the air of the room begins to have a close or stuffy smell; below this value the air can be breathed without any ill effects, but it should not be allowed to be further polluted.—W. H. H.

Atmosphere, Pressure of (*Phys.*) The hydrostatic pressure due to the weight of the air. It is approximately 15 lb. per square inch at the surface of the earth, and can support a column of mercury about 30 in. high. For many purposes of reference, an arbitrary standard of atmospheric pressure equal to that of 76 cm. of mercury is adopted. For some purposes a pressure of one million dynes per square centimetre is assumed, which is somewhat less than the "normal pressure," being more nearly equal to 75 cm. of mercury

Atmospheric Engine (*Eng.*) The earliest form of beam engine, in which the steam was suddenly condensed in the cylinder and the piston forced down by atmospheric pressure alone.

Atmospheric Line (*Eng.*) The line on an indicator diagram (*q.v.*) which is traced out by the pencil when at rest—*i.e.* when nothing but the pressure of the air acts on each side of the piston of the indicator.

Atolls. Annular groups of coral reefs and islets enclosing a central lagoon, and standing at a variable but small elevation above the level of the sea. Their slope beneath the sea on the inner side is usually at a low angle, while the outer slope usually plunges rapidly down into deep water. They appear to form a coronet upon the head of an elevated portion of the sea bottom. Their origin has given rise to much controversy.

Atom (*Chem.*) An atom (in the chemical sense) is the smallest particle of an element that can exist; that is, the atom is the limit of divisibility of the matter composing the element. This definition does not exclude the possibility of further division into smaller particles; it simply lays down the theory that the smaller particles cannot be regarded as having the properties of the element to which the

atom belongs. Experiment has now proved that these smaller particles do actually exist; they are given off during the passage of electricity through a gas at low pressures, and serve as carriers of negative electricity. The name ELECTRON or CORPUSCLE has been applied to them by various writers. An electron has been shown to have a mass not more than one-thousandth that of an atom of hydrogen Probably an atom of an element is a collection of these corpuscles, and the difference between the atoms of two different elements is due to a difference in the method of arrangement or of the mode of motion of the electrons constituting the atom. *See also* ELECTRON *and* RADIATION.

Atomic Heat (*Chem.*) This is the name given to the value of the product Atomic Weight × Specific Heat. It is equal to 6·4, and is constant (approximately) for all elements in the solid state. Boron, carbon, silicon, elements of low atomic weight and high melting point, give lower values than 6·4; but as the specific heat is determined at higher and higher temperatures, they become more nearly normal.

Atomic Theory (*Chem.*) This theory is the very foundation of modern chemistry; it had its origin in Dalton's Atomic Theory published in 1800. It assumes matter to be divisible up to a certain point only, the ultimate particles being called atoms. Atoms of the same element are all alike; but an atom of one element differs from an atom of another element in weight and in chemical properties. Where chemical combination occurs between two elements, it does so by means of their component atoms. This last statement accounts for the Law of Multiple Proportions (*q.v.*)

Atomic Volume (*Chem.*) The quotient

$$\frac{\text{Atomic Weight}}{\text{Specific Gravity}}$$

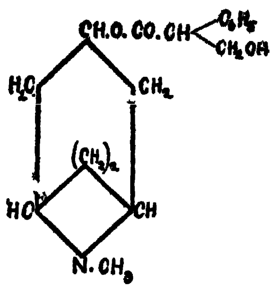
is called the atomic volume of an element. It is supposed to represent the relative volumes occupied by the atoms of elements.

Atomic Weight (*Chem.*) The smallest weight of an element which enters into a molecule of any of its compounds. The principle underlying the determination of atomic weight is as follows: Find the molecular weight (*q.v.*) of as many compounds of the element as possible. Analyse these compounds so as to determine the percentage of the element in each. Calculate from these two results the weight of the element contained in the molecular weight of each compound. The smallest value obtained is the Atomic Weight. In the case of elements in the solid state the Atomic Weight is related to the Specific Heat; thus: Atomic Weight × Specific Heat = 6·4 (Dulong & Petit's Law). The absolute weight of an atom of any element is unknown; so that the atomic weights have to be referred to some arbitrarily selected standard. Sometimes the atomic weight of hydrogen is put = 1, and all others expressed in terms of it; it is now very common to take the atomic weight of oxygen as = 16, and express all other atomic weights in terms of that, in which case H = 1·01.

Atomiser *or* **Atomising Carburetter** (*Motor Cars*). A SPRAY CARBURETTER (*q.v.*)

Atrium (*Architect.*) That court of a Roman dwelling house which was nearest to the entrance, and which served as a waiting room. The central portion of it was usually open to the sky. The same name is also given to the forecourt of an Early Christian Church. *See* PERISTYLIUM.

Atropine. An alkaloid obtained from the leaves and root of belladonna (deadly nightshade). Shining needles; can be sublimed; optically inactive. Soluble in alcohol and chloroform. Powerful poison; dilates the pupil of the eye. On treatment with nitric or acetic acids, it forms apoatropine, $C_{17}H_{21}NO_2$. On hydrolysis, yields tropin and tropic acid,



$$C_{17}H_{23}NO_3 + H_2O = \underset{\text{Tropin.}}{C_8H_{15}NO} + \underset{\text{Tropic acid.}}{C_9H_{10}O_3}.$$

Atropine can be reproduced by the union of these two substances. Atropine is isomeric with hyoscyamine, and the latter, on hydrolysis, also yields tropin and tropic acid.

Attacca (*Music*). Go on to the next movement without break.

Attachments (*Art*). The manner in which a limb is shown fastened to the body.

Attic (*Architect.*). The topmost story of a building above the main cornice.

Attic Base (*Architect.*) A base moulding used in Greek. Roman, and Renaissance architecture, consisting of two tori separated by fillets and a scotia.

Attic Order (*Architect.*) The pilasters used to decorate the front of an upper story above the main cornice.

Attired (*Her.*) The antlers of a stag.

Attracted Disc Electrometer (*Elect.*) *See* ELECTROMETERS

Attraction and Repulsion (*Physics, etc.*) A force between two bodies tending to draw them together or force them apart. These forces are now referred in most cases (*e.g.* in electric and magnetic phenomena) to certain actions of the nature of stresses and strains, produced in the medium between the two bodies. *See* LINES OF FORCE.

Audition, Limits of (*Sound*). Somewhat uncertain and variable with different observers. The lowest note audible is probably one of 30 vibrations per second; the highest may have from 10,000 to 20,000 vibrations per second. This gives a probable range of 9 octaves.

Auger. A tool similar to a gimlet, only much larger.

Augite (*Min.*) One of the pyroxene group of minerals, often in the form of short prisms. Black or very dark green. A silicate of calcium, magnesium, aluminium, iron, and manganese Silica = 17·63, lime = 20·87, magnesia = 12·9, alumina = 6·74, ferrous oxide = 11·39, manganous oxide = 0·21, water = 0·28 per cent. Monosymmetric. Found in many basic volcanic rocks, widely distributed.

Augite Diorite. A holocrystalline compound of ferro-magnesian minerals (including one of the pyroxenes) and a plagioclase felspar, in which the structure of the whole mass is granitic. It is always a rock of plutonic origin, and has generally been formed at a considerable depth below the surface.

The dyke rocks correlative to it are now termed PORPHYRITES, while the correlative lavas are ANDESITES. Augite diorite graduates into GABBRO DIORITE and then into GABBRO (*q.v.*)

Augite Syenite. A holocrystalline compound showing granitic structure, composed essentially of othoclase felspar (without any conspicuous development of quartz), together with ferro-magnesian silicates, amongst which one of the pyroxenes forms part. The rock is of sub-acid composition, and is of plutonic (and usually deep-seated) origin. Its correlative dyke rocks are various, and include the MICA TRAPS. The correlative lavas are TRACHYTES.

Augmentation (*Her.*) An addition to a shield to commemorate an important event in the life of its possessor.

Augmented Interval (*Music*). An interval containing one semitone more than perfect, or major.

Augur (*Archæol.*) Among the Romans a functionary whose office was to divine future events from the acts and flight of birds, natural phenomena, etc. There was a college of augurs, consisting in later times of four patricians and five plebeians. One of the symbols of office was the lituus or crooked staff.

Auramine, $\begin{matrix}(CH_3)_2N - C_6H_4\\(CH_3)_2N - C_6H_4\end{matrix}\!\!>C = NH$. Usually met with as the hydrochloride – golden yellow leaflets. A basic yellow dye used in cotton dyeing and printing. *See also* DYES AND DYEING.

Aureola, Aureole (*Art*). The luminous cloud which forms the background to the figure of Christ or a saint. If intended to symbolise Christ, a cross is enclosed in the aureola. When only encircling the head, it is termed NIMBUS: the nimbus and aureole together form a GLORY.

Aureoled (*Her.*) Figures having the head surrounded by an aureole (*q.v.*)

Aureolin (*Paint.*) A bright yellow pigment used by artists. It is somewhat fugitive when exposed to light and air, is dissolved in acids, but unaffected by alkalies.

Auric, Aurous, Aurum (*Chem.*) Aurum is the Latin word for gold, and the symbol for gold, Au, is derived from it. The terms AURIC and AUROUS are applied to the two classes of gold salts—*e.g.* auric chloride is $AuCl_3$; aurous chloride, AuCl.

Auricles (*Zoology*). The two thin-walled chambers of the heart, into which the great veins open.

Auriferous Deposits. A comprehensive name for all kinds of rocks which yield gold in any form. It includes quartz reefs, and all of the many forms of strata yielding detrital gold.

Auriferous Pyrites (*Min.*) A variety of pyrites (*q.v.*) containing a workable quantity of gold. Nearly all samples of pyrites contain some gold, but it is more difficult of extraction than when it exists as "free" or metallic gold in the matrix.

Aurora. A luminous appearance seen in the sky towards the poles; it is due to some electrical phenomena, probably of the nature of an electrical discharge, and is accompanied by MAGNETIC STORMS (*q.v.*)

Authentic (*Music*). *See* MODES.

Author's Proof (*Typog.*) Proof bearing the author's corrections.

Autogenous Soldering. The process of joining two pieces of lead (or other metals) by placing them together and melting the lead at the junction by means of a hydrogen flame.

Automatic Ignition (*Motor Cars*). Firing the charge by the heat of the cylinder at the moment when the compression has reached its greatest value. An engine with this form of ignition requires special means of starting, and is, moreover, rather uncertain in action.

Automatic Loom (*Cotton*). *See* LOOM.

Automatic Valves (*Motor Cars*). Valves which are worked by a difference of pressure between the gases on the two sides, instead of by valve rods or levers. The admission valve in very many petrol engines acts in this manner; as the piston descends, a partial vacuum is produced in the cylinder, and the pressure of the mixture of air and petrol vapour opens the valve and rushes in.

Automobile. A general term for a mechanically propelled carriage which carries its own motive power.

Auto-Transformer (*Elect. Eng.*) A form of transformer (*q.v.*) with one coil only, whose ends are connected to the mains, forming the primary. The secondary is furnished by making connection to any two points in the coil, thus obtaining a lower voltage but larger current, as in the ordinary transformer.

Autumnal Equinox (*Astron.*) The time when the sun crosses the equator from north to south, passing through the First Point of Libra (*q.v.*) *See also* EQUINOXES.

Autunite (*Min.*) A hydrous phosphate of uranium and hydrate of calcium $(CaO.3U_2O_3)P_2O_5.8H_2O$: uranic oxide = 56–60 per cent., phosphoric acid = 13–15 per cent., lime = 5·5 per cent., water = 15–20 per cent. It crystallises in yellow rhombic plates. Cornwall, Siebengebirge, Russia, United States.

Auxiliary (*Clocks*). A secondary compensation piece fitted to the balance of a marine chronometer to reduce the "middle temperature error."

Auxiliary Note (*Music*). An unessential dissonant note, a second above or below one of the notes of a chord with which it is sounded.

Avagadro's Law states that equal volumes of all gases at the same temperature and pressure contain the same number of molecules. It is of fundamental importance in chemistry, as it follows from it that if we weigh equal volumes of two gases under the same conditions, the ratio of these weights is the ratio of the molecular weights. The molecule of hydrogen is believed to contain two atoms, so that its molecular weight is 2. Hence, if we find how many times heavier a given volume of a gas is than the same volume of hydrogen under the same conditions, and multiply the result by 2, we have the molecular weight of the gas.

Avantail, *also* **Ventaile** (*Arm.*) The movable part of a helmet which covered the face. It was superseded by the visor in the fourteenth century.

Avellane (*Her.*) A cross whose quarters resemble a filbert nut. When placed on the mondes of royal personages, it is an ensign of sovereignty.

Aventurine, Avanturine (*Glass*). A brilliant variety of glass of a brownish colour flecked with small gold-coloured spangles. This quality is produced by the addition of oxide of copper. Avanturine glass was first manufactured at Murano, near Venice, about the year 1600.

Aventurine Felspar (*Min.*) A variety of orthoclase (*q.v.*) containing minute spangles of tetanic iron or limonite.

Aventurine Quartz (*Min.*) A variety of quartz containing minute flakes of mica, which give it, when cut, a scintillating appearance.

Average. A mean or intermediate quantity. If there be n quantities, q_1, q_2, q_3, etc., and their sum be Q, then the average value of these quantities, often written $\bar{q}$, is given by the equation

$$\bar{q} = \frac{q_1 + q_2 + q_3 + \text{etc.}}{n} = \frac{Q}{n}$$

Average Current (*Elect. Eng.*) The average value of an alternating current in the simplest case (that of a curve of sines: *see* ALTERNATING CURRENT) is ·637 of the maximum current; but the effective or virtual value, the one required to be known for practical purposes, as it is equal to the equivalent continuous current, is ·707 of the maximum current. This value is obtained by calculating the mean value of the square of the current at each instant, and taking the square root of this value.

Aversant (*Her.*) A right hand which is turned so as to show the back. Sometimes termed DORSED.

Avicula (*Zoology*). A genus of marine bivalve shells forming one of the sources of the mother-of-pearl used in commerce.

Avoirdupois. The English system of weights. *See* WEIGHTS AND MEASURES.

Axe (*Building, etc.*) A large wood-cutting tool for rough work. Also a pointed hammer used by masons for dressing hard stone.

Axed Arch (*Building*). An arch with bricks roughly cut to shape, instead of being carefully "rubbed" to gauge. *See also* ARCH.

Axed Work (*Building*). Hard stone, such as granite, which has been dressed with an axe, leaving the surface somewhat ribbed or rough.

Axes (*Min.*). Crystallographic axes are imaginary lines of indefinite length intersecting in a common *origin*. Their relative length varies in the different SYSTEMS (*q.v.*) They are determined by the optical properties of the crystal in the first place, and, further, from a consideration of the crystal as a whole. In systems showing symmetry the intersections of planes of symmetry are often crystallographic axes. From the optical point of view, the axis is a direction in a crystal along which there is only one index of refraction, and every ray passing along or parallel to this direction obeys the ordinary law of refraction.

Axe Stone (*Min.*) A synonym of JADE (*q.v.*)

Axial Pitch (*Eng.*) The pitch of a screw or helix (*q.v.*) measured parallel to the axis.

Axial Relations (*Min.*). A term used in reference to the proportionate lengths of the crystallographic axes and the angles between them. *See* SYSTEMS.

Axis. The centre line of a body, or the line about which a figure or solid is symmetrical.

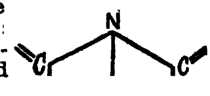
Axle (*Eng., etc.*) A rod or shaft with or on which a wheel or other rotating body turns.

Axle Box (*Eng., etc.*) The bearings or supports of an axle, combined with arrangements for lubricating the surfaces where friction occurs; practically a plummer block (*q.v.*), with a large oil or grease reservoir. Commonly used for railway carriages.

Azimuth (*Astron.*) The angle, measured horizontally, between a vertical circle through a star and the south point.

——, **Relative** (*Surveying*). The relative azimuth at a point A of the two points B and C is the angular distance, measured to the right, between one vertical plane passing through A and B, and a second passing through A and C.

Azines. Are compounds containing the group shown in the diagram. The simplest azine, phenazine, is a pale yellow crystalline solid with no dyeing properties; but many of the azines are important dyes—*e.g.* toluylene red (neutral red),



$$(CH_3)_2N.C_6H_3 \left\langle \begin{matrix} N \\ | \\ N \end{matrix} \right\rangle C_6H_2 \left\langle \begin{matrix} CH_3, \\ NH_2 \end{matrix} \right.$$

is an important cotton dye.

Azobenzene, $C_6H_5 - N = N -$ by reducing nitrobenzene with alkaline stannous chloride. Bright orange plates melting at 68°; insoluble in water, soluble in alcohol and ether.

Azo Compounds. Compounds containing the group $R_1 - N = N - R_2$, where R_1 may be an aromatic residue and R_2 either an aromatic or fatty residue; *e.g.* azobenzene is $C_6H_5 - N = N - C_6H_5$. Many azo compounds are important dyes—*e.g.* chrysoidine

$C_6H_5 - N = N - C_6H_3 \left\langle \begin{matrix} NH_2 \\ NH_2 \end{matrix} \right.$. *See also* CONGO RED, METHYL ORANGE, *and* DYES AND DYEING.

Azoimide, $\left.\begin{matrix} N \\ \| \\ N \end{matrix}\right\rangle NH$ (*Hydrazoic Acid*). A colourless liquid with penetrating smell, boiling at 37°; soluble in water and alcohol; explodes violently on heating. It is a strong acid; the salts with heavy metals are very explosive. May be obtained in aqueous solution by passing ammonia gas over sodium at 200°, forming sodamide; then passing nitrous oxide over the sodamide, dissolving in water, acidifying with sulphuric acid and distilling. Water is removed by fractional distillation, and then by calcium chloride. Also by action of nitrous acid on hydrazine (*q.v.*) and from amino-guanidine.

Azoxybenzene, $\begin{matrix} C_6H_5 - N - N - C_6H_5. \\ \diagdown\!\diagup \\ O \end{matrix}$

Long yellow needles melting at 36°. Obtained by reducing nitrobenzene with alcohol and sodium amalgam. Heated with iron filings, it gives azobenzene.

Azulejos. Wall tiles imitating mosaic work, made by the Spanish Moors in the fourteenth century, though some have been found made in the sixteenth century. Brilliant enamel colours were used. Excellent examples are to be seen in the Alhambra Palace, Granada. (2) A kind of glazed Dutch tile painted in colours.

Azulmic Acid, $C_4H_5N_5O$. A brown powder formed when a solution of cyanogen in water is allowed to stand.

Azure (*Her.*) Blue. It is generally contracted to *az*, and is indicated by horizontal lines in drawings.

AZURE.

—— (*Paint.*). Fine blue colour —*eg.* that of the sky. The name is sometimes given to cobalt and ultramarine.

Azurite (*Min.*) The blue carbonate of copper, $2CuCO_3 . Cu(OH)_2$, containing about 73 per cent. of oxide of copper; monosymmetric; deep blue in colour; it also occurs in the massive form (*q.v.*) It is a valuable ore of copper when in workable quantity. It is used to make the pigment mountain blue. Cornwall, etc., in Britain; Chessy in France; Siberia; Burra-Burra in South Australia, etc.

B (*Elect.*) Symbol for MAGNETIC INDUCTION (*q.v.*)

B (*Metallurgy*). The letter B is used to denote a quality of wrought iron; B.B. and B.B.B. indicate superior grades. *See* IRON, WROUGHT.

B (*Music*). The seventh note in the scale of C.

Babbitt's Metal (*Eng.*) A white alloy largely composed of tin, used for lining bearings to diminish the friction. A good composition is tin 96, antimony 8, copper 4 parts, by weight.

Babcock & Wilcox Boiler. *See* BOILERS.

Baccate Fruits (*Botany*). Succulent fruits usually termed berries, in which the seeds are embedded in a soft pulp. The date, orange, grape, currant, melon are examples.

Bacilli are micro-organisms, rodlike in shape. Many diseases are caused by organisms belonging to this group, as tuberculosis, typhoid, diphtheria, anthrax, influenza, etc. *See also* BACTERIA, ANTISEPTICS, *and* DISINFECTANTS.

Back (*Build.*) The extrados (*q.v.*) of an arch.

—— (*Carp.*) The top surface of a handrail, rafter, or any inclined timber.

Back Balance (*Eng.*) A disc-shaped weight used to counterbalance a loose eccentric which has to be moved on its shaft to reverse the engine; formerly commonly used on the engines of paddle steamers, but nearly obsolete owing to the use of LINK MOTION (*q.v.*)

Back Centre (*Eng.*) The "loose centre" or right-hand support of the work in a lathe.

Back Electromotive Force (*Elect. Eng.*) *See* COUNTER ELECTROMOTIVE FORCE.

Back Firing (*Eng., Motor Cars, etc.*) The explosion of the gas in the cylinder of a gas engine while the piston is performing the return stroke; or the explosion of unburnt gas after its release from the cylinder, before it escapes from the exhaust passages or from the silencer.

Back Gear (*Eng.*) An arrangement of gear wheels on the headstock of a lathe by which the velocity of the mandrel is made much less than that of the coned pulley through which the power is transmitted to the lathe. A pinion fixed to the pulley, which runs loose on the mandrel, drives a wheel on a parallel shaft, and a pinion keyed to the latter shaft drives a wheel keyed to the mandrel. When the reduced speed is not required the parallel shaft is thrown out of gear, and the loose pulley is fixed to the gear wheel on the mandrel. For very large lathes extra gearing for still further reducing the speed may be used.

Back Hearth (*Build.*) The portion of the hearth between the jambs, *i.e.* beneath the grate.

Backing (*Photo.*) Coating the back of a glass plate with a dull black substance, in order to prevent halation (*q.v.*)

Backing Boards (*Bind.*) Wedge-shaped boards made of hard wood, sometimes faced with iron. They are inserted between the book and the press in such a position as to help the binder when shaping the back of the book with the backing hammer, previous to binding. *See* BOOKBINDING.

Backing Off (*Cotton Spinning*). The reversing of the spindles on a mule so as to unwind the short length of spun thread coiled round during the operation of twisting and drawing out, previous to again winding on to build up the COP (*q.v.*)

Backlash (*Eng., etc.*) The amount of free movement between the two elements of a piece of gearing—*e.g.* in the case of a wheel and its pinion, the amount that one can be moved before the other commences to turn, or in a screw and nut the amount that one can be turned before the other begins to advance.

Back Lining (*Carp.*). The framing covering the wall under the window board.

Back Observation (*Surveying*). One made in a direction contrary to the order of a survey—*e.g.* one in which the eye is applied to the north sight of a miner's dial and not to the south. as in "FORE OBSERVATIONS."

Back Pages (*Typog.*) The pages of a printed sheet bearing even numbers are termed back or "verso" pages.

Back Painting. *See* CRYSTOLEUM.

Back Pedalling (*Cycles*). Checking the machine by pressing on the rising pedal; much practised by the riders of brakeless machines, but impossible on a free-wheel. In the latter case, however, a mechanical brake may be fitted, which is actuated by back-pedalling, the motion being given to the brake by a clutch on the axle which comes into action on pressing the pedals backward. *See also* CYCLES.

Back Plate (*Arm.*) The piece of armour which covered the back of the wearer.

—— (*Moulding*). A plate fastened to the back of moulding boxes to strengthen them when the molten metal is poured in.

Back Pressure (*Eng.*) The pressure in a cylinder due to the steam (or exhaust gas) which is still escaping by the exhaust port. Shown on the indicator diagram by the height of the bottom line of the diagram above the atmospheric line (*q.v.*) in non-condensing engines, or above the line of no pressure or absolute vacuum in condensing engines.

Back Putty (*Build.*) The putty put in the rabbets of a sash before the glass is inserted.

Back Rest (*Cotton Weaving*). The back crossrail or roller of loom over which the warp passes in a horizontal direction to the healds and reed.

Backs. A quarryman's term for one set of JOINTS (*q.v.*) traversing a rock, the other set being known as CUTTERS.

Back Saw. Any saw (*e.g.* a tenon saw) whose blade is stiffened by a bar fixed along one edge of the blade, the teeth being on the other edge.

Back Stay, or Back Rest (*Eng.*) A support for long work (*e.g.* shafting) which is being turned in the lathe; it prevents the work from springing away from the cutting tool. It travels with the slide rest, so as to be near the tool and close behind the point at which pressure is being applied.

Back Stops (*Cotton Spinning*). Buffers, used to prevent the mule carriage from going beyond a certain point during its inward run.

Backward Eccentric (*Eng.*) The eccentric used when the engine is reversed—*i.e.* one of the pair always used with link motion.

Backward Lead of Brushes (*Elect. Eng.*) *See* LEAD OF BRUSHES.

Backwasher (*Woollen Manufac.*) The machine through which the wool is passed after carding. It consists of the troughs containing the cleansing solution and of a number of hot drying cylinders over which the wool passes to a gill box.

Backwater Pump. A pump used in the manufacture of paper for conveying surplus water obtained from underneath the machine wire.

Bacteria. Minute unicellular plants devoid of chlorophyll (*q.v.*), and of a PARASITIC or SAPROPHYTIC habit (*see* PARASITES *and* SAPROPHYTES). They are found everywhere in nature. They attach themselves to the surface of every substance, and are present in varying numbers in air, water, etc. They are broadly divided into two classes—those that produce disease (the PATHOGENIC BACTERIA), and the harmless ones (the NON-PATHOGENIC BACTERIA). With conditions suitable to their growth and development they multiply with incredible rapidity. It is calculated that nearly seventeen million organisms are produced from one cell during twenty-four hours. Sunlight, heat, and certain chemical agents are destructive to many of these germs; their destruction is termed STERILISATION, and a substance capable of destroying them is termed an antiseptic, or in ordinary language "disinfectant," the latter word being also used in a somewhat wider sense.

Bacteriological Examination of Water. It is recognised that certain ZYMOTIC DISEASES (*q.v.*) can be produced by a contaminated water supply. These diseases are due to pathogenic bacteria (*see* BACTERIA). The presence of these disease-producing organisms can only be determined by bacteriological examination. It is extremely important, therefore, that water should be examined both chemically and bacteriologically.

Baculus (*Art. Archæol.*) Literally a stick; the long staff or rod used for support or as a symbol of power.

Bad Colour (*Typog.*) When too much or too little ink has been used.

Bad Copy (*Typog.*) A term applied to badly written MS.

Badge (=Cognisance in *Her.*) Originally a distinctive device borne by the followers of a knight; used later to identify the property of a person and as a sign of office. A badge cannot be regarded as armorial bearings.

Badger Plane (*Carp.*) A plane used for working wide rabbets.

Badgers (*Paint.*) Brushes made of badger's hair.

Badger Softener (*Dec.*) A broad flat brush the hairs of which are set to spread outwards, so that they may be lightly drawn over grained work during its progress to soften down the edges and smooth the marks representing the grain.

Badigeon (*Build.*) A mixture of plaster and stone used primarily for mending cracks in stonework. Afterwards used as a kind of paint or distemper to colour plaster work. A similar term is used for glue and sawdust worked up to repair woodwork.

Bad Matter (*Typog.*) A term applied to type intended for distribution.

Baffle Plate or Baffler (*Eng., etc.*) A plate fixed in the path of a moving fluid (liquid or gas) to check or alter the direction of flow. In furnaces it directs the hot gases (and therefore the flames) against parts required to be heated, instead of allowing them to pass directly along the flue.

Bag and Spoon Dredger (*Civil Eng.*) A dredging appliance resembling a large butterfly net, the ring round the net being strong enough to loosen material from the bottom of the river or channel.

Bag Hides (*Leather Manufac.*) Hides tanned for bag work. Light or half-tanned hides are split with a splitting machine, which divides the hide into two "splits." The upper or GRAIN SPLIT is used for bag work after being fully tanned and dyed. The lower or FLESH SPLIT is used for insoles and stiffeners in boots.

Bagshot Beds (*Geol.*) The Eocene strata which succeed the London Clay in the South of England. They are of marine origin and mostly consist of sands, which range to about 120 ft. in thickness. They are represented in Belgium by the Système Ypresian inférieur, and in the Paris Basin by the Lits Coquilliers. Beds of the same age are well exposed in the Isle of Wight.

Bainbergs (*Arm.*) Extra defences for the shin, made of iron or leather, and buckled over chain armour. Superseded eventually by greaves.

Baize. A coarse woollen material with a long nap, manufactured in Yorkshire.

Baked (*Typog.*) Said of type when caked together and hard to distribute.

Bakehouses (*Hygiene*). The Factory and Workshop Act, 1901, contains a long series of enactments for sanitary regulation of bakehouses. This regulation is a matter of considerable importance, not only on account of the large number of men employed in the trade, but also on account of the importance of bread as an article of food. An underground bakehouse cannot be used as such (Section 101) now unless the sanitary authority certifies that it is suitable as regards construction, light, ventilation, and all other respects.

Baking (*Pot.*) Firing the objects made of clay, which would otherwise fall to pieces when dry. *See* BISQUE OVEN, GLOST OVEN, ENAMEL KILN, ETC.

Baking Powder (*Hygiene*). Generally a mixture of bicarbonate of soda, tartaric acid, and some form of starch. When this mixture is moistened it gives off a quantity of carbonic acid gas, which aërates the bread and makes it light.

Bala Beds (*Geol.*) Rocks of Upper Ordovician age, typically developed in the Bala district of North Wales. They include rocks of both sedimentary and volcanic origin. In the typical district they are richly fossiliferous, and these fossils include

a great variety of graptolites, which occur in dark shales in deep water. An extensive suite of Brachiopoda and Trilobites is found in the other types of sediments.

Balance (*Physics, Chem., etc.*) A delicately poised beam or lever of the first kind, with equal arms, constructed so that the centre of gravity of the beam lies below the level of the fulcrum. From the ends of the beam hang the scale pans, supported by slings which turn on knife edges, so that they always hang vertically. *See also* SPRING BALANCE.

—— (*Paint.*) General harmony in a picture.

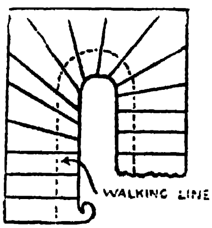
—— (*Watches*). The "fly wheel" of a watch, chronometer, or portable clock.

Balance Box (*Eng.*) A box containing the weights used to counterpoise a balance crane (*q.v.*)

Balance Crane (*Eng*) *See* CRANES.

Balance Cylinder (*Eng.*) A small cylinder containing a piston attached to the valve rod of a large vertical engine to neutralise the weight of the valve and rods, and hence to render the valve easier to move. The weight of the main piston is also balanced in the same way in some engines.

Balanced Steps (*Carp.*) The method of arranging the steps of geometrical stairs to increase the going (width) at the small ends of the winders, and to give a better falling line to the handrail.



BALANCED STEPS.

Balance Gear (*Motor Cars*). *See* DIFFERENTIAL GEAR.

Balance Spring *or* **Hair Spring** (*Watchmaking*). An elastic spring attached by one end to the collet of the balance, the other end being fastened to the stud on a fixed part of the movement. Its use is to restore the balance wheel to its position of rest after it has been displaced. *See also* BALANCE *and* BALANCE WHEEL.

Balance Weight (*Eng.*) A weight used to balance moving parts when running (*see* BALANCING) or merely to render some portion of a machine easier to move by hand, or to relieve any structure of undue stresses. An example occurs in the balance crane (*q.v.*)

Balance Wheel (*Clocks and Watches*). The regulating wheel of a watch or chronometer, whose alternate movement in opposite directions fulfils the function of a pendulum. It constantly tends to return to a fixed position of rest under the influence of a spiral spring attached to its axis (the balance spring or hair spring).

Balancing of Machinery. The adjustment of the moving parts so that the forces on the bearings, axles, etc., due to the movement, remain as nearly constant as possible. Thus a rapidly rotating wheel is properly balanced when it is absolutely symmetrical about its axis of rotation. Any unsymmetrical portion (*e.g.* a crank pin) must be compensated by the addition of a suitably adjusted counterpoise weight on the opposite side of the centre. A truly balanced machine should run without vibration or rocking when freely suspended in the air by chains or other means, and this test can actually be applied to many pieces of mechanism.

Balas Ruby (*Min.*) The rose-coloured variety of SPINEL (*q.v.*) Used as a gem.

Balata (*Botany*). ***Mimusops palata*** **(order,** ***Sapotaceæ*****).** A guttapercha from the stem of the Brazilian milk tree. It was introduced to replace the ordinary guttapercha.

Baldachino, Baldachin, or **Baldaquin** (*Architect.*) A canopy. Generally used to denote the canopy over an altar, which is usually supported on columns, but occasionally suspended from the ceiling. Also known as the CIBORIUM and as the TABERNACLE.

Baldric (*Cost.*) (1) A shoulder-belt, whence baldric-wise, worn across one shoulder and under the opposite arm. Generally used to suspend weapons. (2) The leather by which the clapper of a bell was at one time suspended. In old churchwarden accounts the term frequently recurs, as use soon wore out the leather, necessitating renewal.

Baldwin's Phosphorus. Calcium nitrate. Called Baldwin's Phosphorus because Baldwin observed that when heated it becomes phosphorescent, though it has no relation whatever to phosphorus.

Bale Breaker (*Cotton Spinning*). A machine used in the blowing room for loosening the matted fibres in the compressed bale. There are two kinds: (1) the spiked roller; (2) hopper feed.

Balk (*Eng., Carp., etc.*) A log of timber roughly squared up by the axe.

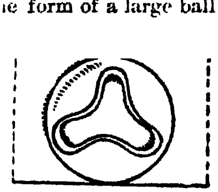
Ball (*Metallurgy*). The mass of spongy wrought iron collected from the puddling furnace (*q.v.*) ready for hammering to expel slag and consolidate the iron.

Ballast (*Eng.*) The loose material laid on the surface of a permanent way (*q.v.*) to steady the sleepers and to help the drainage of the line. Usually broken slag, cinder, stone, etc., of a depth of 18 in. Also the material placed in empty cargo vessels to sink the hull to a depth necessary to ensure stability.

Ball Bearings (*Cycles, Cars, etc.*) Any bearing in which the bearing surfaces are separated by small hardened steel spheres, turned very true. Frequently the bearing surfaces form a hollow and a solid cone with the balls between them; or the balls run in a channel of hemispherical section termed a "ball race." *See also* CYCLES.

Balled Warp (*Cotton Weaving*). A warp or number of threads coiled in the form of a large ball for easy transit and handling.

Ball Flower (*Architect.*) A small ornament of spherical shape used at intervals in a hollow moulding. It was used freely in Decorated Gothic work, and occasionally in the Early English period.



BALL FLOWER.

Balling, Balling Up (*Metallurgy*). The formation of the ball of puddled iron (*q.v.*)

Ballistic Pendulum (*Phys., Mechanics*). A heavy pendulum, with a bob adapted to receive and retain a projectile fired into it. By observing the vertical distance the bob rises, and knowing its weight we obtain the kinetic energy of the projectile, and hence its velocity at the moment of impact. A modified form of ballistic pendulum is also used for experiments on falling bodies.

Ball Joint (*Eng.*) A joint in which one member forms a part of a sphere fitting a corresponding hollow in the other; it allows play in all directions except along the axis of the two members.

Ballooning (*Cotton Spinning*). A defect in ring spinning caused by the high velocity of the ring traveller. This has the effect of causing the spun thread to fly outwards as it winds round the bobbin. Guards are fixed to counteract this, of which there are several kinds.

—— (*Eng.*) The lifting of the sediment in a steam boiler by the action of the steam.

Ball Pane. *See* HAMMERS.

Ball Race. *See* BALL BEARINGS.

Ball Valve (*Eng.*) A valve in the form of a sphere. It can turn round in its seat, thus securing more uniform wear.

—— (*Plumb.*) A cock used for supplying water to cisterns, governed by a hollow ball, fixed to the end of a lever. As the water rises above a given level, the ball raises the lever and closes the tap, the falling of the water level opening it again. The cistern is thus kept filled to a constant level.

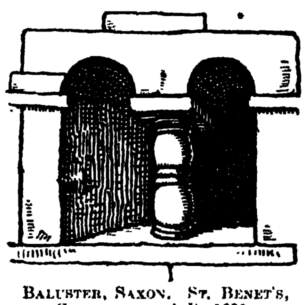
Balsam of Peru. *Toluifera* (*Myroxylon*) *pereiræ* (order, *Leguminosæ*). An exudation from the stem after removal of the bark. Used medicinally. *See also* BALSAMS.

Balsam of Tolu. *Toluifera* (*Myroxylon*) *punctata* (order, *Leguminosæ*). A balsam obtained by incision of the bark. It is used in medicine. *See also* BALSAMS.

Balsams. Exudations from certain plants; they contain benzoic or cinnamic acid or both, a volatile oil, generally a benzoic or cinnamic ester, and a resin. Most important balsams are gum benzoin, containing much benzoic acid (*q.v.*), Balsam of Peru, Balsam of Tolu, and Storax, which contains Styrene, $C_6H_5CH : CH_2$. They are reddish-brown solid or semi-solid substances, insoluble in water, but soluble in alcohol.

Balteus, *pl.* **Baltea** (*Cost.*) The shoulder belt used by the Romans, and from which hung the sword along the left hip.

Baluster (*Architect.*) (1) A kind of small column used in a series, with a capping, to form a protective fence. (2) A roughly formed mid-wall shaft used in belfry windows in Saxon architecture. (3) The return part of the Ionic volute. *See* ANGLO-SAXON *and* BOLSTER.



BALUSTER, SAXON. ST. BENET'S, CAMBRIDGE. A.D. 1000.

—— (*Carp.*) A slender column supporting the handrail and connecting it with the stairs or landing.

Balustrade (*Architect.*) A series of balusters, upon which a capping rests, either forming a protecting fence or employed merely as an ornament.

—— (*Carp. and Join.*) A row of balusters capped by a handrail.

Bambocciata (*Paint.*) A representation of rustic or grotesque scenes not always of the highest order. Bamboccio (a dolt) was the nickname of Pier van Laer, who painted many of these scenes. Teniers and Van Ostade have also painted similar pictures.

Bamboo. *Bambusa* (order, *Gramineæ*). This extensive genus of giant grasses has many economic uses, particularly in the East, where they furnish material for building and for every domestic use.

Bamboo Frames (*Cycles*). Bamboo rods have been used to replace metal tubes in cycle frames, for the sake of lightness, but are not likely to become general. The lugs are sometimes made of aluminium.

Banana. *Musa sapientum* (order, *Musaceæ*). The seedless fruits of one of the most valuable food plants known. The fibres of the stem and leaf stalks are used for cordage.

Banca Tin *or* **Straits Tin** (*Met.*) A pure ore from Malacca and Banca; the best tin found.

Band (*Architect.*) A flat member or moulding larger than a fillet, but smaller than a fascia. In Gothic architecture, a flat moulding or a series of ornaments forming a string course.

—— (*Cost.*) The collar which succeeded the uncomfortable ruff. It still survives as part of a conventional dress, whether academical, ecclesiastical, or legal, and is now termed bands. "Band-box" was formerly the light box in which bands were kept.

—— (*Eng., etc.*) A flat driving belt; also applied to any thin strap of metal or other material fixed round the circumference of an object.

Band Brake (*Eng., Motor Cars, etc.*) A band of steel (sometimes with wood blocks along its inner side) fitting round a drum on the shaft; one end is fixed to the frame of the machine, the other to a lever by which it can be drawn tightly round the drum to check its rotation. Band brakes are much used on motor cars.

Banded (*Her.*) When the tie or fillet which binds a sheaf of corn or arrows is of a different tincture from the sheaf, the sheaf is said to be "banded of that tincture."

Banded Structure (*Geol.*) This term is merely descriptive of an appearance in the rock under notice which is due to a parallel arrangement of layers of different character. It is, however, coming into use in a more restricted sense, as descriptive of the parallel structures observable in gneisses, which are due to alternate folia of different mineral composition.

Banderolle, Banner Roll (*Her, etc.*) (1) The small streamer which hung from the crook of a crosier, and was generally wound round the staff; (2) flags about 3 ft. square carried at funerals; (3) long bands used in scrollwork, etc.; (4) the streamers from a lance.

Bandoleer *or* **Bandolier** (*Cost.*) A shoulder belt with loops in which cartridges are carried.

Bands (*Bind.*) The cords to which the sheets of a volume are sewn. In *flexible* sewing the bands appear in the back, but when the sewing is so executed that the cords are imbedded in the back, the appearance of raised bands is obtained by glueing strips of leather across the back before binding.

—— *See* BAND (*Cost.*)

Band Saw (*Carp., Eng.*) A thin, flexible, ribbon-like saw, with its ends brazed together, and driven over revolving pulleys, between which is a table for the work, with a slit for the saw. Used chiefly for wood, but sometimes for metal.

Banjo. *See* MUSICAL INSTRUMENTS: STRING.

Banjo Frame (*Eng.*) A short connecting rod made of several bars joined in a kite-shaped frame.

Bank (*Typog.*) A table or bench on which sheets are placed as printed.

Banker (*Building*). A mason's or plasterer's bench.

Banking of Cycle Tracks (*Cycles*). The raising of the outer edge of a bend in the track to counteract the centrifugal force, which would otherwise carry the machine off the track when trying to turn round a bend.

Banking Up (*Eng.*) Covering a bright fire in a boiler with a closely beaten mass of small coal, to secure slow combustion when little or no steam has to be produced.

Banner (*Her.*) A large flag, square in shape, on which was a coat of arms or device. One edge was attached either to the staff or to a rod pendant from the top of the staff.

Baptistery (*Architect.*) A building, or part of a building, in which the rite of baptism is or was administered. In Early Christian churches the baptistery was a separate building kept quite distinct from the basilica (*q.v.*)

Bar (*Eng., etc.*) Usually a rod of metal of various forms of cross section. Also applied to many parts of finished structures or machines.

—— (*Her.*) A diminutive of the fesse; it only occupies one-fifth of the field. It is horizontal.

—— (*Lace Manufacture*). A term applied to most of the longer parts of a lace machine, but when used without a prefix generally means the steel or guide bars—thin ribbons of steel with holes or perforations at certain accurate intervals.

—— (*Marine*). A bank or ridge across the mouth of a harbour or inlet; not necessarily reaching the surface at any point, but sufficiently near to impede navigation.

—— (*Music*). (1) A perpendicular line drawn across the stave, immediately before the strong accent; (2) a measure of music contained between two perpendicular lines across the stave.

Bar Armature (*Elect. Eng.*) A large armature in which the windings are built up of copper bars instead of continuous wire, which would have to be of too large a size to be convenient. The connections to the commutator and between different bars are made by copper strips of suitable shape, attached to the bars by well made soldered joints. In the case of alternating current motors the rotating portion is often constructed in a somewhat similar manner, but the connections between the ends of the bars are much simpler. *See* MONOPHASE *and* POLYPHASE MOTORS.

Barbadoes Tar *or* **Jew's Pitch.** The mineral pitch imported from Barbadoes; from it is made black varnish. *See also* BITUMENS.

Barbe (*Cost.*) Piece of white plaited linen passing either over or under the chin, according to the rank of the lady wearing it. Was generally worn by widows, and still worn by nuns.

Barbotine (*Pot.*) Kaolin clay worked into a paste or slip from which objects can be moulded. Used for the decoration of pottery. Sometimes used for the vases, etc., so ornamented.

Barded (*Her.*) A horse covered with armour is said to be "barded."

Bare (*Eng.*) A term somewhat loosely used to indicate a dimension somewhat smaller than its nominal size; the expression should be avoided when possible.

Bareface Tenon (*Carp. and Join.*) A tenon with shoulder on one side only. *See* TENON.

Barff's Process (*Eng.*) Iron protected from ordinary red rust by heating to redness and exposing it to steam, thus producing a coat of the so-called magnetic oxide of iron, Fe_3O_4.

Barge Boards (*Carp.*) The boards fixed at the gable end of a roof, forming a lining between the roofing material proper and the interior.

Barge Course (*Building*). The row of tiles or slates over the gable.

Baritone (*Music*). (1) A male voice between a bass and tenor; (2) a brass instrument. *See* MUSICAL INSTRUMENTS: SAXHORN.

Barium, Ba. Atomic weight, 137·4. A silvery white metal which rapidly oxidises in air and decomposes water. To obtain it a solution of barium chloride is electrolysed with a mercury kathode, and the barium amalgam so obtained is heated in a porcelain tube by means of a platinum wire kept at a temperature of about 1150° by an electric current. The mercury volatilises first, and then the barium, which is nearly pure. Barium does not occur native, but in combination it exists in many minerals—*e.g.* BARYTES, WITHERITE, BARYTO CALCITE, ALSTONITE (*q.v.*), etc., etc.

Barium Compounds. BARIUM OXIDES, BaO, obtained by carefully heating the nitrate, is a white solid having the properties of a typical basic oxide (*see* OXIDES). Combines with evolution of much heat with water to form BARIUM HYDROXIDE, $Ba(OH)_2$, a white powder more soluble in water than slaked lime; the solution is called BARYTA WATER. BARIUM DIOXIDE, BaO_2, is produced by heating the monoxide in air or oxygen. It is a typical peroxide (*see* OXIDES *and* BRIN'S PROCESS). BARIUM SULPHATE, $BaSO_4$, is an insoluble white powder, and the chief source of barium compounds. Heated with charcoal it forms BARIUM SULPHIDE, BaS, a white solid which dissolves in dilute acids, forming the corresponding salt and sulphuretted hydrogen (*see also* BOLOGNIAN PHOSPHORUS, BARYTES, *and* BLANC FIXE). BARIUM CHLORIDE, $BaCl_2 2H_2O$, a white crystalline solid which may be obtained from the sulphate as indicated above; its solution is used as a test for soluble sulphates, which form with it the insoluble barium sulphate. BARIUM NITRATE, $Ba(NO_3)_2$, a white crystalline solid used in making "green fire," and also as a test for sulphate; may be obtained from the sulphate as indicated above. The soluble barium compounds are poisonous. *See also* BARYTES.

Bark (*Botany*). The dead tissue formed on the outside of the cork cambium. It often contains waste products, alkaloids, tannin, resins, etc., and consequently is of great economic value.

Bar Lathe (*Eng.*) A small lathe whose bed consists of a single bar of triangular or rectangular section.

Barley. *Hordeum vulgare* (order, *Gramineæ*). Several varieties of the species are cultivated; the two-rowed barley is the most common, while the six-rowed variety (known as *Bere* or *Bigg*) is more grown in Scotland. The hardiest is the four-rowed barley. Barley grain consists of four envelopes. The presence or absence of the husk determines the commercial preparations. Barley meal is prepared from the whole grain; pearl barley (which is used in making barley water), Scotch and milled barley are deprived of the husks. Cakes made from barley are found to be of less nutritive value than those made from wheat.

Barlow's Wheel (*Elect.*) A copper disc pivoted between the poles of a permanent magnet. If a current be caused to flow along a radius of the disc, the latter rotates; if the disc be rotated by mechanical means, a current is set up. The instrument thus acts either as a motor or a dynamo. The plane of the wheel and the direction of the current are at right angles to the plane of the magnet; thus the lines of force, the current, and the direction of motion are mutually at right angles.

Barmen Machine (*Lace Manufac.*) So named from "Barmen" in Germany, where it is principally made. It is a development of the "dolly" or braiding machine, and produces a clever imitation of "Torchon" lace. In its latest improved form the production can scarcely be distinguished from the "real" article. Manufacturing centres, Barmen and Nottingham.

Bar Mill (*Eng.*) Rolling mill for producing bars of iron or steel.

Barograph (*Phys., etc.*) An instrument for continuously recording the height of the barometer. In the simplest form the levers of an aneroid (*see* BAROMETERS) mark the height of the barometer (*i.e.* the atmospheric pressure) upon a rotating drum; when a mercurial barometer is used, a strip of sensitised paper may be drawn slowly past the top of the mercury, and a line will be left showing the boundary of the shadow which marked the height of the mercurial column at each instant.

Barometer. A barometer is an instrument used for measuring the pressure of the air. The simplest form is shown in fig. 1. It consists of a vertical tube something over 30 in. high, closed at the top. This is filled with mercury and inverted with its open end under the surface of mercury contained in a shallow vessel, A. The mercury in the tube falls to a height AB, which is usually between 28 and 30 in., according to the pressure of the air. The space above B in a properly constructed barometer is a very perfect vacuum, and is usually termed the Torricellian Vacuum, after its discoverer. A more convenient form of barometer consists of a tube bent into the form shown in fig. 2, termed the Syphon Barometer. The tube is first completely filled with mercury and then placed in a vertical position, the superfluous mercury being allowed to flow out at D. The vertical height between the levels of the mercury at A and B is in this case the height of the barometer. It is necessary to note that in this case a fall of half an inch at B will be accompanied by a rise of half an inch at A, and therefore the total height will have been diminished by 1 in. If, then, a fixed scale is attached to the longer tube, it will have to be divided into half inches, and each half inch numbered as if it were 1 in. In many cases a small float rests on the surface of the mercury at A, and a cord attached to this float turns a revolving pointer, which indicates the height of the barometer on a graduated dial. For accurate work a modified form of the cistern barometer devised by Fortin is frequently used. In this barometer the level of the mercury in the cistern is first adjusted to a constant level. The means of doing this are shown in fig. 3. The barometer tube A passes into a cistern (B), of which the upper part is of glass. The mercury in this cistern is retained by a false bottom, formed by a flexible sheet of leather (C), attached to a ring (F). This flexible bottom can be moved up and down by a set screw (D), which passes out at the bottom of the cistern. The level of the mercury in the cistern is raised or lowered by turning the screw D until an ivory point E exactly touches the surface. When this is the case a fixed scale on the tube A gives the exact height of the mercury in the tube above the level of the mercury in the cistern. The mercurial barometer is not suited for any purpose where portability is required, and a different principle is used in what is called the "Aneroid" barometer. This principle is illustrated diagrammatically in fig. 4. A shallow metal vessel (A) is closed by a thin corrugated top of flexible metal (B), and is exhausted of air. An increase in the pressure of the air will compress the flexible top B inwards, and a diminution in the pressure will cause it to spring out. The movements of B are rendered visible by means of a lever (D) attached to its centre in the manner shown in the diagram.—CORRECTIONS OF THE BAROMETER READING: Both the mercury in the barometer and the material of which the scale is composed are liable to expansion and contraction by changes in the temperature of the air, and for this reason readings are reduced to their value at 0° C. in the case of accurate observations. The following formula for reducing the observations is proved in works on heat:

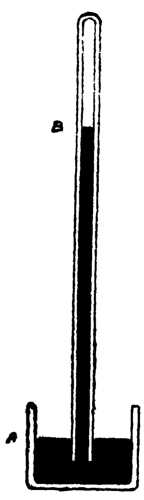


FIG. 1. SIMPLE F.

FIG. 2. SYPHON BAROMETER.

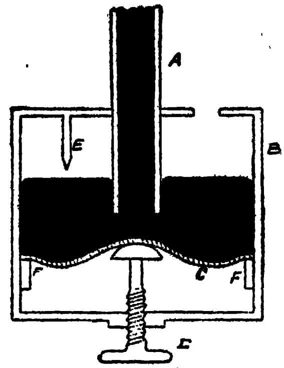

FIG. 3.—FORTIN'S BAROMETER (CISTERN ONLY).

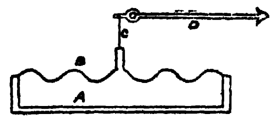

FIG. 4.—ANEROID.

H = the true height of a barometer at 0°.
h_t = the observed height at a temperature t.
δ = the coefficient of cubical expansion of mercury.
α = the coefficient of linear expansion of the material of the scale.

Then

$$H = h_t \left\{ 1 - (\delta - \alpha)\, t \right\}.$$

For a barometer with a brass scale, taking the usual values of α and δ, this formula becomes

$$H = h\ (1 - {\cdot}000162t).$$

Barometer Corrections (*Phys.*) *See* BAROMETER

Barometer, Mercurial (*Phys.*) *See* BAROMETER.

Baroque (*Art.*) Ornamentation that is grotesque or in bad form.

—— (*Architect.*) *See* RENAISSANCE ARCHITECTURE.

Barrathea (*Woollen Manufac.*) Small fancy weave of a broken mat type applied to dress and coating fabrics of this name.

Barrel (*Building*). (1) Iron piping used for gas or water; (2) the cylinder in which the piston of a pump works.

—— (*Eng., etc.*) The cylindrical part of many structures—*e.g.* the body of a pump, locomotive boiler, rifle, or gun. Also the part of a machine on which a rope or chain is wound, either on the surface or in specially cut grooves.

—— (*Watches*). The cylindrical box containing the mainspring.

Barrel Vault (*Architect.*) A vault of semicircular cross section. It is the simplest kind of vault used to cover a rectangular space. It was used by the Romans and also by the Romanesque architects.

Barrier Pillars (*Mining*). The largest pillars left to support the roof in a mine.

Barrow (*Archæol.*) An artificial hillock or mound heaped over the graves of presumably notable individuals in prehistoric times.

Barrulet (*Her.*) Is one-fourth the width of the *bar*, and occupies one-twentieth of the field.

Barruly (*Her.*) Said of a shield traversed by more than eight bars.

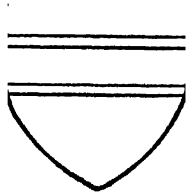
Barry (*Her.*) A shield divided into an even number of bars.

Barry Bendy (*Her.*) The lines dividing the shield are drawn both barwise and bendwise.

Barry Pily (*Her.*) The lines are drawn barwise (*i.e.* horizontally), and then divided into an equal number of piles or wedge-shaped pieces of alternate tinctures.

Barry Wavy (*Her.*) When the horizontal lines are wavy and not straight.

Bars Gemelles (*Her.*) Barrulets in couples.



BARS GEMELLES.

Bar Solder (*Plumb.*) Plumbers' solder, composed of two parts of lead to one of tin, cast in the form of bars, and used for wiping joints.

Bar Stays (*Eng.*) Rods used to strengthen a boiler; so called to distinguish them from stays which are also tubes, through which water circulates.

Bar Timbering (*Mining*). Supports for the roof of a level, etc., while the material below is excavated and the permanent supports (masonry, etc.) are being put in.

Bartizan (*Architect.*) A small turret projecting beyond the face of the main building.

Bartonian Series (*Geol.*) A name used for the MIDDLE EOCENE strata of the same age as the fossiliferous clay seen in the coast at Barton, in Hampshire. This is a marine deposit containing an abundant suite of fossils, chiefly of types analogous to those animals which at the present day frequent the seas of sub-tropical regions.

Bar Tracery (*Architect.*) The form of window tracery used in Gothic work after the early part of the Decorated period. In this kind of tracery the mullions are carried up into the head of the window, and have the appearance of having been bent to the required shape. *See* TRACERY, PLATE TRACERY, *and* FLAMBOYANT TRACERY.

Bar Trees (*Woollen Manufac.*). *See* WOOF.

Baryta. A common name for barium monoxide. When the latter is shaken with water the solution of barium hydroxide so obtained is called baryta water.

Barytes (*Min.*) Barium sulphate, $BaSO_4$; baryta = 65·7; sulphuric acid = 34·3 per cent. It crystallises in a great variety of forms of the rhombic system. It is one of the most insoluble minerals; colourless or variously tinted. It is used largely in the manufacture of permanent white and for admixture with white lead and in the manufacture of paper for process printing. For these purposes pure barytes is in much demand. When stained by ferric hydrate, the mineral has to be treated with sulphuric acid before crushing. It is an important gangue metal, often being found in lead-bearing veins. Some of the best known localities are Silvera Band Mine near Milburn, Rundale Mines near Dufton in Westmorland, Whitehaven in Cumberland, Wanlockhead in Dumfriesshire, etc.

Baryto Calcite (*Min.*) A combination of the carbonates of calcium and barium crystallising in monosymmetric prisms. $BaCO_3 . CaCO_3$. barium carbonate = 66·3; calcium carbonate = 33·7 per cent. Usually white or pale yellow. Found near Nenthead on Alston Moor, and at Wall, near Hexham.

Basal (*Min.*) A term used to designate a plane parallel to or coincident with a face normal (or at right angles) to the principal axis of a crystal. Thus the basal cleavage of barytes is a cleavage parallel to the basal face, which is itself normal to the principal axis.

Basalt (*Geol.*) A hemicrystalline rock of basic composition which contains, besides the glassy or lithoidal ground mass, crystals of a lime soda felspar (which is usually Labradorite), AUGITE (or some other pyroxene), OLIVINE, and ILMENITE. It forms lavas and also dykes and sills. It is usually a dark-coloured, heavy rock, which weathers with a more or less ferruginous crust.

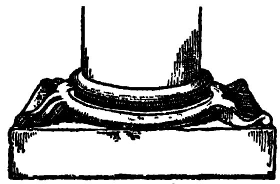
—— (*Archæol.*) This stone was used by the Egyptians for sculpture and building. *See also* BUILDING STONES.

Basalt Glass *or* **Tachylite** (*Geol.*) A somewhat rare native glass of basic composition, corresponding to the PITCHSTONES amongst the rocks of intermediate composition and to the OBSIDIANS in the acid series. The glass is due to the rapid cooling of the magma from which the basalt arises, generally where it comes into contact with the colder surface of the rock adjacent. It appears to devitrify more rapidly than the other native glasses.

Bascinet, Basinet, Basnet (*Armour*). A helmet, somewhat globular in shape, but terminating in a point, worn during the Camail period. It was fastened by a lace passing through the edge of the helmet and protected by plates of metal. It had no visor at first, the "heaume" being worn over it for battle and at jousts.

Bascule Bridge (*Civil Eng.*) A swing bridge of the "seesaw" type. The Tower Bridge, in London, is one of the best examples.

Base (*Architect.*) (1) The lower portion of a pier or wall. (2) That part of a column on which the shaft rests. In the Greek-Doric order no base is used, however, the shaft resting directly on the stylobate.



BASE, EARLY ENGLISH.

—— (*Dec.*) The material which is mixed with the oil to give body to paints. The most common bases are white lead, red lead, zinc white, and oxide of iron.

Base Line (*Surveying*). (1) An accurately measured line from which a triangulation is started or offsets are measured. (2) The main lines of a traverse (*q.v.*)

Base Moulding (*Architect.*) A moulding near the base of a wall, either just at the top of the plinth or a short distance above it.

Base Plate (*Eng., etc.*) The lowest part of a machine; a structure to which the remaining parts are directly or indirectly fixed. In large machines it is usually an iron casting with suitable projections, to which the superincumbent portions of the structure can be fixed.

Basic Dyes. Dyes which in order to fix them upon a fabric are required to be combined with a substance of acid character; *e.g.* rosaniline will dye cotton when tannic acid is used as mordant, but it will dye wool or silk directly, probably because wool and silk contain some acid as a constituent of their fibres. *See also* DYES AND DYEING.

Basicity. A term used to express the number of hydrogen atoms in the molecule of an acid that can be replaced *by metals.* A *monobasic acid* has one replaceable hydrogen atom, a *dibasic acid* has two, and so on; *e.g.* nitric acid has one replaceable hydrogen atom, and is monobasic; citric acid, $C_6H_8O_7$, has three replaceable hydrogen atoms, and is tribasic.

—— (*Met.*) The power of acting as a "base" in the chemical sense. In metallurgy it refers especially to the absence of silica, which has the opposite or "acid" character.

Basic Lavas (*Geol.*) Rocks which have been poured out at the surface from volcanic orifices, and which contain a low percentage of silica—generally less than 50. They include rocks of somewhat varied composition and character, of which ordinary basalt may be regarded as a central type.

Basic Oxide. *See* OXIDES.

Basic Process (*Metallurgy*). An improvement of the Bessemer steel process (*q.v.*) in which the converter is lined with magnesian limestone or dolomite, a material nearly free from silica. This removes the phosphorus and silica, which are very detrimental to the iron even in small quantities, and, moreover, yields a "basic slag" rich in phosphorus, and of considerable value in agriculture for enriching soil, as phosphates are essential to the proper growth of most plants.

Basic Salt. A normal salt (*see* SALTS) combined with the basic oxide corresponding to it; *e.g.* basic lead acetate is $PbO.Pb(C_2H_3O_2)_2$; basic bismuth nitrate is $BiONO_3$, which may be regarded as $Bi_2O_3 . Bi(NO_3)_3 = 3(BiONO_3)$.

Basic Steel (*Met.*) Steel produced by the basic process (*q.v.*)

Basilica (*Architect.*) The Roman name for a hall, either of justice or in which business was conducted. Roman basilicas were in many cases adapted for use as Christian churches, and the new Early Christian churches were built on similar lines. The basilica generally consisted of a nave with aisles, galleries over the aisles, and a semicircular apse at one end. The term basilica was originally used to denote a king's palace. *See* APSE, NAVE, *and* AISLES.

Basilidian Gems. *See* ABRAXAS.

Basilisk (*Archæol.*) A mythical reptile, also termed cockatrice, hatched by a serpent from a cock's egg. Its breath and its gaze were alike fatal. Symbolical of the spirit of evil.

—— A large brass cannon, formerly in use, throwing a shot of about 200 lb.

Basin (*Civil Eng.*) An enclosure or dock with quays, into which vessels can be admitted at high tide, the water being then retained at the same level by dock gates. Used for loading and discharging ships.

—— (*Geol.*) A SYNCLINAL (*q.v.*)

Basket (*Eng., etc.*) A strainer attached to the foot pipe of pumps to exclude solid bodies. Also applied to the aggregate of parallel rods in certain type-writing machines, and to devices of similar appearance in other machines.

Basking Shark. *Cetorhinus maximus* (family, *Carchariidæ*). A large shark found in the North Atlantic, and hunted for the sake of the oil extracted from its liver (shark oil).

Bas Relief *or* **Basso Relievo** (*Architect.*) Sculpture in which the figures project less than half their proper proportion from the background. One of the finest examples is the frieze on the cella of the Parthenon, of which a considerable portion is now in the British Museum among the Elgin marbles. *See* ALTO RELIEVO, MEZZO RELIEVO, CAVO RELIEVO, *and* INTAGLIO.

Bass (*Botany*). *Leopoldinia piassaba* (order, *Palmæ*). The persistent leaf bases end in tufts of bristle-like fibres, which constitute the bass or *piassaba* fibre used in making bass brooms. The bass from Bahia is obtained from another palm (*Attalea funifera*). *See also* WOODS.

—— (*Music*). (1) The lowest of men's voices. (2) The lower series of sounds. (3) The lowest note of a chord.

Bass Drum. *See* MUSICAL INSTRUMENTS: PERCUSSION, INDEFINITE SOUND.

Bassoon. *See* MUSICAL INSTRUMENTS: WIND, WOOD.

Bass Tuba. *See* MUSICAL INSTRUMENTS: WIND, BRASS.

Bass Wood. *See* WOODS.

Bast (*Botany*). The soft bast or phloem is the tissue on the outer face of the wood of a vascular bundle; it consists of sieve tubes (*q.v.*) and other elements.

Bastard Cop (*Cotton Spinning*). *See* COP.

Bastard Cut (*Eng.*) A coarse file, slightly finer than the most coarse kind.

Bastard Flatting (*Dec.*) Painted work finished only with a slight gloss, produced by using less oil and more turpentine than is employed in ordinary

oil paint. Three-fourths turpentine and one-fourth boiled oil is the proportion often employed. Also termed "eggshell gloss." Bastard flatting makes a good ground for work that is to be finished in varnish or enamel.

Bastard Founts (*Typog.*) Type cast on a body larger or smaller than is usual.

Bastard Thread (*Eng.*) An old expression for a screw not of standard pitch.

Bastard Title (*Typog.*) An abbreviated or half-title on a page preceding the full title page of a book.

Bastard Tuck (*Building*). The name given to POINTING (*q.v.*) when a small projection of the stopping itself is formed on the joint.

Basterna (*Archæol.*) A mule litter used chiefly by ladies during the period of the Roman Empire.

Bast Fibres (*Botany*). The term is applied to strands of lignified fibres (belonging to the pericycle) on the outside of a vascular bundle. The fibres usually have a tensile strength equal to that of the best wrought iron or hammered steel, while their ductility is ten times as great as that of iron.

Bat (*Building*). Half a brick—*i.e.* a piece $4\frac{1}{2}$ in. long.

Batement Light (*Architect.*) A window having vertical jambs and mullions and a sloping sill.

Bath (*Eng., etc.*) A vessel containing liquid, frequently liquid metal. Also applied to the liquid itself, or even to the process of dipping some object in course of manufacture into the liquid.

Bathing (*Hygiene*). Is of hygienic importance. The skin should be kept thoroughly clean, otherwise dead epidermic cells collect, and prevent the proper physiological action of the glands in the skin, thereby throwing extra work on the kidneys and lungs. A bath is best taken in the early morning. It should never be taken immediately after a full meal.

Bath Stone. *See* BUILDING STONES.

Baths, Waste from (*Hygiene*). It is of great importance that the waste-pipes from baths should not be connected with the drains. They should be efficiently trapped, and be made to discharge into a properly trapped gully. The overflow pipe should discharge into the open air. Baths should not be cased in, as this form of fixing accumulates dust.

Bating (*Leather Manufac.*) A bate consists of a fermenting solution of hen or pigeon excrement into which light skins for "dressing" leather are placed to soften and remove lime. The action is largely bacteriological. The process is being gradually superseded by safer and less objectionable methods.

Baton (*Her.*) A diminutive of the bend sinister, of which it is one-fourth the width, and couped at the ends—*i.e.* not touching the edges of the shield. It is used as an abatement, and is generally known as the bar sinister.

—— (*Music*). The conductor's stick for beating time.

Bat's Wing (*Gas Fitting*). A gas burner with a slit giving a flat flame.

Batten (*Carp.*) A piece of wood from 2 to 7 in. wide and up to $2\frac{1}{2}$ in. thick.

—— (*Woollen Manufac.*) French term for going past the portion of the loom for carrying the reed or sley and shuttle race, and for beating "home" the weft yarn. Also applied to the frame mounted with the card cylinder in the Jacquard loom.

Batten Door (*Carp. and Join.*) A door having vertical boards about 3 in. wide in the place of panels. They may be ledged only, or ledged and braced.

Battened Wall (*Carp.*) A wall having pieces of wood (battens) fixed to it to nail matchboarding to, etc.

Batten Lay or Lathe (*Silk Manufac.*) A wooden frame swinging from the loom top, carrying the reed and beating up the weft after each pick. The fly batten has shuttle boxes at each end of the shuttle race, and in a power loom works on a shaft below the warp.

Batter (*Building*). A wall out of perpendicular. Chimney shafts "batter," or slope, about $2\frac{1}{2}$ in. in every 10 ft. of their height.

—— (*Typog.*) Broken or damaged type.

Battery (*Elect.*) (1) A number of primary or secondary cells, condensers, Leyden jars, etc., acting together; (2) often applied, incorrectly, to a single cell. *See* CELLS (PRIMARY) *and* ACCUMULATORS.

—— (*Eng.*) A collection of machines or other plant of a similar character—*e.g.* a number of boilers in the same set, or a number of ore-crushing stamps at a mine.

—— (*Mining*). A bulk head of timber in a gallery or horizontal passage in a mine.

Battle Axe (*Archæol.*) A war weapon varying in shape, size, and material from the stone axe of prehistoric times to the halberd, which was discontinued in the fifteenth century. The axe with an edge on one side and a point on the other was called a pole axe. The axe was the chief weapon of the early Britons.

Battlement (*Architect.*) A parapet used in Gothic work, formed with a series of openings or embrasures, separated by rising parts called merlons. It was originally intended for purposes of defence, but was afterwards constructed as an ornamental feature.

Battle Piece (*Art*). A picture or sculpture representing a scene on a field of battle.

Baudekyn (*Cost.*) A rich material woven from gold thread and silk.

Baumann-Schotten or Schotten-Baumann Reaction. A reaction for the recognition of the amino group ($-NH_2$), imido group ($=NH$), or the hydroxyl group ($-OH$) in organic compounds. A little benzoyl chloride (*q.v.*) is added to the substance, then caustic potash solution till faintly alkaline, and so on till the reaction is completed, gently heating if necessary. In this way a benzoyl derivative is formed—*e.g.* phenol would give $C_6H_5 . OOC . C_6H_5$, phenyl benzoate.

Bauxite (*Min., Met., etc.*) Usually written BEAUXITE (*q.v.*) by mineralogists. Very refractory bricks and slabs for lining furnaces are made by mixing crushed calcined bauxite with clay, or sometimes with graphite.

Bay (*Carp., etc.*) A ceiling or roof divided into panels.

—— (*Eng.*) The spaces in a structure between adjoining stays or struts—*e.g.* the large openings in a lattice girder.

Bayeux Tapestry (*Art*). The well known roll of linen, 200 ft. long by 20 in. wide, preserved at the Town House, Bayeux. It is worked in worsted, and seven colours are used. It depicts fifty-eight scenes in the life of William I.

Bay Salt. Common salt crystallised by slow evaporation. It is a coarse-grained salt, used for curing meat of various kinds.

Bay Window (*Carp. and Join.*) Usually constructed of three lights, which may be "squint" when the sidelights make an obtuse angle with the front, or square when they are at right angles.

Beacon (*Marine*). Any small form of lighthouse constructed on minor shoals. Also a general term for a signal, signal-light, prominent landmark, etc.

Bead (*Architect.*) A small circular moulding. When carved, it usually resembles a string of beads. *See* ASTRAGAL *and* TORUS.

Bead *or* **Beading** (*Carp., etc.*) A linear ornament of uniform cross section used very much in woodwork; to a less extent in metal. Occasionally used to confer strength, but more often for appearance only.

Bead Butt (*Carp. and Join.*) A flush panel with a bead on the vertical edges only.

Bead Flush (*Carp. and Join.*) A flush panel with a bead all round it.

Bead Router. An iron stock in which beading irons of various sizes are fixed. Used in forming a bead on circular work

Beads *or* **Bead Planes.** Planes for "sticking" beads or cutting them out of solid wood.

Bead Sleekers (*Moulding*). A tool used by moulders to finish off a bead in the mould.

Beaked (*Her.*) When the tincture of the beak is different from that of the body.

Beak Head (*Architect.*) An ornament used in Norman work. It was usually carved on the mouldings of a doorway, and took the form of a grotesque head with a beak. *See also* CAT'S HEAD.

BEAK HEAD.

Beak Iron, *or* **Beck Iron.** The conical projection of an anvil. Sometimes "Beckern."

Beam. A beam may be defined as a long bar of wood or metal supported at one or more points, and carrying a load either uniformly distributed or concentrated at various positions. The following terms are used in connection with beams: (1) DEFLECTION—denoted by "d." This is the greatest extent to which any point of the beam is bent by the load which it carries. The following terms are defined under their separate headings: (2) ELASTICITY, denoted by E; (3) BENDING MOMENT, denoted by M; (4) MOMENT OF INERTIA, denoted by I; (5) RADIUS OF CURVATURE, denoted by R; (6) STRESS, denoted by p; (7) NEUTRAL LAYER. If the material of a beam were divided up into thin horizontal layers, it would be found that the uppermost of the layers were in a state of compression, and the lowest layers in a state of tension. These stresses gradually diminish towards a layer of the material of the beam which is, in most cases, at or near the centre (its exact position depends upon the form of the cross-section of the beam; it runs through the "centre of gravity" of the cross-section). This layer is known as the "neutral layer." The distance of any point in the material of the beam above or below the neutral layer is denoted by the letter "y." The above quantities are in all cases connected by the following equation:

$$\frac{P}{y} = \frac{M}{I} = \frac{E}{R}$$

Making use of the equation just given, we are able to calculate the deflection of a beam under any given set of circumstances if we know its dimensions, and the value of the coefficient of electricity (E) for the material of which it is made. The two commonest cases are: (i) A beam of length "l" supported at the ends and carrying a load W at the centre

$$d = \frac{Wl^3}{48\,E\,I}$$

(ii) A beam of length supported at the ends and carrying a load W uniformly distributed over the beam:

$$d = \frac{5}{384} \times \frac{Wl^3}{E\,I}$$

The simplest beams are those of uniform rectangular section; these are most commonly made of wood. Beams of iron or steel are usually made of cross-section in the form of "H"; it is usual to term these iron beams "girders." If the beam is made of cast iron, the lower part, which is in tension, has to be larger than the top part, which is in compression, in order to secure uniform resistance to both stresses; but wrought iron or steel beams have the top and bottom parts the same size. Very large girders are built up of separate pieces at the top and bottom, connected by a central portion or "web," made either of sheets of metal or of numerous bars crossing one another at an angle. A fine example of the latter, known as a "Warren Girder," is to be seen in Charing-Cross railway bridge. The actual calculations involved in designing a beam or girder which is required to carry a given load are somewhat long and complex. They are usually carried out by means of formulæ based on the equations given above. These formulae are given in works on engineering and building construction and in the various pocket books for engineers and builders.

Beam (*Cotton-weaving, etc.*) A flanged roller, similar to a large bobbin, for coiling the warp round in a broad sheet. Used for beam-warper and the loom. *See* BEAMING.

Beam Compass. An instrument for describing circles too large for the ordinary drawing compasses. It consists of a straight bar, on which metal holders for the pencil and compass point can be fixed at right angles to the bar. These holders are called TRAMMELS.

Beam Engine (*Eng.*) A form of engine in which the piston rod was attached to a beam swinging on a central axis; to the other end was attached the pump rod, or connecting rod. Nearly obsolete, except for some pumping engines, but once universal, even being used for marine purposes. *See also* STEAM ENGINES.

Beam Filling (*Building*). The brickwork between the wall plate and the underside of the roof.

Beaming (*Cotton Weaving*). A process in coloured goods manufacture by which the ends that are warped are all run in one broad sheet in their particular pattern on to the weaver's beam. Sometimes adopted in grey manufacturing for running grey-balled warps on to the weaver's beam.

—— (*Woollen Manufac.*) The operation of winding the warp or chain on to the warp-roller or beam, so that each thread will be delivered regularly during weaving.

—— *or* **Turning On** (*Silk Manufac.*) The process of spreading and winding the warp on the cane or warp roll. The warp is placed round a large drum and divided into PORTEES or HALF PORTEES in the teeth of VATOE (*q.v.*); it is then wound on the cane roll, considerable tension being applied to the silk to cause it to pass on to the roll firmly and evenly.

Beams (*Lace Manufac.*) Long slender cylinders of tin plate, in length proportionate to the width of the lace machine. They are requisite where a variable length of material is being used up.

Beam Warping (*Cotton Weaving*). A system of preparing back beams for the SLASHER (*q.v.*) Each beam contains a standard number of threads of a certain length. Used principally for the grey trade.

Bean *or* **Shot Copper** (*Met.*) Copper granulated by pouring through a perforated vessel into water.

Beans. Order, *Leguminosæ*. *Vicia faba* is the broad bean; *Phaseolus vulgaris*, the French bean; *P. multiflorus*, the scarlet runner. Under the name haricots are placed various species of *Phaseolus*. Beans form a very important article of diet; they contain a large quantity of proteids and salts, and are therefore of great nutritive value. During growth and storage beans are attacked by a weevil (beetle), the larva of which may frequently be seen in the bean.

Bear (*Eng.*) A form of punching machine (*q.v.*)

—— (*Zoology*). Genus, *Ursus*; species, *Arctos* (North Europe), *Americanus* (America), *Maritimus*, the Polar bear. The skin affords a useful heavy fur; the flesh is edible, and the fat is frequently utilised as unguent for the hair.

Beard (*Typog.*) That part of the type above and below the face of the letter.

Bearers (*Carp.*) The fillets on which a shelf is fixed. The crosspieces carrying a gutter boarding.

Bearing (*Carp.*, *etc.*) The part of a girder which rests on the supports.

—— (*Eng.*) The support of a rotating shaft; the forms are chiefly distinguished from each other by the means used to diminish friction. *See* BALL BEARINGS, ROLLER BEARINGS, ETC.

—— (*Surveying*). The angle formed by a line with the direction of the magnetic needle.

Bearing Metals (*Eng.*) Alloys used to form the surface of a bearing where the friction occurs—*e.g.* Babbitt's metal, gunmetal, etc. (*q.v.*)

Bearing Piles (*Civil Eng.*) Piles (*q.v.*) driven into soft ground up to their heads, to support masonry or other structures.

Bearing Surface (*Eng.*) The part of a surface in contact with another object and supporting it; in particular, the part of a shaft and bearing which are in contact with each other.

Bearing-Up Stop (*Mining*). A partition used to lead air to a face where work is going on.

Bearing Walls. *See* ARCH.

Beasts, Heraldic. May be recognised at once by their conventional style. The heralds have pressed most animals into use as charges or supporters.

Beater (*Cotton Spinning*). An attachment to an opening or scutching machine, consisting of a shaft on which are fixed blades or wings for the purpose of shaking the cotton when being cleaned. There are several kinds—vertical, conical, porcupine, two-winged, and three-winged.

—— (*Paper Manufac.*) A machine for reducing pulp to a fine state of division.

Beater Roll (*Paper Manufac.*) A heavy iron roll fitted with long iron bars, which rotates in the beater, for disintegrating pulp.

Beating Up (*Cotton Weaving*). The third primary movement of a loom. The forcing or bumping up of weft after it is carried across through the warp by the shuttle. It is accomplished by the loom crank, sley, and reed.

Beats (*Music*). The pulsations of time in a bar, also called "pulses."

Beats (*Sound*). Maxima and minima in the composite sound produced by two notes whose frequencies do not differ by more than sixteen vibrations per second; this result is due to INTERFERENCE (*q.v.*) of the two sets of waves.

Beaumontage. Material used for filling up accidental holes in wood or metal work. In cabinet work, resin and beeswax with colouring matter; in pattern making, chalk and varnish; in iron work, sal ammoniac (ammonium chloride, NH_4Cl), mixed with iron borings, which rust into a solid mass, are used.

Beauxite (*Min.*) An impure aluminium hydrate, essentially $Al_2O_3 . 2H_2O$ with impurities of ferric oxide, phosphates, etc. It occurs in oolitic or clay-like deposits of whitish-brown or reddish-brown colour. From Beaux in France, the United States, Foyers in Scotland, etc. It is now the principal workable ore of aluminium.

Beaver (*Armour*). "In fourteenth century applied to the moveable faceguard of the bascinet (*q.v.*), otherwise called *viziere ventaile* or *avant-taile*. In the early part of the fifteenth century the beaver appears formed of overlapping plates, which can be raised or depressed to any degree desired by the wearer. In the sixteenth century it again became confounded with the vizor, and could be pushed up entirely over the top of the helmet, and drawn down at pleasure."—PLANCHÉ.

—— (*Zoology*). *Castor canadensis* (family, *Castoridæ*). The well known rodent is valued on account of its fur, flesh, and the substance CASTOREUM (*q.v.*)

Beaver Cloth (*Woollen Manufac.*) A thick woollen fabric covered with fibre or nap. The best qualities are made in the West of England; medium and lower qualities in the heavy woollen districts of Yorkshire.

Beaver Finish (*Woollen Manufac.*) A type of finish which gives to the fabric a soft fibrous surface, the fibres being laid, in the process of raising, in one direction. Originally the finish was an imitation of the fur of the beaver.

Bêche-de-Mer (*Zoology*). Class, *Holothuroidea*; sub-kingdom, *Echinodermata*. A group of wormlike marine animals allied to the starfishes. Certain species yield a Chinese food known as TREPANG.

Beck. *See* BEAK IRON.

Beckmann's Apparatus (*Heat.*) *See* FREEZING POINT.

Bed (*Building*). A layer of mortar put under a wall plate, stones, or bricks.

—— (*Typog.*) The level surface or table of a printing press in which the forme lies.

Bed Charge (*Met., Foundry*). The coke which forms the bottom layer in charging a cupola furnace.

Bedder (*Pot.*) A mould, generally made of plaster of Paris, used to impress upon ground flint the exact shape of the clay plate or saucer which is to rest thereon whilst being fired in the bisque oven.

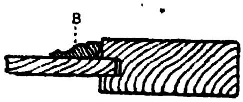
Bedding In (*Moulding*). Moulding by laying the pattern in the sand of the foundry floor and heaping the sand round it, instead of forming the mould in boxes full of sand.

Bedford Cord (*Cotton Manufac.*) A cloth ribbed longitudinally without floats on its surface, and firmly woven.

Bed Joints (*Build.*) (1) The radiating joints of an arch. (2) The horizontal joints of a wall.

Bed Mould (*Architect.*) The moulding immediately under the corona of a classical cornice.

Bed Moulding (*Carp.*) A moulding fixed just below the surface of the framing.



BED MOULDING.

Bed Plate (*Eng.*) *See* BASE PLATE.

Bed Plug (*Build.*) A dowel in the bed joint of a stone.

Bee (*Zoology*). *Apis mellifica* (family, *Apidæ*). The honey bee is well known as the source of honey and wax. *See* BEESWAX, HONEY.

Beech. *See* WOODS.

Beer. A beverage prepared by the fermentation of malt extract by yeast: hops (which contain a bitter principle—lupulin) are added to give the bitter flavour. In place of malt, starch and glucose (artificial) may be used, and in place of hops cheaper substitutes may be used, as quassia, gentian, wormwood. The percentage of alcohol varies from 2 (Berlin white beer) to 8·5 (Scotch ale). Arsenic may be present in beer when made from glucose prepared from starch by means of arsenic containing sulphuric acid. The adulterants of beer are water (which is often added to a considerable extent), salt, sulphuric acid, and liquorice.

—— (*Cotton Weaving*). A term used as a basis for reed counting—*i.e.* twenty dents, or splits, or forty ends, two ends per split. Sometimes a warp during the warping process will be split up into beers or bunches, so as to facilitate counting off. In other cases they are used to assist in spreading out the warp threads by passing through a wraithe during the beaming process. The Scotch name for the same is "porter."

—— (*Linen Manufac.*) "Beer" in Ireland and "porter" in Scotland are terms used in linen manufacture, and signify forty threads of warp. In some cases the fineness of the cloth is expressed by "beers" or "porters"; thus a 40-beer or 40-porter drill means a drill containing forty beers or porters in a set width of cloth—usually 30 in.

Bees (*Art, Archæol.*) The symbol of eloquence.

Beeswax. A secretion of glands in the body of the honey bee, used in the formation of the honeycomb. The wax is used in pharmacy for plasters and ointments. Consists chiefly of myricin (myricyl palmitate, $C_{15}H_{31}COO.C_{30}H_{61}$) and cerotic acid, $C_{27}H_{54}O_2$. Melts at 62° to 65°. Sp. gr. ·962.

Beeswaxing (*Eng., Dec., etc.*) (1) Covering an iron pattern with beeswax to make it more easy to withdraw from the sand of the mould. (2) A method of finishing hard wood furniture, fittings, and floors by rubbing with beeswax thinned with turpentine. It is often called WAX POLISHING. When applied to unwaxed surfaces, the beeswax is cut up in small pieces and digested in turpentine until a paste is produced. Sometimes a little carnauba wax (*q.v.*) is added, to render it firmer. The wax paste is applied by means of a brush. It is easy to apply, and keeps in good condition, while the cost is small. Two coats are given, and each is polished by means of rags or short stiff-bristled brushes. Success depends largely upon the amount of labour given, a light rubbing being useless. Oak and black walnut are the woods on which it is usually employed. On floors such as those of ballrooms the polish must be frequently renewed by sprinkling powdered wax upon the surface and briskly rubbing by means of brushes, which are sometimes attached to the feet of the operator.

Beetroot. *Beta vulgaris* (order, *Chenopodiaceæ*). A variety—the sugar beet—is extensively cultivated in Europe as a source of sugar.

Bel-Etage (*Architect.*) The main story of a building.

Bell (*Architect.*) The body of a Corinthian or Composite capital below the abacus, around which the foliage and volutes are arranged. The same name is also given to the corresponding part of a Gothic capital when its form is similar. *See* COLUMN.

Belladonna (*Botany*). *Atropa belladonna* (order, *Solanaceæ*). The fresh leaves, with or without the branches of the mature plant, and also the dried root, yield the alkaloid atropine, used in ophthalmic practice.

Bell Centre Punch (*Eng.*) A hollow cone, along the axis of which a pointed punch can slide, the point projecting to any suitable distance inside the cone. Used for marking the centre in the end of a round bar or other cylindrical object.

Bell Chuck (*Eng.*) A chuck (*q.v.*) with a cylindrical hollow, usually having set screws projecting into the hollow for holding small work in the lathe.

Bell Crank Lever (*Eng.*) A lever with two arms at right angles, and the fulcrum at the angle or apex.

Belled (*Her.*) Bearing a bell or bells, used of hawks and cows.

Belleville Boiler. *See* BOILERS.

Bell Gable (*Architect.*) A gable at the west end of a church carried up above the roof, and usually containing from one to three bells. It is used in small churches which have no towers.

Bell Metal (*Eng.*) A bronze (*q.v.*); usually copper 16, tin 5; hard and brittle. This alloy gives a strong sound when struck, hence its use for bells.

Bell Metal Ore (*Min.*) A synonym for STANNITE (*q.v.*)

Bells (*Sound*). Constructed of alloys resembling bronze which are found to possess sonorous properties. The modes of vibration and the over-

tones of bells are very complex, as may be readily heard on listening to a large bell at a short distance from it, when many tones can be heard in addition to the principal note.

Bell Traps (*Hygiene*). Under the Drainage by-laws of sanitary authorities, this form of trap, formerly used for receiving wastes from baths, sculleries, etc., is prohibited.

Belly (*Leather Manufac.*) The thin under part of tanned hide: used for slippers, thin straps, and uppers of boots.

—— (*Typog.*) The front or nicked side of a type.

Belt (*Cost.*) A band or cincture used to keep flowing costumes in place, or as a support for a sword, dagger, etc. Generally made of leather, and often richly adorned.

Belt *or* **Strap** (*Eng.*) A strap used for transmitting power by pulleys with a smooth surface: made of leather, cotton, catgut, rubber, etc.

Belt Coupling (*Eng.*) The method of joining the ends of a belt, commonly by lacing or riveting: in catgut belts by a hook and eye screwed on to the ends.

Belt Dressing (*Eng.*) Materials, such as oils, tallow, resin, applied to belts to preserve them.

Belt Fork, Strap Fork (*Eng.*) A device for sliding a belt from one pulley to another alongside it; it has two parallel rods, between which the belt can run freely without contact until the fork is moved along parallel to the shaft, when the belt is displaced by the fork, and is transferred from one pulley to the other without the necessity of stopping its motion.

Belton Stone. *See* BUILDING STONES.

Belt Tension (*Eng.*) The pull in a belt expressed in pounds per square inch of cross section; it varies with the nature of the material, but a good rule is to keep it below 300 lb. per square inch in leather belts. Calculated by dividing the transmitted power in foot pounds by the velocity of the rim of the pulley in feet per minute, and by the cross-section of the belt in square inches.

Belt Transmission (*Motor Cars*). The use of a belt to transmit the power from the engine to the main shaft; now practically confined to motor cycles, though even in this case it is often replaced by a chain similar to an ordinary cycle chain.

Bembridge Series (*Geol.*) A member of the UPPER EOCENE rocks, especially well developed in the Isle of Wight, where they consist of strata which are chiefly estuarine in origin. Their thickness amounts to about 25 ft. They are sometimes classed as OLIGOCENE (*q.v.*)

Ben (*Music*). Well, as *Ben marcato*, well marked.

Bench (*Carp. and Join.*) A very strong and heavy table, fitted with a screw, or vice, and a stop, for joiners to work at. Also applied to the table at which many trades are carried on. *See* BENCH SCREW.

—— (*Mining*). (1) Divisions in seams of coal, consisting of clay, etc. (2) A projection at the outcrop of a seam.

Benched (*Build.*) When a foundation is built on sloping ground it is formed in steps, called benches.

Bench Hook (*Carp.*) An appliance for holding a long piece of work steady on the bench while cutting the shoulders of tenons, planing up, etc.

Bench Marks (*Surveying*). Marks, the position and level of which are known, made in the course of a survey and used for reference. Those made by the Ordnance Survey of Great Britain take the form of a broad arrow, usually chiselled on some permanent stone slab.

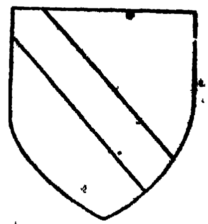
Bench Planes (*Carp.*) Jack, trying, and smoothing planes.

Bench Screw (*Carp.*) A vice at the end of a bench to hold the material to be worked.

Bench Tools *and* **Machines.** Tools and small machines which can be used on the bench (*e.g.* a bench drilling machine), so called in distinction to larger tools and machines which require an independent place in the workshop.

Bench Work (*Carp. and Eng.*) Processes carried out with the smaller tools (and machines) on the bench, as distinguished from processes carried out with the large machines or in the erecting shop.

Bend (*Her.*) An ordinary which crosses the shield from dexter chief to sinister base. If a charge is on it, it occupies one-third of the shield; if uncharged, only one-fifth.



BEND (*Her.*)

—— (*Leather Manufac.*) A butt (*q.v.*) split longitudinally down the middle produces a pair of bends. Bends are bought chiefly by large boot manufacturers for soles.

—— (*Plumb.*) Any curved pipe.

Bending *or* **Flexure.** The amount of curve (or curvature) produced in a beam by the load; its exact measure is given by taking the reciprocal of the "radius of curvature"—*i.e.* the radius of the circle whose curvature most nearly coincides with the curve of the beam. In most cases the curvature of a beam varies, being least at the supports and greatest midway between them.

Bending Cycle Tubes. Tubes are filled with sand, resin, or a soft alloy, and bent over a "former" of the requisite shape. Tubes are bent either hot or cold; if the latter, they must be in a soft (annealed) state first. The process of bending in the cold hardens the tube again, and it is usually left in this condition.

Bending Moment. The bending moment at any point in a beam is the sum of the moments of all the forces acting on the beam on either the right or left side of the cross section through the point—*i.e.* the product of each force into its distance from the point is found, and the sum of all such products on either side of the point gives the total bending moment at the point.

Bending of Strata (*Geol.*) Experiments have been made by Miall upon thin slabs of limestone with a view to finding whether these could be bent by artificial means in such a manner as to retain the flexure and yet not fracture. Pressure applied rapidly caused the slabs to break; but when applied very gradually the resulting flexure proved to be permanent. Amongst highly disturbed rocks some very striking examples of crumpled strata are to be found.

Bendlet (*Her.*) Diminutive of bend; also called a garter; it is one-half of a bend (*q.v.*)

Bendy (*Her.*) Divided into an equal number of bends.

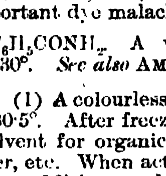
Bengal Lights. Are of various composition—*e.g.* for a white light, shellac, 1 part; barium nitrate, 6 parts; magnesium powder, 2·5 parts: for a red light, 5 parts of strontium nitrate replace the barium nitrate.

Benzalchloride, $C_6H_5CHCl_2$. A liquid boiling at 213° yields benzaldehyde when heated with water, or, better still, milk of lime under pressure. Made by passing chlorine into boiling toluene until the theoretical gain in weight is obtained.

Benzaldehyde, C_6H_5CHO. Oil of bitter almonds. A liquid, smelling like almonds: boils at 179°. It is prepared from bitter almonds, which contain amygdalin (*q.v.*) The amygdalin, acted on by emulsin or hydrochloric acid, yields the oil of bitter almonds. Can be obtained artificially by treating benzylchloride, $C_6H_5CH_2Cl$, with a solution of lead nitrate, or from benzalchloride (*q.v.*) It is easily oxidised to benzoic acid, C_6H_5COOH. Much used in flavouring sweets, etc., and in the manufacture of the important dye malachite green.

Benzamide, $C_6H_5CONH_2$. A white crystalline solid melting at 130°. *See also* AMIDES.

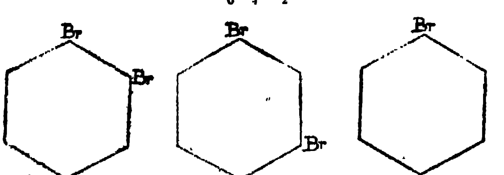
Benzene, C_6H_6. (1) A colourless peculiar-smelling liquid boiling at 80·5°. After freezing, it melts at 6°. It is a valuable solvent for organic substances, such as fats, indiarubber, etc. When acted on by chlorine in sunlight it forms addition products—*e.g.* benzene hexachloride, $C_6H_6Cl_6$. Chlorine in presence of iodine (halogen carrier) gives substitution products—*e.g.* monochlorbenzene. Bromine behaves in the same way. Nitric acid yields according to conditions of action nitrobenzene (*q.v.*) or metadinitrobenzene (*q.v.*) Boiled with sulphuric acid, it gives benzene sulphonic acid; when one monovalent atom such as bromine or one monovalent group such as the nitro group (NO_2) replaces one of the six hydrogen atoms in benzene, only one compound is obtained, no matter which hydrogen atom is replaced. When two such atoms or groups replace two hydrogen atoms, three and only three compounds can be obtained; when three such atoms or groups replace three hydrogen atoms, three compounds are again obtained. The only formula for benzene which accounts for these facts is the following:



BENZENE.

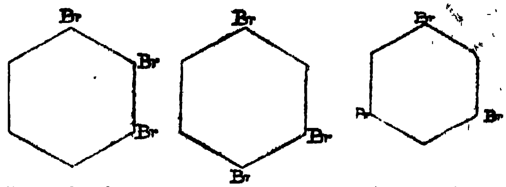
in which the carbon atoms are joined in a ring and one H atom is attached to each. (The ring is represented by the regular hexagon.) So we have

$C_6H_4Br_2$



Ortho-dibrombenzene or 1:2-dibrombenzene. Meta dibrombenzene or 1:3-dibrombenzene. Para-dibrombenzene or 1:4-dibrombenzene.

$C_6H_3Br_3$



Vicinal tribrombenzene or 1:2:3 tribrombenzene. Unsymmetrical tribrombenzene or 1:3:4 tribrombenzene. Symmetrical tribrombenzene or 1:3:5 tribrombenzene.

The carbon atoms are numbered as shown in the figure; also the C and H atoms are often omitted for convenience. Each C atom is represented as trivalent; the exact mode of disposal of the fourth combining unit is unknown. Benzene is obtained by heating benzoic acid with soda lime. On the large scale it is obtained from coal tar (*see* COAL GAS MANUFAC.) The part which distils up to 170° is redistilled, and the part up to 110° shaken with sulphuric acid, then caustic soda, and again distilled. The part that distils at 80° to 82° is fairly pure benzene. Benzene is also obtained synthetically by heating acetylene gas.

Benzene Sulphonic Acid, $C_6H_5SO_2OH$. When benzene is boiled with sulphuric acid for some hours, combination occurs, and this substance is formed. Colourless plates melting at 50° readily soluble in water and alcohol. Fused with caustic soda, it gives phenol, used in the manufacture of ether.

Benzidine, $H_2N \,.\, C_6H_4 \,.\, C_6H_4 \,.\, NH_2$. *Paradiamidodiphenyl.* White plates melting at 122°. Formed by reduction of azobenzene with tin and hydrochloric acid:

$$C_6H_5N = N \,.\, C_6H_5 \rightarrow \underset{\text{H}}{C_6H_5NH} \,.\, \underset{\text{Hydrazobenzene.}}{NH \;\; C_6H_5} \rightarrow$$

$$H_2NC_6H_4 \,.\, C_6H_4NH_2.$$

Parent substance of a number of dyes capable of dyeing cotton without a mordant—*e.g.* Congo red. *See also* DYES AND DYEING.

Benzine. A popular term, not used in exact nomenclature. Sometimes applied to commercial benzene, sometimes to petroleum, which is quite a different substance chemically.

Benzoic Acid, C_6H_5COOH. A shining white crystalline solid of characteristic smell; melts at 120°; soluble, 1 in 400 parts water at 15°; readily in hot water, also in alcohol and ether. It is a powerful antiseptic. When taken internally, it appears in the urine as hippuric acid (*q.v.*) Obtained by sublimation from gum benzoin, which contains 12 to 20 per cent. of the acid; also as a byeproduct in the manufacture of benzaldehyde. When heated with lime (CaO), it gives benzene (C_6H_6). With bromine, nitric or sulphuric acid it forms metasubstitution products.

Benzoin (*Botany*). *Styrax benzoin* (order, *Styracaceæ*). A fragrant resin obtained by incision of the bark. It is used in medicine, in perfumery, and in making incense.

Benzol. Another name for Benzene.

Benzonitrile. *See* NITRILES.

Benzophenone, $C_6H_5COC_6H_5$ (*Diphenylketone*). Crystalline solid existing in two forms—an unstable

form melting at 26°, and formed by boiling the stable form, which melts at 46°: the former reverts to the latter on standing. Pleasant smell. Obtained from benzene, and either benzoylchloride or carbonylchloride, in presence of aluminium chloride; also by distilling calcium benzoate. Distilled with zinc dust yields diphenylmethane. *See also* KETONES.

Benzopurpurines. May be regarded as benzidine derivatives; they are dyes which dye unmordanted cotton red. Benzopurpurine B is

$$\begin{array}{l} C_6H_3\left\langle\begin{array}{l}N = N - C_{10}H_5\left\langle\begin{array}{l}NH_2\\SO_3Na\end{array}\right.\\CH_3\end{array}\right.\\ \quad | \\ C_6H_3\left\langle\begin{array}{l}CH_3\\N = N - C_{10}H_5\left\langle\begin{array}{l}SO_3Na\\NH_2\end{array}\right.\end{array}\right.\end{array}$$

This is the salt known as Congo red. *See also* DYES AND DYEING.

Benzoquinone. *See* QUINONE.

Benzoyl. The name given to the group C_6H_5CO-. It does not exist uncombined. BENZOYLCHLORIDE, $C_6H_4 . CO . Cl$, is an important reagent in organic chemistry; it is a colourless fuming liquid boiling at 200°. Obtained by action of phosphorus pentachloride on benzoic acid. Decomposed by water into hydrochloric and benzoic acids. *See also* BAUMANN-SCHOTTEN REACTION.

Berberine, $C_{20}H_{17}NO_4$. An alkaloid found in a number of plants—*e.g. Berberis vulgaris*, yellow-brown needles melting at 145°. Optically inactive; soluble in water and in alcohol. Forms gold-coloured salts. Alkalis colour its solution red, and chlorine water colours its hydrochloride blood red. It is not official. It is probably a quaternary ammonium base (*q.v.*) Among its oxidation products may be mentioned $\alpha\,\beta'\,\gamma$, pyridine tricarboxylic acid, hemipixic acid (1 : 2 methoxybenzene, 3 : 4 dicarboxylic acid), and hydrastic acid, the latter showing that berberine is related to hydrastine.

Bergamot (*Botany*). *Citrus aurantium* (var., *Bergamia*; order, *Rutaceæ*). A fragrant essence extracted from the rind of the fruit of a variety of the orange. *See* CITRUS.

Berkefeld Filter (*Hygiene*). This is a valuable form of domestic filter; it consists of a cylinder of diatomaceous earth called Kieselguhr, which is enclosed in an outer case. The water enters at the top under pressure, and is forced inwards through the earth. It frees the water from organisms.

Berlin Blue. Another name for Prussian blue (*q.v.*)

Berthelot's Calorimeter (*Heat*). An apparatus for determining the latent heat of evaporation of liquids by condensing the vapour in a helical tube immersed in a vessel of water whose rise of temperature can be noted.

Beryl (*Min.*) A silicate of aluminium and beryllium, $3BeSiO_3 . Al_2Si_3O_9$: silica = 66·8, aluminium = 19·1, berylla = 14·1 per cent. Hexagonal. Colour, emerald green to dirty brown or grey. One opaque crystal from Massachusetts was said to weigh 2½ tons. The bright green variety is EMERALD (*q.v.*), the blue green is AQUAMARINE (*q.v.*); both valuable as gems. Brazil, Siberia, and Saxony are important localities. *See also* PRECIOUS STONES.

Beryllium, Be. Atomic weight, 9. Called also GLUCINUM, from the fact that some of its salts—*e.g.* the sulphate—are sweet tasted. It is a white metal, obtained by heating the chloride $BeCl_2$ with sodium. It belongs to the same chemical family as magnesium. It is found in the BERYL (hence its name) and in emerald.

Bessemer Converter (*Met.*) The pear-shaped vessel used in converting cast iron to steel in the Bessemer process (*q.v.*)

Bessemer Pig (*Met.*) Cast (or pig) iron specially suited to the Bessemer process. For the acid process an ore with a relatively high amount of silica (SiO_2), not less than 2 per cent., and a low percentage of sulphur and phosphorus, was preferred; for the basic process the reverse is the case, the phosphorus giving a valuable slag.

Bessemer Process (*Met.*) The conversion of cast iron to steel by oxidising the carbon by means of a current of air blown through the iron while molten; the air oxidises the carbon to carbonic oxide (CO_2) and carbon monoxide (CO), and at the same time maintains the iron at a suitably high temperature by this oxidation, until practically the whole of the carbon is removed. *See also* IRON *and* STEEL.

Best *and* **Best Best,** *or* **B.** *and* **B.B.** Grades of cast iron. *See* IRON.

Bestiarium (*Archæol.*) A name given to early books on natural history. They were often in verse, and moralised on the peculiarities of animals.

Betaine, $\begin{array}{l}CH_2 - N(CH_3)_3\\ \ | \qquad\quad |\\ CO \ - \ O\end{array}$ (*Oxyneurine, Lycine, Trimethylglycocoll*). Hygroscopic crystals; forms well crystallised salts. Occurs in the sugar beet, in cotton seed, and in wheat sprouts. Has been found with ptomaines in some poisonous edible mussels. Obtained by careful oxidation of choline (*q.v.*); also when trimethylamine is heated with monochloracetic acid. It is not poisonous.

Beton (*Build.*) *See* CONCRETE.

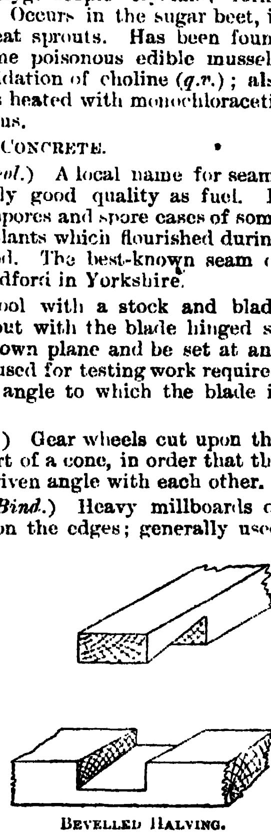
Better Bed Coal (*Geol.*) A local name for seams of coal of exceptionally good quality as fuel. It consists largely of the spores and spore cases of some of the lycopodiaceous plants which flourished during the Carboniferous Period. The best-known seam of the name occurs at Bradford in Yorkshire.

Bevel (*Tools*). A tool with a stock and blade resembling a square, but with the blade hinged so it can be moved in its own plane and be set at any angle with the stock; used for testing work required to be cut to any given angle to which the blade is previously adjusted.

Bevel Gearing (*Eng.*) Gear wheels cut upon the surface of a cone or part of a cone, in order that the shafts may run at any given angle with each other.

Bevelled Boards (*Bind.*) Heavy millboards of good quality, bevelled on the edges; generally used for antique work.

Bevelled Halving (*Carp.*) HALVING (*q.v.*) in which the internal cut surfaces which are in contact are inclined at a small angle to the plane of the two pieces of timber; it is only used when there is a heavy pressure on the wood which keeps the joint in place.



BEVELLED HALVING.

Bevelling (*Carp, etc.*) To form an acute or obtuse angled surface.

Bezant (*Archæol.*) A gold coin of Byzantium, an ancient city of Thrace, situate on the Bosphorus. When the seat of the Roman government was fixed there by Constantine the Great in 330 A.D., the name was changed to Constantinople. Bezants were current in England from the tenth century to the reign of Edward III.

Bezants (*Her.*) Flat gold roundles or circles, without impress. Originally gold coins struck at Byzantium.

Bezants Tourteaux (*Her.*) Roundles in which the dexter side is half a bezant (*or*) and the sinister half a tourteau (*gules*).

Bezanty **Bezantée** (*Her.*) Charged with bezants.

Bezel. (1) The edge and oblique faces of a cut gem. (2) The grooved ring for holding the glass of a watch or clock. (3) The sloping edge of a cutting tool.

Biacca (*Paint.*) White lead.

Biadetto (*Paint.*) A blue paint made from copper.

Bianco Secco (*Paint.*) A wash or paint made from lime, used in fresco work.

Biaxial Crystal (*Physics*). One with two OPTICAL AXES (*q.v.*)

Bibcock (*Eng.*) A tap or cock of the ordinary shape in which the nozzle is bent downward.

Bibelots (*Art*). Objects of art, or curiosities, used for decorative purposes.

Bicarbonates. Compounds formed by replacement of half the replaceable hydrogen of carbonic acid by metals. Carbonic acid has the formula H_2CO_3; sodium bicarbonate is $NaHCO_3$; potassium bicarbonate is $KHCO_3$; and calcium bicarbonate is $Ca(HCO_3)_2$.

Bice (*Paint.*) A blue paint, inferior to ultramarine.

Bichromates (*properly called* **Dichromates**). Salts of the unknown acid $H_2Cr_2O_7$; *e.g.* $K_2Cr_2O_7$ is potassium dichromate, often called bichromate of potash.

Bickern. A BEAK IRON (*q.v.*)

Biclinium (*Archæol.*) A couch or settee for two persons.

Bicorporate (*Her.*) Having two bodies joined to one head.

Bicycle. A bicycle may be defined as a vehicle propelled by foot power by the rider, and having two wheels in line with each other. *See also* CYCLES.

Biennial (*Botany*). A herbaceous plant which persists for two seasons. In the second year the plant flowers and fruits.

Bifilar Suspension (*Phys., Mechanics*). Two similar fibres of equal length, and usually parallel, are often used to suspend an object, such as an electrometer needle. At rest, the two fibres lie wholly in the same plane; if the suspended object be turned, it is slightly raised at the same time, and gravity tends to restore it to its original position. Thus a continual directive force is obtained which is independent of any torsion in the fibres themselves, or of magnetic or other external forces.

Bifrons (*Sculp.*) Two faces put back to back so as to form one head—*e.g.* Janus is often so represented.

Biga (*Archæol.*) A Roman chariot drawn by a pair of horses.

Bight. A loop in a chain or rope; also a general term for a bend.

Bile (*Zoology*). A secretion of the liver stored up in the gall bladder. It is passed out into the duodenum (*q.v.*) by means of the bile duct. Bile is alkaline, counteracting the acidity of the chyme. It also acts upon fats to form an emulsion.

Bilge Water (*Eng.*) The water which accumulates in the bottom of a ship's hold; it is removed by bilge pumps, worked by hand or steam, or occasionally in old ships by a small windmill on deck.

Bill (*Arms*) A cutting weapon with a curved point like a beak of a bird, used in warfare in the fourteenth and fifteenth centuries.

BILL, 15TH CENTURY.

—— (*Typog.*) A list or scale of the quantity of each letter required for a fount of type.

Billeté (*Her.*) Strewn with billets.

Billet Moulding (*Architect.*) An enriched moulding used in Norman strings and archivolts. It consists of a series of small pieces or billets, either circular or square in cross section, placed in a hollow moulding, the spaces between the billets being usually the same length as the billets.

Billets (*Her.*) A charge like a small oblong, sometimes shown voided.

Bill Head *or* **Bill Hook.** A cutting instrument curved at the end and broad in the blade.

Bind *or* **Tie** (*Music*). A curved line placed over or under two notes of the same pitch to show that the second is not to be re-struck, but the sound of the first note is to be sustained for the time of the two. Sir W. S. Bennett introduced the sign ⎴ instead.

Binder *or* **Binding Joist** (*Carp.*) The beam supporting the common or bridging joists (*q.v.*)

Binders for Slides (*Photo.*) The strips of black or coloured paper used to fasten round the edge of lantern slides to hold the plate and its cover glass together.

Binding Straps (*Eng., etc.*) The metal holders of the tool in planing and shaping machines.

Binding Wire. Fine wire (iron, brass, or copper) used for holding small joints during brazing, or sometimes permanently.

Bioscope. *See under* CINEMATOGRAPH.

Bioses (*Chem.*) A name given to those sugars which contain twelve atoms of carbon and are resolved on hydrolysis into two sugars, each of which contains six carbon atoms; *e.g.* cane sugar, maltose, and lactose are bioses.

Biotite (*Min.*) One of the mica group. A silicate of magnesium, potassium, iron, and aluminium, the exact composition of which varies considerably. It is a common constituent of eruptive and metamorphic rocks, and is widely distributed. It is monosymmetric, and it usually occurs as pseudo-hexagonal plates with a perfect basal cleavage; the laminæ are transparent and elastic.

Bipennis (*Arms*). A double-edged axe

Birch. *See* WOODS.

Birdbolt (*Her.*) A blunt arrow.

Birdlime. Not a definite chemical substance; it contains about 6 per cent. of caoutchouc, esters of palmitic acid, and other substances of unknown constitution. It is prepared from the inner bark of the holly.

Bird of Paradise (*Zoology*). Family, *Paradiseidæ*; order, *Passeres.* A Polynesian family of birds, of nearly fifty species, much sought after for the sake of their beautiful plumage.

Bird's Beak (*Architect.*) A moulding used in Greek architecture. It consists of an ovolo or an ogee with a hollow moulding under, and with or without a fillet between. It is frequently used in the capital of the Greek Doric anta.

Bird's Eye (*Plumb.*) A hole accidentally made in a pipe by a clumsy workman.

Bird's Eye Maple (*Dec.*) Grainers in imitating this wood prepare a ground of white lead tinted either with a very little vermilion or with Oxford ochre. The graining colour is usually burnt umber ground in water, to which is added a little raw sienna. *See also* WOODS.

Bird's Eye View. A view of a landscape such as would be seen by a bird flying.

Bird's Mouth (*Carp.*) A triangular notch. Rafters are birdsmouthed on to the wall plate.

Biremis (*Archæol.*) An ancient vessel with a double bank of oars on each side.

Biretta, Beretta (*Cost.*) A square-shaped cap worn by persons in orders (R.C.Ch.) The biretta of the priest is black, that of a bishop purple, and that of a cardinal red.

Birkhill Shales *or* **Graptolitic Mudstones** (*Geol.*) A section of the Silurian rocks, of marine origin, well developed in the Lake District, and near Moffat, as well as at other places in the south of Scotland. It consists of a small thickness of black mudstones, which seems to have been formed in deep water, and near the outer verge of the area of terrigenous deposits. It contains an extensive suite of graptolites, many species of which occur only on a definite platform within these rocks, and thus form palæontological zones of much value in stratigraphical geology.

Birth Rate (*Hygiene*). The birth rate of a town is calculated in the following manner: Supposing a town has a population of 170,000, and the number of births during the year is 4,850, then the annual birth rate is

$$\frac{4{,}850 \times 1{,}000}{170{,}000} = 28{\cdot}5.$$

The death and marriage rates are calculated in the same way.

Bis (*Music.*) Twice: shows that the portion so marked is to be performed twice.

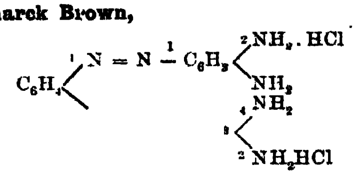
Biscuit (*Pot.*) *See* BISQUE.

Biscuit Oven (*Pot.*) *See* BISQUE OVEN.

Bisellium (*Archæol.*) Literally, a seat or chair for two; allotted to distinguished persons as an honour on public occasions among the Romans.

Bishops' Length (*Paint.*) Canvas, 58 by 94 in.

Bismarck Brown,



A dye obtained from metaphenylene diamine by the diazo reaction (*q.v.*) Its formation is used as a test for the presence of nitrites in water. *See also* DYES AND DYEING.

Bismuth, Bi (*Chem.*) Atomic weight, 208. A brittle crystalline metal, greyish-white colour, with tinge of pink. To obtain it the ore is roasted and then melted with charcoal, iron, and slag obtained in smalt making. It is readily oxidised to the oxide Bi_2O_3; scarcely acted on by hydrochloric acid, but readily by nitric acid forming the nitrate. Hot strong sulphuric acid forms the sulphate $Bi_2(SO_4)_3$. Bismuth is used in making "fusible metals." This element occurs native in foliated or granular masses and also in branching forms running through the matrix. It crystallises in rhombohedral forms, much resembling a cube. Often found in association with ores of silver, cobalt, zinc, and lead. The native metal is the most important source of bismuthe. Obtained from Botallack in Cornwall, Caldbeck Fells in Cumberland, Saxony, Bohemia, Norway, etc.

Bismuth Compounds. BISMUTH OXIDE, Bi_2O_3, a brownish-yellow compound obtained by heating the nitrate; insoluble in water, soluble in acids. BISMUTH CHLORIDE, $BiCl_3$, forms white deliquescent crystals, and is obtained by dissolving the oxide in hydrochloric acid or the metal in *aqua regia*; its solution gives, with much water, a white precipitate of BISMUTH OXYCHLORIDE, BiOCl. BISMUTH NITRATE, $Bi(NO_3)_3$, a white deliquescent crystalline solid formed by dissolving the metal, oxide, or carbonate in nitric acid. With water its solution forms the important BISMUTH OXYNITRATE, $BiONO_3$, a basic nitrate; insoluble in water as such, but decomposed by it on prolonged action. Much used in medicine as an astringent and antiseptic; also used as a cosmetic and in painting on porcelain.

Bismuthine (*Min.*) Bismuth trisulphide, Bi_2S_3; it usually occurs in acicular crystals of the rhombic system. Sometimes massive. Colour, lead grey. From Cornwall, Cumberland, Saxony, etc.

Bismuth Ochre (*Min.*) Native bismuth trioxide, Bi_2O_3; its form is rhombic. It occurs as a greenish-yellow incrustation on other bismuth ores, but is not common.

Bisque (*Pot.*) The term given to pottery or porcelain after firing in the bisque oven and before being glazed.

Bisque Oven, Biscuit Oven (*Pot.*) Is that in which the clay articles are placed, and the heat of which renders them more or less vitrified.

Bistre (*Paint.*) A brown pigment prepared from soot.

Bisulphates (*Chem.*) Salts of sulphuric acid (H_2SO_4) in which half the hydrogen of the acid is unreplaced by metals; *eg.* $KHSO_4$ is potassium bisulphate.

Bisulphites (*Chem.*) Salts of sulphurous acid (H_2SO_3) in which half of the hydrogen of the acid is unreplaced by metals; *e.g.* $NaHSO_3$ is sodium bisulphite.

Bit (*Carp.*, *Eng.*) Name applied to several tools or parts of tools—*e.g.* the copper tool used in soldering (*see also* SOLDERING IRON), and the cutting tool used with a brace or drill. *See* TWIST BIT, CENTRE BIT, *etc.*

Bite (*Typog.*) A blank left in a printed page owing to the frisket accidentally covering a portion of the forme.

Biting In (*Engrav.*) The action of the acid on metal in etching. *See* ENGRAVING AND ETCHING.

Bittern (*Chem.*) The mother liquor remaining after common salt has been separated by crystallisation from sea water. It was in this liquor that Balard discovered bromine in 1826.

Bitter Spar (*Min.*) A ferruginous variety of DOLOMITE (*q.v.*)

Bitumen (*Paint.*) A pigment made from asphalt, of a colour resembling sepia. Being susceptible to the weather, it should be used very sparingly, or perhaps it would be better not at all. Cf. many of the pictures of Sir Joshua Reynolds.

Bitumens (*Min.*) A series of carbon compounds of the olefiant and paraffin groups. They usually occur as mixtures. Most are semi-solid or liquid, and many have aromatic odours. The principal members are: Hachettite (carbon = 85·5, hydrogen = 14·5 per cent.); Ozocerite (carbon = 84·5, hydrogen = 13·7 per cent.); Amber (carbon = 79·0, hydrogen = 10·5, oxygen = 10·5 per cent.); Petroleum (a mixture of the series C_nH_{2n+2}), Asphalt, Naphtha, etc.

Bituminous Coal. Coal containing a large amount of tarry matter or bitumen. *See also* COAL.

Bituminous Paint (*Eng.*) A paint or varnish composed of tar mixed with resin and tallow; used for ironwork under water.

Biuret (*Chem.*) A compound formed by carefully heating urea at 150° to 160°. Needles, soluble in water and alcohol; melts at 190°.

$$\underset{\text{Urea.}}{2CO\begin{matrix}\diagup NH_2\\ \diagdown NH_2\end{matrix}} = \underset{\text{Biuret.}}{\begin{matrix}CO\diagup NH_2\\ \quad\ \ \diagdown NH\\ CO\diagup \\ \quad\ \ \diagdown NH_2\end{matrix}} + NH_3$$

Caustic soda and copper sulphate solutions added to its solution in water give a violet red colouration. On heating, biuret yields ammonia and cyanuric acid (*q.v.*)

Biuret Reaction. When caustic soda and copper sulphate solutions are added to an aqueous solution of an albumin a violet red colour is produced, while albumoses and peptones give a pure red colour. The coloured compound has the formula:

$$NH\left\langle\begin{array}{c}CO - NH_2 - Cu - H_2N - CO\\ \quad\ \ | \qquad\qquad\quad\ \ |\\ \quad OH \qquad\qquad\ HO\\ \quad OH \qquad\qquad\ HO\\ \quad\ \ | \qquad\qquad\quad\ \ |\\ CO - NH_2 - KK - H_2N - CO\end{array}\right\rangle NH.$$

The biuret reaction is given by all substances which contain $2(-CONH_2)$ or $2(-CSNH_2)$: groups united either (1) to each other, (2) to the same carbon atom, (3) to the same nitrogen atoms. It will detect one part of a peptone in 100,000 of water; less sensitive for other substances.

Black (*Eng.*) Applied to work left rough just as it came from the forge or foundry, as well as to work which has been treated with a varnish, paint, or other coating.

Black (*Paint.*) The so-called colour is due to the circumstance that the substances composing it absorb all the rays of light and reflect none. Black pigments are either made by incompletely burning various organic substances or are found in a mineral state. Among the former are carbon black, bone black, lamp black, ivory black, Spanish black, and vegetable black; among the latter, graphite, Frankfort black, etc. *See also* BRUNSWICK BLACK, DROP BLACK, *and* GAS BLACK.

——, **Aniline.** *See* DYES AND DYEING.

Black Ash. *See* ALKALI.

Black Band Ore (*Min.*, *Met.*) Clay iron ore (*q.v.*) mixed with bituminous matter. Occurs chiefly in shales of Carboniferous age in various parts of Britain, in Germany, and some other places.

Black Chalk. A mineral substance used for making crayons.

Black Copper (*Met.*) The product of one of the stages of smelting copper.

Black Damp (*Mining*). Carbonic acid gas.

Black Diamond *or* **Carbonado** (*Min.*) Synonyms for BORT (*q.v.*)

Blackdown Beds (*Geol.*) A subdivision of the CRETACEOUS ROCKS which has yielded an abundant marine fauna. Its precise geological position has formed the subject of much discussion.

Black Flux. A mixture of potassium carbonate and charcoal obtained by heating cream of tartar out of contact with air. For some purposes this mixture contains too much carbon; in this case the cream of tartar is heated with more or less nitre. *See* FLUX *and* REDUCING MIXTURES.

Blacking *or* **Blackening** (*Moulding*). Carbonaceous dust (graphite, ground charcoal, etc.), which is dusted over the surface of a mould to prevent sudden contact of the fluid metal and the sand of which the mould is formed.

Blacking Mill (*Moulding*). The grinding machine for preparing the fine powder used for blacking a mould.

Black Jack (*Archæol.*) A capacious can, formerly made of waxed leather, but now made of metal.

—— (*Min.*) A synonym for ZINC BLENDE (*q.v.*), used by miners.

Black Japan (*Dec.*) A black quick drying varnish much used by carriage painters, but useful also to house painters in preparing rich dark colours for glazing and scumbling (*q.v.*) The absence of a greenish or a reddish cast is the chief characteristic of good quality.

Blacklead (*Eng.*, *etc.*) Graphite (or plumbago), one of the natural forms in which carbon occurs. Used as a lubricant where oil is undesirable—*e.g.* on cycle chains, on wooden surfaces where friction occurs, and on the surfaces of patterns to facilitate withdrawal from the mould; also used in the foundry as BLACKING (*q.v.*) *See also* PLUMBAGO.

Black Letter (*Typog.*) A name applied to the form of type used by the early printers, which was subsequently displaced by "Roman" type. Also called "Gothic" or "Old English." The following are black letter type of the sixteenth century: 𝔄 𝔅 ℭ.

Black Oils. Mineral oils which have not been chemically purified. Used for lubrication if sufficiently viscous. *See* PARAFFIN *and* FULLER'S GREASE.

Black Sand (*Moulding*). Old foundry sand, forming the floor of the foundry, and used for the main part of a mould, but not in immediate contact with the pattern.

Black Smoke (*Eng., etc.*) The result of incomplete combustion caused by faulty grates or careless stoking. The discharge of black smoke is forbidden by law, and, moreover, represents an enormous loss of fuel, since the furnace gases are carrying off great quantities of carbon in a very finely divided form.

Black Tellurium (*Min.*) A synonym for NAGYAGITE (*q.v.*)

Blackwood. *See* WOODS.

Blade. The cutting portion of various tools, or the thin, flat part of a square, bevel, etc.

Bladed (*Her.*) When the stalk of corn is of a different tincture from the ear.

Blanc Fixe (*Dec., etc.*) An artificial sulphate of barium, very white and fine and somewhat heavy. Principally used in papermaking and in the manufacture of wallpaper colours. It also enters largely into the composition of lithopone (*q.v.*), Orr's white, etc.

Blank (*Coins*). The disk stamped out of a sheet of metal ready for striking.

—— (*Eng.*) A piece of metal roughly cut, cast, or forged to a particular shape ready for accurate working up by hand or machine.

Blank End (*Eng., etc.*) The closed end of a pipe or channel.

Blanket (*Woollen Manufac.*) A thick, heavy fabric, usually plain woven and covered with fibres on both sides. WOOLLEN BLANKETS are made of wool; UNION BLANKETS of a cotton warp and wool weft. COTTON BLANKETS are made entirely of cotton with a soft spun weft.

—— (*Engrav.*) A piece of woollen material wrapped round the roller of a press to equalise the pressure.

Blank Hole (*Eng.*) A misplaced rivet or bolt hole which comes opposite to solid material instead of a corresponding hole.

Blank Wall (*Build.*) A wall without an opening in it.

Blank Window (*Build.*) A window opening filled up with brickwork in the form of a panel.

Blast (*Met.*) Air forced into a furnace by a fan or blower. Used in nearly all metallurgical operations, and in steam boilers when required to work at their maximum capacity. *See* FORCED DRAUGHT.

Blasted (*Her.*) A branch with all its leaves torn off; also termed "starved."

Blast Furnace (*Met.*) A vertical furnace with a constriction or narrowing at the top and bottom; made of iron or brick, lined with some very refractory firebrick or other material. For producing pig iron from the ore, which is shot in from the top along with fuel and some flux, and kept at an intense heat by a hot or (less frequently) cold blast. Once lit, the furnace may run for several years before being "blown out" or stopped. The fluid iron is drawn off at intervals from the lower part, the slag (which collects above the iron) being drawn off continuously through a special opening. *See also* FURNACES.

Blasting Gelatine. An explosive mixture of nitroglycerine and nitrocellulose, less highly nitrated than gun cotton.

Blast Main (*Eng.*) The large pipe carrying the air from the fan or blower to the furnace.

Blast Pipe (*Met.*) The pipe discharging the exhaust steam of a locomotive into the chimney, thus producing a forced draught through the fire.

Blazed Pig *or* **Glazed Pig** (*Met.*) Inferior pig iron containing a high percentage of silica. It is often produced soon after a furnace is started.

Blazing Off (*Eng.*) Tempering steel by coating it, after hardening, with grease or oil, and heating till the vapour from the oil "flashes" or lights.

Blazon (*Her.*) (1) A shield or coat of arms; the charges or devices are called "blazons." (2) A description of armorial bearings in proper heraldic terms.

Blazonry (*Her.*) The art of delineating or describing coats of arms in proper heraldic terms.

Bleached Cotton Cloths (*Cotton Weaving*). A variety of makes may be included under this heading. All of them are woven and purely sized in the grey state, and bleached afterwards. The following are a few: Longcloths, cambrics, jacconettes, lawns, nainsooks, toilets, lenos, etc.

Bleaching. The removal of colouring matter from a fabric by a process of oxidation or reduction. OXIDATION is effected by soaking the fabric in a solution of bleaching powder (*q.v.*), then in a dilute acid, such as sulphuric acid; in this way hypochlorous acid (*q.v.*) is liberated, and this oxidises the colouring matter to a colourless compound. REDUCTION is effected by submitting the fabric to the action of sulphurous acid (*q.v.*); this is often done by suspending the fabric in a closed room, on the floor of which sulphur is burnt. In this case hydrogen is added to the colouring matter, and a colourless product is formed. Fabrics bleached in this way are liable to regain their colour on exposure to air and light. Cotton and linen are bleached by the first method, and wool, silk, and straw by the second. In all cases the fabric should be chemically cleaned before being subjected to the bleaching process. Hydrogen peroxide, obtained by the action of hydrochloric acid on sodium peroxide (*q.v.*), is now sometimes used as a bleaching agent: it bleaches by oxidation.

—— (*Paper Manufac.*) The process of making disintegrated rags or other pulp perfectly white by means of chloride of lime.

Bleaching Powder. A white powder of the composition $Ca\left\langle\begin{matrix}Cl\\OCl\end{matrix}\right.$. It is prepared by passing chlorine over good slaked lime ($Ca(OH)_2$). The operation is carried out in stone chambers, and lasts some days. Heat is evolved during the absorption of the chlorine. Bleaching powder changes on exposure to air and moisture; it contains unchanged slaked lime. When treated with water, the solution contains calcium chloride and hypochlorite: $2Ca.OCl.Cl = CaCl_2 + Ca(OCl)_2$. Acids decompose it, giving chlorine or hypochlorous acid; *e.g.* with hydrochloric acid we may suppose hypochlorous acid is liberated first, and immediately decomposed by hydrochloric acid, giving chlorine:

$$Ca(OCl)_2 + 2HCl = CaCl_2 + 2HOCl$$
$$2HOCl + 2HCl = 2H_2O + 2Cl_2.$$

Its solution, warmed with a solution of a cobalt salt, gives a steady current of oxygen.

Bleak (*Zool.*) *Alburnus lucidus* (family, *Cyprinidæ*). A small fish of the carp tribe found in Europe and Western Asia. Its scales are used in making artificial pearls.

Bled (*Bind.*) When the edge of a book has been cut down to such an extent that the print is affected, it is said to have been "bled."

Bleed (*Plumb.*) To bleed a pipe is to make a small hole to run off the water so that the pipe can be repaired.

Blend (*Paint.*) To gradually pass from one colour to another without abrupt transition.

—— (*Woollen Manufac.*) A mixture of fibres ready for carding.

Blende (*Min.*) Zinc sulphide, ZnS (zinc = 66, sulphur = 34 per cent.); usually a little cadmium is present. Also called SPHALERITE, and by the miners Black Jack. It occurs in complex forms of the cubic system. At one time it was rejected as a useless gangue metal, but now it is a valuable source of zinc and cadmium. Colour usually black. Often associated with lead, copper, and silver ores, and barytes. From Alston Moor, Saxony, Spain, Sweden, Belgium, etc.

Blending (*Woollen Manufac.*) The operation of mixing wool, cotton, mungo, etc. Blending has three distinct applications: (1) To the mixture of two or more qualities of material; (2) to the mixture of two or more colours of material; (3) to the mixture of several qualities and colours of material.

Blind Drift (*Mining*). A passage not leading to any other working; a "cul de sac."

Blind Lode *or* **Vein** (*Mining*). A vein with no outcrop (*q.v.*)

Blind P. (*Typog.*) A paragraph mark, ¶, so named because the loop of the *P* is closed.

Blind Tooling (*Bind.*) Ornamental impressions on the cover of a book produced by heated blocks or tools, not finished with gilt. Called also ANTIQUE.

Blister (*Paint.*) A swelling of the paint on the surface of a picture.

Blister Copper (*Met.*) "Fine metal" (*q.v.*) which has been roasted to expel sulphur and then melted and run into moulds. The gases escaping from the molten copper produce a blistered appearance. *See also* COPPER.

Blistering (*Dec.*) A frequent and serious fault of painted work. Arises from a variety of causes, the most common of which are (1) painting upon a damp surface, (2) imperfect adhesion between coats of paint, (3) improper treatment of knots, (4) the use of too much oil. Painted work in some positions is very liable to become blistered, especially where it receives the full force of the sun. Executing the work in sharp, flat colour (*q.v.*), and afterwards varnishing, generally prevents blistering. A good washable water paint may also be used with success, with a varnished finish. It is important that in every case ample time be given for each coat to dry.

Blisters (*Photo.*) Occur in a film through careless handling or uneven drying in manufacture. They may sometimes be checked by flooding the plate with methylated spirit.

Blister Steel (*Met.*) Steel produced by the cementation process (*q.v.*) The appearance is due to the escape of carbonic oxide gas. *See also* IRON *and* STEEL.

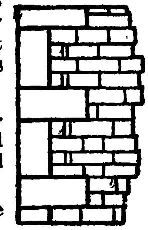
Block (*Eng., etc.*) The wood or metal frame or case carrying the pulleys in lifting tackle.

—— (*Sculp.*) A solid piece of stone or wood unworked.

—— (*Engrav.*) A piece of hard wood on which an engraving is cut.

—— (*Typog.*) A term embracing woodcuts, zincos, electros, etc.

Block and Start (*Build.*) Stones next to an opening, when alternately long and short, form block and start work, as in the figure. *See* QUOINS *and* LONG AND SHORT WORK.



BLOCK AND START.

Block Chain (*Cycles*). *See* CYCLES.

Block Coal. Coal with well marked horizontal and vertical divisional planes.

Block in Course (*Build.*) Stone walling, used chiefly for embankments, etc.; similar to ashlar work (*q.v.*)

Blocking *or* **Backing** (*Carp.*) Pieces of wood let in or fixed to the walls of buildings. To these the joiner's work is secured.

Blocking Course (*Architect.*) A plain course of stone in a classical building placed at the top of a wall immediately above the cornice.

Blocking Out (*Photo.*) Covering parts of the negative with an opaque paint or varnish in order that they may appear white in the print.

Blocking Press (*Bind.*) A machine used for impressing ornamental designs on cloth covers.

Block Joint (*Plumb.*) A wiped joint (*q.v.*) with a flange, used for large lead pipes when in a vertical position.

Block Setting Crane (*Eng.*) A powerful travelling crane (*see* CRANES) used in setting heavy masonry, such as harbour work or bridge piers.

Block System (*Railway Eng.*) The system of signalling used on English passenger railways. The line is divided up into sections, each beginning and ending with a semaphore signal. A train may not enter any section while another train or any part of a train is on it. When no train is on a section, it is said to be "clear"; the signal at the beginning of the section may then be put down or "set at clear" as soon as a train approaches, and the driver can enter the section at once. It is obvious that as long as the Block System is working correctly there is no risk of collision between two trains running in the same direction on the same line of metals; but it does not secure absolute immunity from accidents. Indeed, probably no system of signalling can achieve such a result. For example, if an "up" train became derailed or wrecked, it might obstruct the "down" line, and the signalman would have no indication that the down line was not clear; and if he admitted a train to it, as he would be justified in doing from the information at his command, an accident to the down train would occur.

Block Tin. Tin of second quality, usually cast in ingot or block weighing about 3 cwt. The best quality is known as Refined Tin. *See also* TIN.

Blood (*Zool.*) It consists of a clear fluid (plasma) containing red and white corpuscles. The former are round discs of a yellowish tint, and serve to carry oxygen in combination with their pigment (hæmoglobin); the white corpuscles are amœboid,

colourless, and few in number. Blood is used in various manufactures—*e.g.* in calico printing, in the manufacture of prussiate of potash, and in sugar refining. *See* HÆMOGLOBIN *and* WASTE PRODUCTS: ANIMAL REFUSE.

Bloodstone (*Min.*) A variety of CHALCEDONY of dark green colour, speckled with red; it is also called HELIOTROPE. Much used for seals and rings. *See* PRECIOUS STONES.

Bloom (*Leather Manufac.*) Bloom is ellagic acid, a greyish powder which deposits on the leather in the tan pits. It is practically insoluble in water, and separates out in the tan liquors. *See* BLOOMED BUTT.

—— (*Met.*) The mass of iron taken from the puddling furnace (*q.v.*) after squeezing to expel cinders; also any piece of iron prepared for the hammer or rolling mills.

Bloomary *or* **Bloomery** (*Met.*) The first forge through which iron passes after it has been melted from the ore, and in which it is made into blooms.

Bloomed Butt (*Leather Manufac.*) A butt (*q.v.*) finished with the bloom left in. Chiefly manufactured from South American hides. Originated in and is still chiefly confined to West of England.

Blooming (*Dec.*) A defect in varnish or varnishing giving rise to a mist or bloom which appears upon the bright surface, and dims it wholly or partially. The trouble arises from moisture or a want of ventilation. Can be temporarily cured by rubbing over the surface with a rag moistened in paraffin oil.

Blooming Mills and Rolls (*Met.*) The machinery used in dealing with the bloom of puddled iron.

Blottesque (*Paint.*) Painted in large blots. *Spectator*, January 24th, 1885: "The fashionable blottesque school wherewith modern painters smear their way to 'emolument and oblivion.'"

Blow (*Met.*) In smelting, the forcing of air into the furnaces. In the foundry a blow, or blowhole, is a cavity caused by air being enclosed in the molten metal.

Blower (*Mining*). (1) A jet of natural gas emanating from coal in a mine; (2) blowing machinery for pumping air.

Blowing Engines (*Eng.*) Either rotary machines (*see* FANS) or large pumps, worked directly from the piston rod of an engine. Used for working the air blast. They deliver large volumes of air at a pressure of 2 up to 10 lb. per square inch.

Blowing Off (*Met.*) Driving out the whole of the water in a boiler, in order to expel the sediment.

Blowing Room (*Cotton Spinning*). That department of a spinning mill where opening and scutching (*q.v.*) are carried on.

Blowing Through (*Eng.*) Clearing the pipes and valves of an engine by sending a current of steam through before starting.

Blown Castings. Castings containing a number of blowholes.

Blown In (*Met.*) A blast furnace fully started. This operation takes three or four weeks.

Blown Joint (*Plumb.*) A lead pipe joint made with a blowpipe.

Blown Oil. A fixed oil (*q.v.*) such as linseed or rape oil, which has been treated by being heated and having air blown through it. The process increases the density and viscosity of the oil, and renders it valuable in the manufacture of lubricants, for which purpose it is usually mixed with a mineral oil.

Blown Out (*Met.*) A blast furnace which has been stopped is said to be "blown out."

Blown Sand (*Geol.*) A term applied to the deposits of sea sand which accumulate on the shore just above high water mark in many maritime areas, and form sand dunes. Part of the sand is blown inland in the dry state; but most of it is transported in sea spray driven landward during storms. The water drains back to the sea, and the sand is left. Much rearrangement is afterwards carried out by the action of the wind when the sand is dry.

Blow Off Cock (*Eng.*) A cock at the lowest part of a boiler used for emptying it by blowing off.

Blow Out (*Mining*). A part of a vein which has become decomposed.

Blowpipe. A curved tube with a fine aperture, used to direct a jet of flame on to an object which has to be heated. Used in chemistry for dry tests, and in various arts. In the latter case a portable lamp is frequently combined with the blowpipe, and in this form it is used for soldering by plumbers, electric wire men, etc., and by painters for burning off old paint before applying a new coat. The air current is furnished either by the breath of the operator, by some form of blower or bellows, or by the use of compressed oxygen. The latter furnishes the most intense flame known, and will fuse many of the most refractory substances, being second only to the electric furnace (*q.v.*) in the temperature which it can attain.

Blowpipe *or* **Blowing Iron** (*Glass Manufac.*) A long hollow iron rod about 5 ft. in length and varying in diameter from ⅝ to 2 in. according to the weight of the glass intended to be worked.

Blow Through Valve (*Eng.*) A valve connecting the valve box with the condenser of an engine, used for blowing through (*q.v.*) before starting the engine.

Blubber (*Zoology*). A layer of thick, oily fat beneath the skin of the whale and porpoise. Large quantities of whale oil are obtained from it.

Blubber Oils. A group of oils obtained from the blubber of the whale, seal, porpoise, and dolphin (black fish), *q.v.*

Blue (*Paint.*) One of the primary colours: cf. the colour of the clear sky or the deep sea. The blues used as pigments are practically all compound substances derived either from vegetable or mineral sources. Amongst blue pigments may be mentioned ultramarine, Prussian, French, cobalt, royal, smalt, etc. (*q.v.*)

——, **Alkali.** *See* DYES AND DYEING.

Blue Billy (*Met.*) A ferruginous residue resulting from the roasting of copper pyrites, used as a "fettling" (*q.v.*) in the Cleveland iron district.

Blue Black (*Paint.*) Ivory black.

Blueing (*Eng.*) In tempering steel, the production of the blue tint by heating the metal to about 570° F. Steel springs, pistol barrels, etc., are so tempered.

Blue John (*Min.*) A miner's synonym for FLUOR-SPAR (*q.v.*)

Blue Lias (*Geol.*) A term usually restricted to the bands of argillaceous limestone which occur in the LOWER JURASSIC ROCKS.

Blue Lias Lime (*Build.*) A lime that will set under water—*i.e.* a hydraulic lime. *See* CEMENTS.

Blue Metal (*Met.*) A copper MATT (*q.v.*) containing 60 or 70 per cent. of copper.

Blue Print (*Photo.*) A mixture of a ferric salt and potassium ferricyanide is spread on paper; light produces an insoluble blue compound resembling Prussian blue. The unchanged portion can be washed away, giving (if a tracing is being copied) white lines on a blue ground. To get blue lines on a white ground the paper may be coated with certain ferric salts and developed in a solution of potassium ferrocyanide, and then cleared by an acid bath and washed. This process is less used than the former one, as it involves much more manipulation.

Blue Vitriol (*Chem.*) The common name for crystallised copper sulphate, $CuSO_4 5H_2O$.

—— (*Min.*) A synonym for CHALCANTHITE (*q.v.*)

Bluey (*Plumb.*) A slang name for lead.

Blunger (*Pot.*) A vertical cylindrical machine in which knives are fixed upon a rotating central shaft. The use is to cut up and to amalgamate with water such clays as do not require grinding.

Boarding (*Leather Manufac.*) A process used for light leather for *producing* the natural grain markings on the leather. The skins are boarded up (rolled) with a curved board covered with cork, which grips the damp leather.

Boarding (*Leather Manufac.*) *See also* GRAINING.

Boards (*Bind.*) Pieces of strong strawboard or millboard used to form the covers of books. A book *in boards* has these covered only with paper; if they are covered with cloth, it is *in cloth boards*; if with leather or a like substance, the book is *bound*. Formerly the boards were of thin wood; hence the name.

Boasted (*Build.*) The surface of a stone which has been worked with a chisel called a boaster.

Boaster (*Sculp.*) (1) A tool made of various materials, used in modelling clay or wax; (2) a broad-faced chisel used by masons for dressing the surface of a stone.

Bob (1) The weight on a pendulum, or the weight on a plumbline. (2) A counterbalance weight used in many pieces of machinery.

Bobbin (*Weaving, etc.*) An implement round which thread or yarn is wound in order to be wound off again with facility, as required, in weaving or sewing. It frequently takes the form of a wooden or metal cylinder with a flange or rim at one or both ends.

—— (*Plumb., etc.*) An elongated hard wood ball for driving through lead pipes, in order to prevent denting or collapse while the pipe is being bent or hammered. Also termed a "follower."

—— (*Woollen Manufac.*) An implement on which the yarn is wound either for warping or beaming.

Bobbin Net (*Lace Manufac.*) This is made upon the twist lace machine as invented by John Heathcote, 1809-11. It is a hexagonal-shaped net in imitation of Brussels, and has one system of threads traversed diagonally in both directions, with the result that it does not "run" when cut. Centres of manufacture, Nottingham, Tiverton, Chard.

Bodkin (*Archæol.*) A large pin or pinlike instrument, generally thicker than a pin, used by women for fastening coils of hair.

—— (*Typog.*) A pointed steel instrument used to pick out letters in set-up type.

Body (*Eng.*) Applied to oils. "Body" refers to the consistency or viscosity. An oil which owes its viscosity to resinous substances in solution should not be considered to have "body." A lubricating oil should have good body.

Body (*Typog.*) The shank of a letter.

Body Colour (*Paint.*) (1) Colour which coats or covers the canvas, being opaque by the addition of white instead of being transparent, or used as a wash.

—— *or* **Body of Pigments** (*Dec.*) The property of opacity or power to mask or hide a surface to which a pigment, in the form of a paint, is applied. It is this property which makes white lead so valuable as a paint. Body is sometimes incorrectly termed "covering power" (*q.v.*)

Body of a Work (*Typog.*) The text of a volume, exclusive of preface, notes, appendix, etc.

Boghead Coal (*Min.*) A synonym for TORBANITE (*q.v.*)

Bogie (*Eng.*) A frame carrying two or four wheels, attached by a vertical pivot to the front or back of a locomotive or long truck or car. The bogie can turn on this pivot when the vehicle is going round a sharp curve.

Bogie Engine (*Eng.*) A locomotive with a bogie either under the front or back of the frame of the engine.

Bog Iron Ore (*Min.*) A loose earthy form of LIMONITE often deposited in swampy ground, probably as the result of the decomposition of other iron compounds by decomposing vegetable matter. It is sometimes worked as an ore.

Bohemian Glass. *See under* GLASS MANUFACTURE.

Boil (*Met.*) The stage of the Bessemer process during which the carbon is being oxidised to carbon monoxide.

Boiled Oil (*Dec.*) Linseed oil which has been heated to a temperature of from 210° to 260° C. This increases its "drying" properties or power of absorbing and combining with oxygen. Various driers, such as litharge or manganese dioxide, are usually added in small quantities to the oil while hot to assist the quick drying. Boiled oil is generally mixed with raw oil when used by the painter. Refined boiled linseed oil is lighter in colour than the usual quality, and is valuable for mixing light paints, particularly zinc white (*q.v.*) A simple test for drying qualities is to paint a little of the oil on a watch glass. At the end of twenty-four hours the oil should have formed into a hard, glossy skin. Raw oil at the end of the same period will have remained soft. Unboiled oil is called "raw oil."

Boiler Capacity (*Eng.*) Either the cubical capacity of the boiler or the horse power of the engine it can drive.

Boiler Coating (*Eng.*) A non-conducting coating of asbestos, felt, cement of some kind, or some patented composition placed over boilers to prevent loss of heat.

Boiler Crown (*Eng.*) The top plate of a boiler.

Boiler Explosions (*Eng.*) The sudden bursting or rupture of the plates of a boiler; the serious consequences which ensue are caused not only by the violence with which fragments of iron, masonry, etc., are scattered in all directions, but also by the scalding steam, which proves fatal to persons exposed to it in an incredibly short space of time. Explosions occur through inherent weakness in the boiler itself, due to faulty construction; the use of inferior materials; plates having been corroded or eaten away by the action of the water; or owing

to an excessive increase of pressure caused by carelessness, overworking the boiler, or failure of the SAFETY VALVE (*q.v.*) Strict regulations for the management of boilers are laid down by the Board of Trade, and enforced by official inspectors.

Boiler Fittings and Mountings (*Eng.*) Those parts of a boiler which have to be added after the carcase leaves the hands of the boiler maker.

Boiler Plate (*Eng.*) Ordinary Lowmoor, B.B., or B.B.B. plates (*q.v.*) Steel plates are now much used, fastened with steel rivets, and as they can be made much larger than iron plates, the number of seams and rivets is greatly diminished.

Boiler Pressure (*Eng.*) Varies from 40 or 50 lb. per square inch to several hundreds in modern "tubular" and "water-tube" types.

Boilers. An engine boiler consists of a vessel made of wrought iron or steel plates riveted together at their edges, and is usually of cylindrical form. In the older forms of boiler the fire is contained in an inner tube, from which there may lead one or more flues, which serve the double purpose of conveying away the waste gases and of increasing the heating surface of the boiler.—A CORNISH BOILER (fig. 1) contains one large tube running through the boiler from end to end, carrying the grate at one end, the other end being connected to the chimney. This large tube is frequently crossed by short conical tubes termed GALLOWAY TUBES, which increase the heating surface, and also help to strengthen the large tube through which they run by acting as stays. One of these tubes is shown running through the fire box of the vertical boiler in fig. 3.—LANCASHIRE BOILER (fig. 2): This is similar in outward form to the Cornish boiler, but contains two large tubes running through it.—VERTICAL BOILERS: These are used in small engines, launch engines, fire engines, etc. They contain an internal fire box, as shown in fig. 3. This fire box is frequently crossed by Galloway tubes, one of which is shown in section in the figure. When very great heating surface is required, a device known as a FIELD TUBE is used. This consists of a tube closed at one end, running into the fire box, with a smaller tube open at both ends fixed concentrically inside it. Water can thus circulate through the tube on account of the double passage (*see* fig. 4).—LOCOMOTIVE BOILER: The essential characteristic of the locomotive boiler is the presence of a large number of flues, which are small tubes carrying the furnace gases from the fire box to a smoke box or receptacle communicating with the chimney. A diagrammatic section of a locomotive boiler is given in fig. 5. WATER TUBE BOILERS: In these boilers the fire box is external to the boiler. The latter consists of a very large number of tubes communicating at their ends with vessels intended to contain a certain amount of water and steam. The structure of a water tube boiler will be best understood by reference to the diagrams. Fig. 6 shows the YARROW WATER TUBE BOILER. A is a long cylindrical vessel communicating with two smaller ones, B, B, by a series of tubes, C. In ordinary use the water will reach up to the level shown, and the steam will collect in the space

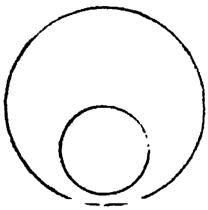


FIG. 1.—CORNISH BOILER.

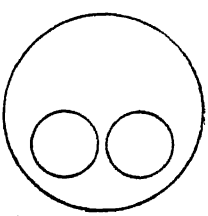

FIG. 2.—LANCASHIRE BOILER.

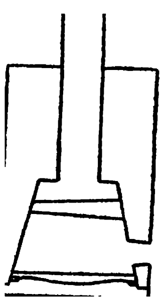

FIG. 3.—VERTICAL BOILER.

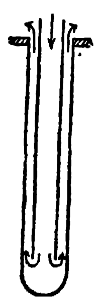

FIG. 4.—FIELD TUBE.

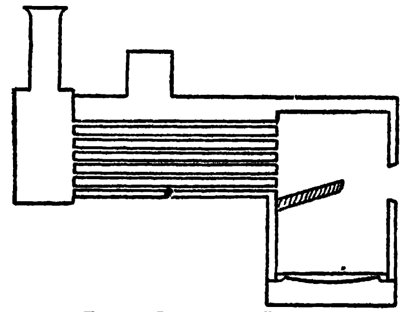

FIG. 5.—LOCOMOTIVE BOILER.

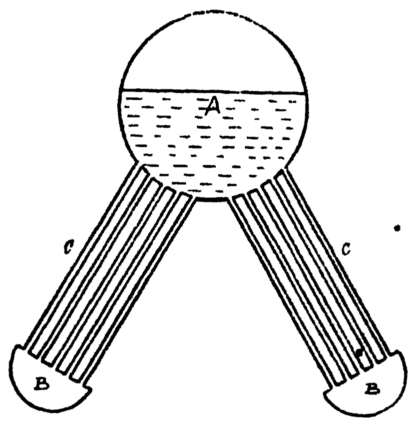

FIG. 6.—YARROW WATER TUBE BOILER.

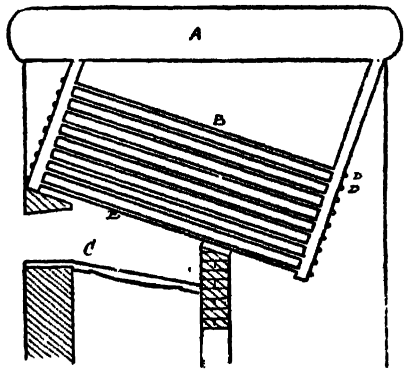

FIG. 7.—BABCOCK & WILCOX WATER-TUBE BOILER.

above. Fig. 7 is the boiler introduced by BABCOCK & WILCOX. A is the vessel where the steam collects; B, B are the heating tubes; C is the furnace. The tubes can be cleaned out by means of removable plugs, shown at D.—The BELLEVILLE BOILER consists of a number of steel tubes arranged in a vertical zigzag, which is spoken of as an "element" of the boiler. Each element communicates at one end with the vessel in which the steam collects, and at the other end with the adjoining element. One element is shown in elevation in fig. 8. In many cases an "ECONOMISER" is added to the Belleville boiler. This consists of a number of elements similar to those of the boiler, fixed in the "up take" or space above the boiler, through which the furnace gases escape. The feed water is caused to become heated in passing through the economiser on its way to the boiler proper.—FLASH BOILERS: These may be defined as small water tube boilers in which there is no vessel to contain a reserve of water and steam. A pump injects a small quantity of water into the boiler at each stroke, and this water is converted into steam almost instantaneously. The supply of steam to the engine is then controlled by regulating the amount of the feed water instead of by throttling the steam. One of the best known types is that of M. SERPOLLET. The tubes in this boiler are compressed, as shown in fig. 9; or in some cases they are twisted or curved after being compressed, as in fig. 10, in order that the amount of heating surface compared to the volume of water contained may be as large as possible. Serpollet boilers and others on a similar principle are used in steam cars on the road. As an example we may take the case of a four-seated car of 6 horse power. The boiler contained 95 ft. of steel tubing, with 25 sq. ft. of heating surface. The whole boiler was only 2 ft. 6 in. long by 1 ft. 6 in. broad, measured outside the case.

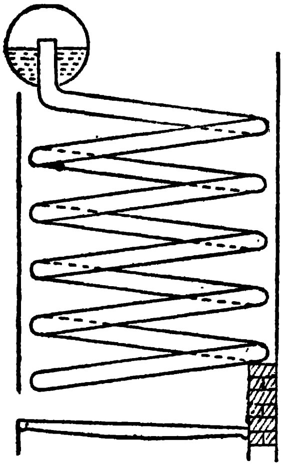

FIG. 8.—BELLEVILLE WATER TUBE BOILER.

9.—SERPOLLET TUBES.

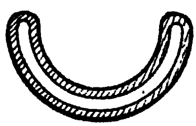

FIG. 10.—SERPOLLET TUBES.

Boilers (*Motor Cars*). These are of the water-tube or the flash types: the former suitable for heavy vehicles, such as steam lorries; the latter for light cars. *See also* BOILERS *and* MOTOR CARS.

Boiler Setting (*Eng.*) The masonry, etc., on which a boiler rests and which forms the flues.

Boiler Smithy (*Eng.*) A forge where the angle irons and other incidental ironwork of a boiler are prepared.

Boiler Stays (*Eng.*) Rods strengthening the shell. In many forms the tubes themselves serve as very efficient stays.

Boiler Testing (*Eng.*) Water is forced in under a high pressure, which is measured by suitable gauges. The use of water instead of steam in testing obviates the danger of an explosion; leakage is detected by a fall of the pressure gauge, and a tear or burst is at once noticed, but it will not be violent nor dangerous to the operators.

Boiler Tubes (*Eng.*) *See* BOILERS.

Boiling. (1) In the ordinary sense, the production of vapour throughout the mass of a heated liquid, which occurs, under normal pressures, at a definite temperature, called the "boiling point"; (2) in metallurgy, the purification of tin by immersing pieces of damp wood in the molten metal. The gases evolved cause the pure metal to collect on the surface, forming "refined tin."

Boiling Point (*Heat*). The temperature at which cavities or bubbles of vapour form within the mass of a liquid. The boiling point is raised by the presence of dissolved substances, and also by increasing the external pressure, and is lowered by diminishing the pressure.

Bole (*Bind.*) A fine kind of clay, containing iron oxide, used to prepare the edges of books for gilding.

Bolection Moulding (*Carp. and Join.*) A panel moulding (*q.v.*) projecting above the surface of the framing, which it decorates. Used chiefly for external doors.

Bollard. A short column fixed in the masonry of a quay for mooring vessels; also a similar column on the deck or bulwarks of the vessel.

Bolognian Phosphorus (*Chem.*) A name given to barium sulphide, obtained by reducing the sulphate by heating it with charcoal. If, after exposure to a bright light, it is removed to a dark place, it shows an orange phosphorescence.

Bolometer (*Elect.*) An instrument for detecting radiant heat. A zigzag grating of very thin platinum foil receives the rays; the rise in temperature produced alters its resistance, and upsets the balance of a Wheatstone bridge (*q.v.*), of which it forms one arm. It detects, rather than measures, radiation; but within certain limits the deflection of the galvanometer may be taken as a measure of the amount of radiant energy received by the grating.

Bolsover Stone. *See* BUILDING STONES.

Bolster (*Architect.*) The return part of the volute of an Ionic capital. *See* BALUSTER, ARCHITECTURE, ORDERS OF, *and* IONIC.

—— (*Eng.*) The part of a punching machine which supports the metal which is being worked upon.

Bolt (*Arms*). An arrow, especially a short, thick arrow that was used with the crossbow; this latter weapon was also termed a "quarrel."

—— (*Bind.*) The fold in the sheets at the head and foredge (top and front) of an "uncut" book.

—— (*Cloth Manufac., etc.*) A roll of woven fabric, varying in length according to the fabric, being in some cases 30 yards, in others 28 ells.

—— (*Eng., etc.*) (1) A general term for the screw with fixed head and loose nut used in fastening up metal or wood work; (2) an appliance for fastening a door, consisting of a piece of iron which moves

longitudinally through guides on the door, so that it can be shot into a socket in the doorpost; (3) that part of a lock which springs out and enters the receptacle or "keeper."

Boltant, *also* **Bolting** (*Her.*) Said of hares and rabbits when running.

Bolting (*Met.*) Closing up the "tap hole" of a cupola furnace with clay in order that a fresh amount of molten metal may accumulate.

Bolt Machine (*Eng.*) A machine for forging the blanks of bolts, ready for screwing or cutting the thread.

Bombardon. *See* MUSICAL INSTRUMENTS—WIND, BRASS.

Bombylios. A small antique vase with a very narrow neck.

Bond (*Build.*) The method of laying bricks or stones so that the vertical joint below is covered by the brick or stone above it. *See* DUTCH, ENGLISH, FLEMISH BOND, etc.

Bond Block (*Build.*) A bond in which a number of headers (*q.v.*) are laid side by side.

Bonder (*Build.*) A stone going threequarters through the thickness of a wall.

Bond Timber (*Carp.*) Timber fixed by being built in walls; wall plates, etc.

Bone (*Zool.*) The substance forming the skeleton of the body; it is composed of inorganic and organic matter in the proportion of 67 parts of the former to 33 parts of the latter. The inorganic matter consists of calcium phosphate, carbonate and fluoride, and magnesium phosphate. The organic matter is cheifly collagen, which on boiling is converted into gelatine. Bone is traversed by a network of canals carrying bloodvessels. The bones of various animals, chiefly those of the ox, are used in turning and in cutlery; also in the manufacture of charcoal or bone black. Bone ash is used in assaying. Bone preparations form excellent manures, owing to the phosphate of lime which they contain. *See also* WASTE PRODUCTS.

Bone Ash. The residue that remains when bones are strongly heated in air: a white powder consisting of calcium phosphate ($\frac{4}{5}$) and magnesium phosphate, calcium carbonate, calcium oxide and calcium fluoride, the last four substances together forming about $\frac{1}{5}$th of the bone ash.

Bone Beds (*Geol.*) A name which is now usually restricted to any band of rock which yields an unusually large number of remains of vertebrates, which in most cases are those of fish. One bone bed occurs in the Ludlow Rocks, near the town of that name; another occurs in the LOWER CARBONIFEROUS rocks of the coast of Fife, south of Kirkcaldy; a third is found in the Rhætic Beds near Aust, on the Bristol Channel.

Bone Black. The same as animal charcoal (*q.v.*)

—— (*Paint.*) A pigment made from carbonised bones. It mixes well with water and oil, and is quite permanent. The better grades of bone blacks are often sold as ivory black (*q.v.*)

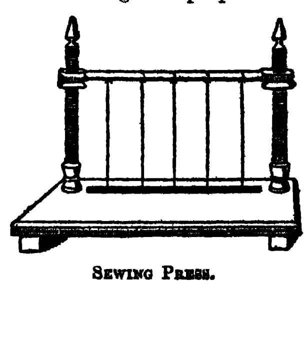
Bone Oil. When bones, freed from fat, are distilled in iron retorts, gases are given off, and a distillate is obtained which separates into a watery part, rich in ammonia and its compounds, and an oil called bone oil, having a disagreeable smell and a dark brown colour. This oil is a complex mixture of Amines (*q.v.*), Nitriles (*q.v.*), Pyrrol (*q.v.*), Pyridine and its homologues (*q.v.*), Quinoline (*q.v.*), and other less important constituents. *See also* WASTE PRODUCTS.

Bone Turquois (*Min.*) Fossil osseous remains coloured by phosphate of iron. Also called ODONTOLITE. It is used as a substitute for TURQUOIS.

Boning Staves *or* **Rods** (*Surveying*). Used in levelling. Staves, usually 3 ft., furnished with T-head.

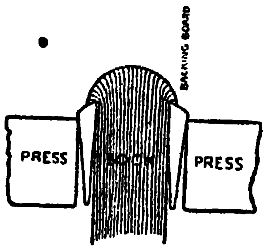
Bonnet (*Eng.*) (1) The cap or cover of the valve box of a pump; (2) the cover or hood of a forge; (3) the cover placed over the engine of a motor car, usually pierced with parallel slots to allow the free play of air round the engine to aid in the cooling; (4) any case or cover in engineering.

Bookbinding. Before the invention of printing, the manuscript books, which were chiefly of an ecclesiastical character, were bound by the monks. Owing to the great amount of labour involved in producing these books, they were highly valued, and the binding or cover of a book was frequently richly ornamented with gold and silver work—sometimes even jewelled. Binding in this style is known as "Byzantine." By the end of the fifteenth century bookbinding had become an art by itself, although it was probably in the workshops of the early printers themselves that binding was executed. In addition to royal patrons of the art, the most celebrated bibliophiles or collectors of books during the sixteenth century were Maidli, Grolier, and De Thou; and doubtless the books forming their respective libraries were bound immediately under their supervision. Howbeit, in these and other early instances, bindings are known by the names of their collectors and not by the names of the actual binders. Amongst celebrated binders employed in the royal service in France, where the art was so ardently cultivated in the sixteenth century, were Nicolas and Clovis Eve. In the seventeenth century the most celebrated artists in the profession were Le Gascon and Du Sueil, the former noted for his *pointillé* work—innumerable minute dots in geometrical arrangement. Later come Padeloup and Derôme. In England one of the binders in the reign of Henry VII. whose name has been handed down is Julian Rotary, and in the following reign there was one John Reynes. Two and a half centuries later we come to Roger Payne, one of the best English binders; while later still Baumgarten, Kalthoeber, Bohn, and others have left examples of work which place them in the first rank. To come to present-day work, a book properly bound passes through twenty-three distinct and different processes, but each process might be again divided and subdivided. The book, when it comes from the printers, is first folded, or, if it has been previously bound in cloth, it is "pulled" or taken to pieces. Next it is collated—that is, the sheets arranged in proper order and ascertained to be perfect, and the plates, if any, pasted in their places. It is then rolled or pressed, and afterwards sewn. In sewing, each sheet is fastened to cords by a thread going along inside the fold of the back, the ends of these cords being

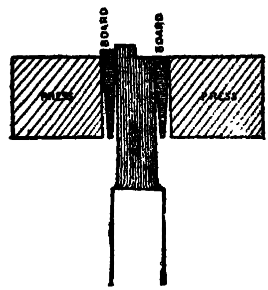


SEWING PRESS.

afterwards laced into the boards. Next, folded papers, plain or coloured, are placed on the front and reverse side, being edged on with paste. When these are dry, the cords are ravelled out and slightly scraped. The book is now put into a laying press between a pair of firm millboards, the back standing up about 2 in. above the cheeks of the press. Three or four books of the same size may be put in at one time. The back is then glued over with thin glue, and the book taken out of the press and left to dry. It is next rounded and backed. For backing it is placed in the laying press, between a pair of bevelled boards, called backing boards, the rounded back standing up above the boards and showing a margin of the end papers as wide as the thickness of the millboards about to be used. The press is then screwed up tightly, and the book is backed by striking the back with the hammer, gently at first, commencing in the middle and beating the back down to the bevelled boards, first on one side, then on the other, the back being finally modelled into a good shape. The next process is to cut the boards. Having been roughly cut with the large shears, somewhat near the size of the book, they are squared with the plough just a little larger than it is intended to cut the book—the standing rule in good work being to leave every book as large as possible. When the boards are cut to size, they are placed one on each side of the book, and a mark is made where the cords come. Then holes are pierced through these marks, the board is turned over, and other holes pierced about a quarter of an inch away from the first holes. The ravelled out cords or slips are then pasted and twisted to a point with the finger and thumb, so that they can easily be passed through the holes—in at the first hole and out at the second. They are then drawn tight and the surplus ends cut off. The next step is to rivet the cord by hammering it smooth on the knocking-down iron—an iron casting with an even surface made to fit in the laying press. The book, after being rounded up and put into good shape, is put into the standing press, screwed up as tightly as possible, and generally left in till the next day. Before it is taken out of the press the back is pasted over with thin paste and rubbed smooth, then wiped dry with a handful of paper shavings. Some perform this operation as soon as the book is put into the press; but when the pressure is removed from the mass of paper forming the book, it naturally rises somewhat, in consequence of being dry, and frequently the back cracks, whereas if the back be moist when the pressure is taken off, the expanding mass of paper conforms to the new conditions upon being taken out of the press, without any danger of cracking. The book is next cut. First, the top edge, called the head; next, the bottom edge, called the tail; and lastly, the front edge, called the foredge. The cutting is done by lowering the front board as far down from the head as it is intended to cut, placing a thin piece of millboard between the back board and the book. Then it is lowered into the laying press until the top of the front board is even with the cheek of the press, which is then screwed up tightly, and the book is cut by working the plough backwards and forwards, the operator closing it as he pushes it away and opening it as he draws it towards him. The same operation is repeated in cutting the tail. In cutting the foredge, two trindles—flat pieces of steel or wood about an eighth of an inch thick—are placed between the back and the boards. The book is then lifted up between both hands, and brought down with some force upon the cheek of the laying press; the back, striking the press, becomes flat, the trindles keeping it in this position. A cutting board is then placed on each side, that on the front side being even with the line to be cut through, and that on the back raised a little above. The position for placing the cutting boards is regulated by drawing a line with a sharp point or pencil on the end papers along the front edge of the boards on each side, and the book is cut as much below this line as it is desirable to have the boards projecting beyond. It is then lowered in the press, after taking out the trindles, bringing the front cutting board even with the cheek of the press, and cut with the plough in the same manner as the head and tail. When taken out of the press, the back resumes its round shape again, and the foredge will be the reverse of the back. The next process is to decorate the edges. They may be sprinkled red, brown, or blue, or coloured red or yellow, or indeed any colour; or they may be marbled or gilded. Next, the book is headbanded. A very narrow strip of stiffened vellum or glued cord is fastened to the back of top and bottom edges by means of silk or cotton of various colours being twisted round the same and fastened to the back at short intervals. Then the back is lined with brown paper and thin strips of leather glued on to form bands, or it is simply glued over, and is now ready for covering. This is perhaps the most critical operation in bookbinding. The leather having been cut to the size, the edges are pared with a sharp knife just where they will be turned in by the headband—not all round. The cover is now pasted smoothly all over, and allowed to soak for a short time while the boards are being placed in position, etc. It is then placed upon the workboard, pasted side uppermost, and the front side of the book laid upon it, care being taken that an even margin of leather is left round the three edges. Then the other end of the cover is lifted up and drawn over the back edge, being smoothed out carefully with both hands. The board is now lifted and the margin of leather on the foredge is turned over on to the inside of the board with the forefingers and thumbs of both hands. The book is then turned over and the operation repeated on the other side. Next, the book is held in the left hand and the boards allowed to fall open on the workboard, and, being brought to the edge of this, the margin of leather, head and tail, is also turned over on to the inside of the boards with the finger and thumb of the right hand, beginning at the headband, in which place it is turned over on to itself; and to accomplish this it is necessary to raise the book somewhat away from the boards. The edges of the boards are then made



AFTER BACKING.



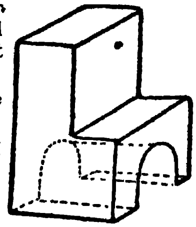
SECTION OF BOOK AND PRESS. FOREDGE PARTLY CUT.

smooth and sharp with the folding stick. There will then be some surplus leather at the corners. To get rid of this it is pinched together with the finger and thumb, or both thumbs, and then cut through with the shears and smoothed down with the folding stick, one edge lapping slightly over the other. When dry—generally the next day—these two layers of leather are cut through with a sharp knife at an angle of 45, the surplus pieces taken away, and the two sharp edges pasted and carefully joined. The next process is to trim the inside margin of leather round the three edges of the boards, and fill in the centre space with thick paper, making it level with the rim of leather. The end papers are then pasted down to the boards, care being taken to leave an even margin of leather round the three sides: and the book is bound. Then follows the decoration, or, as it is called, the finishing, the only *necessary* part of which is the lettering. The finisher's first process is marking up. He makes certain marks upon the leather to guide where lines or tools are to be impressed. Then the leather is carefully washed over with vinegar if it be morocco, or paste water if it be calf; and when dry, a coating of albumen is laid on wherever the gold is to appear. If the back is to be "full gilt," then the albumen is sometimes put on with a sponge—always, in the case of calf; if only lines each side of bands, then the albumen (glacé) is put on with a camelhair pencil. When dry, the gold is cut on the gold cushion to the size required, and the part to be finished is well greased with oil, lard, or vaseline, according to the leather. Then the gold is taken off the cushion with a pad of cotton wool, which has been previously dabbed on the hair to cause the gold to adhere temporarily to the pad, and then placed on the part about to be finished, and well dabbed down with the pad. The book is now put into the finishing press, the back standing out a little above the cheeks. The lines and flower or scroll tools, having been heated at the stove or gas pan, are now impressed on the back over the gold. Afterwards the surplus gold is wiped off. The book is now lettered. The panel or part where the lettering is to appear having been glaired and greased, the gold leaf is taken up with the pad as before, and laid all over it. Then, the book being in the press with the back standing a little way out, the head away from the workman, a fine thread is drawn across the gilded panel. This makes a fine dark line upon the gold. As many lines are drawn as there are lines of lettering. The letters, having been heated at the stove, are impressed on the leather singly, the top of the letter being placed *just under* the line. Great care is necessary to ensure an equal pressure upon each letter. The lettering may be done with type. In this case a line of lettering is completed in one impression. The surplus gold is wiped off with the gold rag, and the surface cleaned with indiarubber. The sides of the book may be quite plain or finished elaborately. In the latter case it is usual to impress with all the tools before washing up for glairing, and glair with a camelhair pencil over the impressions. The gold is then laid on with grease, and the tools impressed through the gold—surplus gold wiped off as before. The whole is then polished with a moderately warm polishing iron. The book is then placed in the press between japanned plates or bright smooth tins, and left in, if convenient, till the next day. Ordinary cloth bindings, in which books are issued by the publisher, are much simpler than the above. In these the book is sewn by hand or machine, glued up and rounded and generally backed, but not always or necessarily. It is then pasted into a case which has been made quite separately, and in which it is simply held by the end papers and a thin strip of cotton called mull.—R. De C.

Boom (*Eng., etc.*) Any long beam, especially the long, solid parts of a built-up girder.

Booster (*Elect. Eng.*) A subsidiary dynamo, used to keep the voltage at some part of the circuit remote from the principal dynamo, up to some constant value. The purpose of employing a booster is to obtain independent control of the voltage at some point or points of the circuit without alteration of the voltage of the main dynamo. The booster is often so adjusted as to automatically maintain constant voltage at some distant point of the circuit; often also to provide varying voltage, as for storage battery work.

Boot Boiler (*Build.*) A boiler fitted in a range. It is shaped like a boot, with the top part at the back of the fire.



Boot Boiler.

Boracic Acid (*Min.*) Native boracic acid occurs as a scaly crystalline deposit around fumaroles, marking the subsidence of volcanic activity in a district. The crystals are minute, of the triclinic system, and give a peculiar unctuous impression when rubbed between the fingers. From Lipari, Tuscany, Sienna, Atacama, etc. Composition: $B(OH)_3$. *See also* Boron Compounds (*Chem.*)

Boracite (*Min.*) A borate and chloride of magnesium, $6MgO . MgCl_2 . 8B_2O_3$ (boracic acid = 62·6, magnesia = 26·8, magnesium chloride = 10·6 per cent.) It occurs in cubic crystals of considerable hardness embedded in Anhydrite, in Hanover; it also occurs massive (*q.v.*) in the salt mines of Stassfurt.

Borates (*Chem.*) Salts of boric acid (*q.v.*)

Borax (*Min.*) Sodium biborate, $Na_2B_4O_7 . 10H_2O$; boracic acid, 36·6; soda, 16·2; water, 47·2 per cent. It crystallises in prisms of the monosymmetric system; it is largely used as a flux (*q.v.*) and in the manufacture of glass and of artificial gems. It occurs chiefly in Thibet (whence it is exported as Tincal), Persia, Tuscany, Peru, and various parts of North America. *See also* Boron Compounds.

Bordering Wax (*Engrav.*) A composition employed to make a raised border or rim round a plate of metal so as to retain the acid used for biting in during the process of etching.

Bordure (*Her.*) A band which entirely surrounds the shield, and is one-fifth of the field in width: the mark of difference of a younger son.

—— **Compony** *or* **Gobony** (*Her.*) Is composed of a metal and colour alternately.

Bore (*Eng.*) The internal cavity of a pipe or hollow cylinder.

—— (*Marine*). Any very marked and sudden rush of the tide up an inlet.

Boring (*Eng.*) Making, or finishing, a circular hole or "bore."

—— (*Mining, etc.*) A small hole, made by a drill of some form, to ascertain the nature of rocks below the surface, or for introducing a blasting charge.

Boring Bar (*Eng.*) A long rotating bar carrying a "boring head" or holder for the tool used in boring circular holes. In some cases the head can "traverse" or move along the bar; in others, the head is fixed to the bar, and the work has a slow longitudinal motion to produce the "feed."

Boring Machine (*Eng.*) Any machine for boring or for driving a boring bar. A self-acting lathe can be utilised as a boring machine by mounting and rotating the boring bar between the centres, and bolting the work to the saddle of the slide rest.

Boring Tool (*Eng.*) A tool resembling a turning tool mounted on a boring head and bar; sometimes applied to some form of drill for wood or metal. *See* BORING BAR, DRILL.

Borneo Camphor. *See* CAMPHOR.

Bornite (*Min.*) A synonym for ERUBESCITE (*q.v.*)

Boron, B. (*Chem.*) Atomic weight, 11. This element is not found native, but occurs in various combinations in the minerals boracic acid, borax, boracite (*q.v.*), ulexite ($NaCaB_5O_9 . 8H_2O$), priceite ($5CaO . 6B_2O_3 . 9H_2O$), pandermite, datholite, etc. It is a light maroon-coloured powder; burns at a high temperature in air, forming boron oxide (B_2O_3) and boron nitride (BN); latter compound also formed when it burns in nitrogen, which it does at a high temperature. It is a very powerful reducing agent, reducing metallic oxides when heated with them more readily than carbon. It is obtained by heating the oxide with magnesium powder at a high temperature and treating the product in succession with water, hydrochloric acid, water, alcoholic potash, water, hydrofluoric acid, water; once more heating with a little oxide and again treated as above. Said to have been obtained crystallised, but crystals probably impure. It is a non-metallic element belonging to the aluminium group in the periodic system.

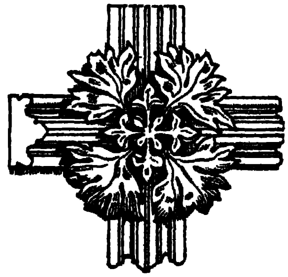
Boron Compounds. BORON HYDRIDE, BH_3, a gas, not known pure; burns with green flame, and obtained when alloy of boron and magnesium is treated with hydrochloric acid. BORON NITRIDE, BN, an infusible white powder obtained as under boron and also by heating anhydrous borax with ammonium chloride. It is decomposed by steam, giving ammonia and boric acid; according to some this is the source of the boric acid of the hot springs from which the acid is obtained. BORON OXIDE, B_2O_3, a white hygroscopic solid obtained by heating boric acid. Heated with salts of metals, the acid of the salt is expelled and the oxide dissolves in the boric oxide, often giving a characteristic colour; hence the use of borax in testing by the "borax bead." BORIC ACID, H_3BO_3, crystallises in plates; is soluble in water. On careful heating gives first metaboric acid, HBO_2, and then pyroboric acid, $H_2B_4O_7$. It is one of the weakest acids; it turns turmeric paper brown. It gives a green flame in the Bunsen burner. A solution in glycerine, called boro-glyceride, is used in medicine as an antiseptic. Boric acid is an antiseptic, and is much used as a food preservative. It is obtained by condensing the jets of steam (*soffioni*) of volcanic origin, which arise from the ground in parts of Tuscany. The steam contains traces of boric acid. The condensed steam is evaporated by the natural heat of the *soffioni*. It may also be obtained by acidifying a strong solution of borax with hydrochloric acid. BORAX, $Na_2B_4O_7 10H_2O$, a white crystalline solid soluble in water. Solution is alkaline. Readily decomposed by acids. It is an antiseptic. Extensively used as a preservative and in making glazes of many kinds. It is a derivative of pyroboric acid.

Bort (*Min.*) A black massive variety of diamond. A native form of carbon. It is useless for jewellery, but is very extensively used in the cutting and polishing of gems and in rock boring, the boring tools being armed with fragments of it. From South Africa, India, Brazil, etc.

Bosh (*Forging, etc.*) A trough in which "bloomary" tools are cooled. The same name is used for the trough in which hot ingots of copper are cooled.

Boshes (*Met.*) *See* FURNACES.

Boss (*Architect.*) An ornament, usually carved, formed at the intersection of the ribs of either a vaulted or a flat ceiling. The same name is also given to the ornament which frequently terminates a dripstone. *See* RIB AND PANEL VAULT *and* HOOD MOULD.



BOSS (DECORATED).

—— (*Bind.*) A metal ornament fastened on the covers of books either for decorative purposes or to preserve them. In early times the "umbo," a round knob, occupied the centre of the cover.

—— (*Eng.*) (1) The central part of a wheel, etc. (2) A projection intended to carry a shaft, projecting pin, or other added part of a machine.

—— (*Gasfitting*). A brass ferrule with an internal thread to screw a gas tap into.

Bossing (*Plumb.*) To work sheet lead into trays, gutters, and cesspools out of one piece of lead by turning up the sides, ends, etc., without cutting, soldering, or burning.

Bossing Mallets. Round tapered mallets for "bossing up" sheet lead or hammering it into any required shape.

Bossing Up (*Eng.*) Forming a raised part on sheet or solid metal by hammering or forging.

Böttcher, *also* **Böttger Ware** (*Pot.*) A hard ware like red jasper, manufactured at Meissen, Saxony, polished by the lapidary's wheel, and called after the manufacturer, Johann Frederick Böttger (1682—1719), who also discovered the method of making true hard porcelain in imitation of the Chinese.

BÖTTCHER WARE MARK.

Bottega. Italian word equivalent to "shop"; applied to the place where Italian artists used to paint their pictures and instruct their pupils.

Botteroll, *also* **Chape** *or* **Crampelle** (*Her.*) The piece of iron protecting the point of a sword or dagger sheath.

Bottle Glass (*Glass Manufac.*) This is manufactured from a mixture of the silicates of aluminium, calcium, and sodium which are readily fusible; but the glass is deficient in purity and lustre.

Bottle Jack (*Eng.*) A light screwjack (*q.v.*) whose external form resembles that of a bottle.

Bottle Nose Drip (*Plumb.*) A drip or step in roofwork, formed with a rounded edge.

Bottle Nosed Step (*Build.*) A step with a rounded edge and end.

Bottling Up (*Eng.*) The collection of steam in tubes or pipes when it is being produced too fast to escape to the steam chest or spaces above the water level of a boiler.

Bottom Bars (*Lace Manufac.*) A series of steel bars that work in a lower position than the ordinary or "top bars." They are used to measure the capacity of the machine in the production of "design."

Bottom Board (*Mould.*) A board used to hold up the lower part of a mould while sand is being rammed in round the pattern.

Bottom Bracket (*Cycles*). *See* CYCLES.

Bottom Card (*Eng.*) An indicator diagram (*q.v.*) taken from the lower end of a cylinder.

Bottom Face (*Mould.*) The part of a mould or casting which is at the bottom during the operation of casting. The bottom face is always the soundest part of a casting.

Bottoming (*Eng.*) The rubbing of the points of one gear wheel into the bottom of the spaces between the teeth of the other wheel; prevented by allowing sufficient bottom clearance.

Bottoming Tap (*Eng.*) A tap (*q.v.*) with the thread carried right to the end, in order to cut a thread right to the bottom of a hole.

Bottom Rail (*Carp. and Join.*) The lowest rail of a piece of framing, door, sash, gate, etc.

Bottoms (*Met.*) The residual alloy containing various impurities when fine metal (*q.v.*) has been roasted in the manufacture of copper.

Bottony, *also* Botoné (*Her.*) *See* CROSS TREFFLED.

Boulder Clay (*Geol.*) Properly applied to the clay which was formed by the direct action of ice during the Age of Snow, and which contains a heterogeneous mixture of stones which have been derived from many sources and are quite unsorted in regard to size. Many of the stones or boulders show the striæ characteristic of glacial action. Most boulder clay is now regarded as having been formed englacially—*i.e.* as representing material which was formerly dispersed throughout the lower part of the ice, and has been melted out of it as a kind of sediment.

Boulders (*Geol.*) A term somewhat loosely applied to any large blocks of stone which have found their way to some distance from the parent rock. Those which have been detached by weathering and have travelled downhill under the influence of gravitation are often usefully distinguished as TUMBLERS; and the term BOULDER is applied by the best authorities only to stones whose transportal has been effected by the agency of ice, more especially during the Age of Snow or the Glacial Period.

Boulevard. Originally meant the bulwark or rampart of a fortified town; now used of an avenue or of a walk encircling a town.

Bourdon's Gauge (*Eng.*) The instrument for measuring steam pressure. It consists of a length of tube of oval section closed at one end and bent into a curve. On steam being admitted, the tube tends to straighten itself, and the amount of movement, which is shown by means of a pointer and a dial, indicates the pressure of the steam.

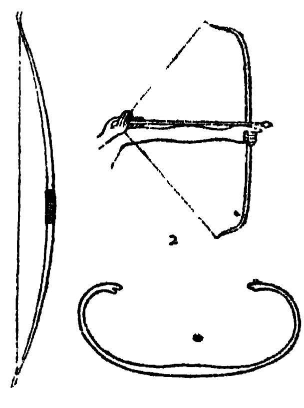
Bourgeois (*Typog.*) Type one size smaller than long primer and one size larger than brevier.

Bournemouth Beds (*Geol.*) Middle Eocene strata of marine origin, typically developed near the town of that name on the South Coast of England. They have yielded an important suite of fossil plants.

Bournonite (*Min.*) A sulphide of copper, lead and antimony, $3(PbCu_2)S . Sb_2S_3$; copper = 12—15, antimony = 24—29, lead = 39—43, sulphur = 18—20 per cent. Also called ENDELLIONITE, WHEEL ORE, or RADELERZ. The latter name is from the spokelike arrangement of the twinned rhombic crystals. Sometimes massive. Cornwall, Saxony, Harz, Chili, Bolivia, etc.

Bovey Tracey Beds (*Geol.*) Beds of lignite, occurring in Devonshire, which have yielded an extensive suite of vegetable remains, the general facies of which indicates that they are of late Oligocene or early Miocene age.

Bow (*Arms*). The bow has been used as a weapon of war and for purposes of sport as far back as there is any record, though naturally it varied greatly in shape. Among ancient nations the Assyrians, Egyptians, Parthians, Scythians, Persians, Thracians, and Cretans were most addicted to this weapon. In the Roman army the bow did not form part of the equipment of the regular legionaries. It was in the hands of the English archers, however, during the period extending from Edward III. to Henry V. that the bow reached its greatest perfection as a weapon of warfare, the deadly "cloth-yard" shaft doing terrible execution in the battles in which the English participated. Archers formed part of the English army long after the use of gunpowder was introduced—that is to say, down to the time of James I.; and Charles I. attempted to revive archery for purposes of warfare. At the present day the Persians, Tartars, Chinese, the Bushmen of South Africa, the South Sea Islanders, and the South American Indians are amongst those who use the bow either for sport or warfare.



1 ENGLISH BOW. 2. EGYPTIAN BOW. 3. PHRYGIAN BOW.

Bow China. The Bow China Works were established about the year 1743 at Stratford-le-Bow, near London, under the management of Thomas Frye, a well known mezzotint engraver. The factory and business were sold to Mr. Duesbury, of Derby, in 1775. Bow China is interesting, but it never attained the high standard of beauty and excellence achieved by Worcester, Chelsea, or Derby. A special feature of Bow China is its soft and creamy glaze. Bow figures, of which a large quantity were produced, are quaint in style, and the colouring is frequently clear and brilliant. For Pottery Marks, *see under* POTTERY.

Bow Compasses. Small draughtsman's compasses, in which the legs are connected by a stiff but flexible band of steel instead of a hinge. The angle to which the compasses are opened is controlled by a screw. Also termed SPRING BOWS and SPRING COMPASSES.

Bow Drill (*Eng.*) A light drill rotated by a string which is wound round a bobbin on the drill shaft, the ends of the string being attached to a bent bow of wood or steel.

Bowed (*Her.*) Bent like a bow: embowed.

Bowling Iron (*Met.*) Iron produced by the Bowling Company, Yorkshire; resembles Lowmoor iron in quality.

Bows. *See* BOW COMPASSES.

Bow Saw. A narrow saw fixed to a wooden frame, in which a twisted cord keeps the saw in tension. Used for cutting curves.

Bow's Notation *or* **Henrici's Notation** (*Eng.*) A method of denoting forces in graphical calculations: specially useful in dealing with reciprocal figures. *See* GRAPHIC STATICS.

Bowstring Girder (*Eng.*) A built-up girder with one straight boom, to the ends of which a curved boom is attached, the two thus forming an arc and its chord; the space between the straight and curved parts is crossed by latticework to increase the strength of the structure. A good example exists in the girders by which the cantilevers are connected together in the Forth Bridge.

Bowtell (*Architect.*) A round moulding used in Gothic architecture. The old English term was "boltell," and the moulding was probably so called because of its resemblance to a bolt. *See* ROLL MOULDING, SCROLL MOULDING, *and* KEEL MOULDING.

Box Calf (*Leather Manufac.*) Calf skins tanned by means of chrome salts, called "box" by reason of square markings on the grain: produced by rolling the skin, when in a damp state, from tail to nose and then from flank to flank.

Box Coupling (*Eng.*) A hollow cylindrical coupling or joint fitting over the ends of two pieces of shafting and connecting them so that they rotate together.

Box End (*Eng.*) The end of a connecting rod which is forged solid, a slot being made to receive the brasses, instead of their being attached by a strap keyed on.

Box Girder (*Eng.*) A hollow girder, built up of four strips of iron which form a cavity of rectangular section.

Box Gutter (*Build.*) A gutter with vertical sides, parallel in width the whole of its length.

Box In (*Typog.*) A term indicating that rules should be placed round as a border.

Boxing Shutters (*Carp.*, *etc.*) Window shutters that fold back into boxes.

Boxing Up (*Pattern Making*). Building up large patterns from boards instead of cutting them from the solid wood.

Box Metal (*Eng.*) Alloys used for bearings, including brass, gunmetal, white metal, etc.

Box Nut (*Eng.*) A nut with a cover which protects the end of the bolt from injury, rusting, etc., in exposed situations, thus preventing jamming of the nut on the end of the bolt.

Box of Tricks (*Cotton Spinning*). *See* BUILDING MOTION.

Box Spanner (*Eng.*) A spanner for turning nuts which lie in a cavity sunk below the general surface of the metal.

Box Stones of East Anglia (*Geol.*) Septarian nodules which contain water in cavities in the interior. The cavities are due to partial solution of the original material.

Boxwood. *See* WOODS.

Boxwood for Engraving. Small narrow blocks of the wood are used; for large engravings the blocks are fastened together by size and screws. In the case of woodcuts intended for illustrated papers, and where expedition is necessary, the blocks can be separated and distributed to different engravers.

Boyle's Law (Mariott's Law). The volume of a gas is inversely proportional to the pressure if the temperature remain constant. This law is true only for a PERFECT GAS (*q.v.*), but it is approximately obeyed by all gases when not too near their point of condensation.

Boyle's Valve (*Ventilation*). This valve is designed to act as an outlet for the vitiated air of rooms. It is an iron box arrangement provided with valves, which are suspended on rods. The ventilator is fixed in the chimney. Back draught is prevented by the automatic closing of the valves when the pressure is greater in the chimney than in the room.

Brace (*Eng.*, *etc.*) A rod or bar connecting two points in a structure for the purpose of strengthening or stiffening it. It is always in tension; a similar rod in compression is termed a strut.

—— (*Tools*). A cranked tool used for holding and rotating a drill or bit.

—— (*Typog.*) The sign ⏞, used chiefly for connecting words, lines, or staves of music.

Bracelet (*Cost.*) A band worn upon the wrist or arm, sometimes plain, but more often enriched by the graver and by the addition of precious stones. Bracelets were amongst the earliest of personal ornaments, and although now worn almost exclusively by women, they were in earlier times worn by both sexes of the better class, and were very common amongst the earlier inhabitants of Britain.

Brachydiagonal (*Min.*) The shorter of the two horizontal axes in the Orthorhombic system (*q.v.*) It is designated by the letter *a*, and is usually regarded as extending from front to back when the crystal is correctly oriented.

Brachydome (*Min.*) The face of a prism of the Orthorhombic system which has its axis coincident with the brachydiagonal (*q.v.*)

Brachypinacoid (*Min.*) A face normal to the macropinacoid.

Bracket (*Eng.*, *Build.*, *etc.*) A term of very wide use, applied to portions of structures used for stiffening or supporting some other part.

—— (*Carp. and Join.*) In staircase work the curved pieces planted (*i.e.* fixed) on the outside of a cut string; also a term of very general application in woodwork.

——, **Lamp** (*Cycles and Cars*). A projection, either fixed or moveable, to carry a lamp, the latter having a socket which fits the projecting part of the bracket.

Bracklesham Beds (*Geol.*) Marine beds of Middle Eocene age, typically developed on the coast of Sussex.

Bract (*Botany*). A leaf in whose axil (angle) a flower arises. The term is, however, loosely used, and may be applied to any specialised leaf in the vicinity of the flower.

Bradawl. A tool for making holes for brads or small nails.

Bradford Clay (*Geol.*) One of the subdivisions of the Oolites, well known on account of the excellently preserved fossils it yields in the typical locality. It forms the lowest member of the Middle Oolites, and it underlies the Coralline Oolite or the local equivalent of that rock.

Brake (*Eng., etc.*) Mechanism for controlling or slowing down any machine. It usually acts on a wheel. A block cut to fit the circumference is forced into close contact by levers or screws, or a flexible band is pulled into close contact with the rim of the wheel (band brake). *See also* CYCLES, MOTORS, WESTINGHOUSE BRAKE, PNEUMATIC BRAKE, *etc.*

—— (*Plumb.*) The angles of the projection of a wall in a gutter around which the lead is bossed when a lead gutter is formed.

Brake Drum (*Eng.*) The cylindrical portion on which the brake block or brake band acts.

Brake for Measuring Power. *See* DYNAMOMETERS, MECHANICAL.

Brake, Friction (*Mechanics*). *See* DYNAMOMETERS, MECHANICAL.

Brake Horse Power, B.H.P. (*Eng.*) The power (*q.v.*) developed by an engine or motor, which is absorbed by a brake dynamometer; distinguished from the indicated horse power (*q.v.*) as being the amount of power which the engine can put out for useful purposes.

Brake Shoe (*Eng.*) A brake block; the portion which comes into actual contact with the wheel on which the brake is acting.

Bramah's Press (*Eng.*) *See* HYDRAULIC PRESS.

Bramley Stone. *See* BUILDING STONES.

Branch Drains (*Sanitation*). These are tributaries conveying the sewage, slop, and waste waters to the main or common drain. A manhole should be constructed where the branches join with the main drain. As much care is necessary in the laying and jointing of branches as in the case of the main drains.

Brandering (*Carp. and Plast.*) Pieces of wood about 1 in. square fixed to large timbers that have to be plastered. On these pieces of wood the laths which carry the plaster are nailed.

Brands. (1) Marks used to distinguish the qualities of various materials; they are very numerous, and must be sought in the directories to the various specific trades to which they refer. (2) Iron letters used for impressing marks on wood by heating and pressing on the wood.

Brandy. A spirit made by distilling wine. It contains about 48 per cent. of alcohol by volume, and small quantities of higher alcohols and the ethyl esters (*see* ESTERS) of propionic, butyric, venanthylic, and valerianic acids. The colouring matter is tannin (pale brandy) or caramel (brown brandy). Inferior brandies are not made from wine, but are manufactured from recipes of various kinds. In France the finest brandy is known as "cognac"; inferior kinds as "eau-de-vie." Under the Food and Drugs Act, 1879, it is a good defence to prove that the admixture of water has not reduced the spirit more than 25 degrees under proof. This corresponds to about 43 per cent. by volume of absolute alcohol. The addition of water and burnt sugar (for colouring) is the general method of adulterating brandy.

Branly's Coherer (*Elect.*) *See* WIRELESS TELEGRAPHY.

Brasque (*Met.*) A carbonaceous mixture containing coal-dust, tar, etc., used for lining certain furnaces.

Brass. An alloy of from 63 to 72 parts of copper with 27 to 34 parts of zinc. It is of a yellow colour, hard, but so ductile that it can be drawn out into fine wire, though, when intended for converting into wire, it is often alloyed with small quantities of tin and lead. The manufacture of brass was only introduced into England in 1639, when works were established at Esher in Surrey. Brass is both tougher and more fusible than copper, and does not tarnish so quickly. The best brass is made by cementation of calamine or oxide of zinc with granulated copper. The name "brass" sometimes includes GUNMETAL (*q.v.*) Brass is used for many parts of machinery—*e.g.* where small and somewhat intricate castings are required, or a certain degree of finish for the sake of appearance, or especially as bearings for moving parts of iron or steel, such as shafts (*see* BRASSES). In the construction of electrical apparatus and all kinds of physical instruments, brass plays a very prominent part, and it is used even on very large electrical machinery, as distinguished from electrical apparatus, when a non-magnetic metal is required, as in the case of a "spider"—the structure which connects the core discs with the shaft of an armature.

Brassard, Brassart (*Armour*). The armour which protected the arm, made of metal or leather (*cuir bouilli*).

Brass Bobbins (*Lace Manufac.*) Thin discs of brass that collectively contain one entire system of threads.

Brasses (*Eng.*) The blocks which form the actual bearing surface for a shaft; they are castings fitted into the "plummer block," and are accurately bored to fit the shaft.

—— (*Lace Manufac.*) Thin strips of brass, slightly attenuated or thinned down in the centre, which, when placed together, form sleys or guides that facilitate the working of the steel bars, appliances used in warping.

Brasses, Monumental. From earliest times and in all parts of the world it has been the custom of nations to erect some external sign which should point out the resting-place of their dead; these memorials necessarily assumed various forms. Upon some of them huge sums of money have been lavished, taxing to the utmost the skill of the sculptor, the architect, and the artist; in other cases a simple mound marks the burying place. The ancient Egyptians embalmed their dead, and thus preserved the very bodies of their friends and relatives. In other countries there was still the same strong desire; but instead of trying to preserve

the dead body, a more or less exact representation of the deceased was made in different ways, and these may be conveniently divided into three classes: (1) sculptured effigies; (2) representations engraven or incised on flat plates of brass or slabs of stone; (3) effigies painted on the flat (including glass windows). Though these three classes differ so much in the material used and in the manner of utilising it, yet they one and all have the same general design—*viz.* that of preserving not only the memory, but also the likeness and actual appearance of the deceased. The first of the classes was the most expensive, and consequently confined to persons of rank and wealth. Rarely do we find priests below the rank of abbot commemorated thus, and rarely the ordinary civilian, especially after the introduction of monumental brasses. A monumental brass, also termed "sepulchral brass," and often simply "brass," consists of a flat plate or plates of brass, originally of the mixed metal called *latten*, inlaid on large slabs of stone and representing in their outline, or by lines engraven on them, the figure of the deceased. In some instances, in place of the effigy, a cross was used, and neither name nor escutcheon, nor verse nor encomium is to be found. These memorials were sometimes placed on altar tombs, but more commonly they are to be found on the slabs which form part of the pavement of a church; and it is not improbable that this is another reason why these memorials were so generally adopted, because the area of the church, and especially that of the choir, was not thereby encumbered, as would be the case if sculptured effigies had been used. These brasses vary greatly as regards both size and cost. In Durham Cathedral lies the matrix of a brass to Bishop Beaumont (1333), which measures 16 ft. by 9 ft.; whilst at Cheam, Surrey, the effigy of John Yerde (1449) is only 6¾ in. high. Originally these plates were made in and imported from Germany and the Low Countries. In the early authorities it is termed *Cullen plate*, from which it may be inferred that Cologne (Köln) was the chief emporium. The manufacture of brass was only introduced into England in 1639, when two Germans established works at Esher, Surrey. The Rev. W. E. Hadow thus tersely sums up the advantage of studying these brasses: "Monumental brasses are extremely valuable. The herald, the genealogist, the chronologist, the architect, the artist, the palæographer, and the general antiquary will each and all find much to interest and instruct them in the several branches of knowledge, and they furnish us not only with well-defined ideas of celebrated persons, but make us acquainted with the manners of the times; while to history they give a body and a substance by placing before us those things which language with all its power is deficient in describing." Brasses were first used in England early in the thirteenth century, though the earliest now remaining is at Stoke d'Abernon, Surrey (1277). On the Continent is one at Verden, dated 1231. The brasses graven before the fifteenth century are the best examples of the art. Subsequently the art deteriorated till the eighteenth century, when the use of brasses ceased. Now the art has been revived with good success. The majority of the brasses in England are to be found in the counties situate nearest the Netherlands, and in the counties which were commercially connected with the Low Countries—*e.g.* Gloucestershire. Macklin's *Monumental Brasses* is a very useful handbook. For example of a "brass," *see* ARMOUR.

Brass Finishing. The turning and fitting of small brasswork, such as taps and valves. Usually a special trade distinct from the work of fitters and turners.

Brass Furnace. A small furnace, heated by coke, used in the brass foundry; the metal is usually placed in a crucible, and no blast is used.

Brassica. A genus of plants of the order *Cruciferæ*, including many plants of economic value. *B. nigra* is the black mustard; *B. alba*, the white mustard; *B. oleracea*, the cabbage, with its varieties, cauliflower, broccoli, etc.; *B. campestris*, the turnip; *B. napus*, the rape: yields colza oil.

Brass Moulders. A special class of moulders who rarely work in iron, and generally receive higher wages than iron moulders.

Brass Tube. (1) Common tube is brazed or soldered up from sheet brass; (2) solid drawn (*q.v.*) tubes are used for the most important work—*e.g.* surface condenser tubes.

Brass Winding (*Lace Manufac.*) A term used for brevity, and signifying the process of winding brass bobbins—sixty, eighty, or a hundred at once.

Brattice (*Mining*). A partition (wood or canvas) for separating two air streams in a level.

Brattishing (*Architect.*) Ornamental cresting. *See* CRESTING *and* TUDOR FLOWER.

Braunite (*Min.*) A sesqui-oxide of manganese, Mn_2O_3, brown to black; tetragonal. Ilmenau, in Thuringia, Iblefeld, Piedmont, Elba, etc.

Bravura, Con Bravura (*Music*). With power and brilliancy.

Brayer (*Typog.*) A wooden implement used to rub down and temper printer's ink.

Brazier. A portable fireplace with open bars, commonly used in different forms from times of antiquity.

Brazil Nut. *Bertholletia excelsa* (order, *Lecythidaceæ*). A large South American tree bearing round, hard fruits, containing eighteen to twenty-four seeds—the so-called Brazil nuts of the shops.

Brazilwood. *See* DYES AND DYEING.

Brazing (*Eng.*) The joining of surfaces by means of fused brass or spelter, applied to iron, steel, brass, and other metals, and much stronger than soldering, besides being applicable in many more cases. The joints are cleaned and covered with borax; some of the alloy is then placed over the joint, and heated until it runs in, when it is allowed to set, and any superfluous metal cleaned off. Joints in cycle frames are always brazed, and so neat and strong is a good brazed joint that a broken band saw can be mended by this method without the production of any roughness or projection which would interfere with the action of the saw.

Bread (*Foods*). Bread consists of two classes, the fermented and the unfermented. In the former yeast is used, and in the latter chemical means are adopted for aërating the bread. It should be well baked, not acid, not bitter, and of a good colour. Bread is rich in proteids and starch, but poor in salts and fats. Rice, potatoes, beans, peas, barley, and alum are the usual adulterants. The following gives the methods of manufacture and the chemical results: Flour is mixed with water to form a dough. In this operation gluten, a mixture of nitrogenous substances, is produced. The dough is impregnated with carbon dioxide, either by forcing into it carbon dioxide under pressure (Dr. Dauglish's

system) or by adding yeast. The yeast converts the starch of the flour into maltose and dextrine, and then the maltose into alcohol and carbon dioxide. This gas, hindered from escaping by the gluten, makes the bread lighter. The fermentation and subsequent baking cause several chemical changes in the mixture—*e.g.* the starch is partly changed to more soluble sugars, and it can no longer be separated from the nitrogenous compounds; also, the nature of the nitrogenous matter is changed in some way. Carbon dioxide and alcohol are in part expelled in baking. White bread contains from 7 to 10 parts of proteid, 55 of carbohydrates (starch and sugars), 1 of fat, 2 of salts, and the rest up to 100 parts water. There is on an average in new bread ·3 per cent. of alcohol. Alum, which is often present as an adulterant in bread, serves to whiten it. Experiment has shown that small quantities of alum are not injurious to health. BROWN OR WHOLEMEAL BREAD is made from undressed wheat, and contains the bran as well as the flour. It was formerly considered to be more nutritious than bread made from the finer flour, inasmuch as the bran contains more nitrogenous matter. But it has been pointed out that the nitrogen of cereals exists in two forms—the coagulable and the non-coagulable albuminoids—the former being nutritious, the latter consisting of alkaloids and other compounds containing nitrogen. Bran contains the latter, which is comparatively useless, whereas in fine flour the nitrogen is found in the first condition. An argument against the use of brown bread is that the cellulose in the bran acts as an irritant, stimulating peristaltic movement (*q.v.*) The excess of cellulose also cannot be digested, and is said to interfere with the absorption of digestible foods. *See* BAKEHOUSES.

Breadth (*Lace Manufac.*) Any width of lace less than a "web" that is complete in itself.

—— (*Paint.*) Is thus defined by Ruskin: "Good composers are always associating their colours in great groups . . . and securing . . . what they call 'breadth'—*i.e.* a large gathering of each kind of thing into one place, light being gathered to light, darkness to darkness, and colour to colour."

Breakdown Crane (*Eng.*) An accident crane. *See* CRANES.

Breaker. A machine used in paper manufacture for disintegrating rags into "half stuff."

Breaking (*Foundry*). A striated appearance on the surface of melted iron; the quality of the iron can be judged to a certain extent by the appearance of these striations.

Breaking Joints (*Build., etc.*) The prevention of two or more successive joints from coming into line. This is done to increase the strength of the structure. The BOND (*q.v.*) in masonry is an example; the arrangement of the joints of piston rings (*q.v.*) is another.

Breaking Pieces (*Eng.*) Short shafts by which power is transmitted to the rolls of a rolling mill. They are made weaker than the axles of the rolls, so that if the mill is overstrained they will break first, and prevent a fracture of the rolls or their axles.

Breaking Strength. The force or load necessary to break a piece of material of specified size.

Break Lathe (*Eng.*) A large lathe whose bed can be disconnected from the head stock so that it can be moved farther away, to suit larger work.

Breaks in the Succession of Strata (*Geol.*) These mean nearly the same thing as "unconformity"; but it is sometimes convenient to employ the present expression in cases where rocks are absent which are known to occur elsewhere, but where there is no visible discordance between the two rocks which succeed each other in the same section. A further distinction is made in the case of any marked hiatus between the organic remains of two apparently conformable sets of rocks, in which case the term PALÆONTOLOGICAL BREAK is used.

Breakwater (*Marine Eng.*) A bank or wall of masonry used to protect a harbour, etc.

Breast (*Build.*) The part of a wall projecting into a room and containing the flues.

—— (*Mining*). The face or working surface in a level.

Breast Beam (*Cotton Weaving*). The front cross-rail of loom over which the cloth passes to the cloth roller.

Breast Hole (*Met.*) In a cupola, the door or opening just above the base for lighting the fire and extracting the cinders and slag.

Breastplate (*Arm., etc.*) Armour which protected the breast. A large metal ornament worn on the breast.

Breast Wheel (*Eng.*) A water wheel which turns in a quadrant-shaped bed, so that the water strikes the floats at the level of the axle, and remains in contact with them till the lowest point of the wheel is nearly reached.

Breccia (*Geol.*) A compacted aggregate of fragments of stone which are angular instead of being rounded, as they are in a conglomerate. The angularity of the constituents serves to indicate that the stones have not been exposed to the rounding action to which running water gives rise, and the feature in question may thus become one of some importance in relation to the history of the rocks of which a breccia forms a part.

Breeches Pipe (*Eng.*) A ⅄-shaped pipe in a locomotive which receives the steam from the two cylinders and discharges it into the chimney, in order to force the draught.

Breeze. A name given to various kinds of fuel in a fine state of division. Thus coke breeze is finely divided coke. In brickmaking, sifted coal cinders are extensively used, both for mixing with the loam before moulding into bricks and for putting between the layers in a clamp when the bricks are burnt in that way.

—— (*Build.*) Fine cinders used with cement to make concrete.

Breguet Spring (*Watchmaking*). A flat spiral balance spring with its outer coil bent up into a horizontal plane parallel with the body of the spring, and then curved in towards the centre and fixed to the stud between the outer coil and axis of balance. This spring, which is only found in better class watches, secures less variation in timekeeping when the position of a watch is altered by the movement of the wearer or otherwise.

Bressummer (*Build.*) A beam carrying a wall, as a girder over a shop front.

Bretessé (*Her.*) An ordinary with edges embattled; also called CRENELLÉ.

Breve (*Music*). *See* NOTE.

Brevier (*Typog.*) Type one size smaller than bourgeois and one size larger than minion. *See* TYPE.

Briar Root. *See* WOODS.

Bric-a-Brac. Antique curiosities of artistic character: furniture, china, plate, fans, statuettes, etc.

Brick Arch (*Eng.*) In locomotives, an arch of firebrick placed in front of the openings of the tubes to deflect the flame backward.

Brick Earth (*Geol.*) Any loam or native mixture of clay with sand which serves for the manufacture of bricks. In the south-east of England, and especially in the Thames Valley, it is usually restricted to a kind of buff or ochreous loam which has been left as a sedimentary deposit on the sides of the valley. By many it is regarded as a form of alluvium; others think it represents a deposit formed at a time when the river was ponded back into a lake by an ice barrier across its mouth at the climax of the Age of Snow.

Bricking Up (*Foundry*). In moulding, the formation of part of a large mould with bricks instead of using sand alone.

Bricknogged (*Build.*) A brick partition with horizontal NOGGING PIECES (*q.v.*) to tie it together.

Bricknogged Partition (*Build.*) A partition built of bricks and mortar. with nogging pieces (*q.v.*) about every 3 ft. of its height to bond it together.

Bricks (*Brick Earths*). The clay from which bricks are formed varies considerably in composition. The following are examples: *Reddish-Brown Clay:* Silica, 53; alumina, 31; water, etc., 9; iron oxide and lime, 3·5; magnesia, 2·5. *Red Brick Clay:* Silica, 50; alumina, 24; water, etc., 22; iron and lime, 2·7; magnesia, 1·3. *A Common Marl Clay:* Silica, 33; alumina, 11; water, etc., 10; lime, etc., 40; magnesia, 6. *A Sandy Clay:* Silica, 60; alumina, 24; water, 12; lime, etc., 2·4; magnesia, 1·6. It will be instructive to compare these with the analysis of very pure clay, such as china clay: Silica, 45; alumina, 45; water, 8; iron oxide and lime, 2. The commonest bricks are made from a marly or a sandy clay, the latter being often termed "loam." An artificial imitation of marl, termed "malm," is produced by mixing clay and chalk with water in a puddling mill.—MANUFACTURE: The first operation is the removal of the surface earth, which is termed "unsoiling." The clay is then cut out, broken into small pieces by the spade, and exposed for a considerable time to the air, in order to become "weathered." It is then cleared of stones, either by hand picking or, on a larger scale, by washing in a mill, from which the clay, mixed with water to a creamy consistency, is allowed to flow into a WASH BACK, where it is left to dry in the air until it attains the requisite consistency. It is then cut out in blocks, ground with breeze in the PUG MILL, and then is moulded into the shape of bricks by hand labour or by a brick-making machine. The next process is extremely important: it consists of drying the bricks in air. They are stacked in long rows on raised platforms of earth known as HACKS, and are arranged in such a manner as to leave numerous air spaces between them. They are protected from the rain by a loose roof of straw, or sometimes by light screens made of reeds, or else by a simple form of roof, and are left until the whole of the visible moisture has evaporated. The bricks are then termed "green bricks." When sufficiently dried, the green bricks are ready to be burned. There are two principal ways of carrying out this operation. In the older method, the bricks themselves are built up into a kind of hollow chamber, with flues running through it, termed a CLAMP. A fire is kept burning inside this until the whole of the bricks have been sufficiently burned. Those close to the flues are in most cases seriously overburnt, and are termed "burrs." Those which are less overburnt are termed "hard stock," and are useful for many building purposes. The outermost bricks of the clamp are frequently left underburnt, and are useless for all ordinary work. A more modern process is to use a permanent kiln for burning; and in this case it is much easier to attain uniformity in the process, and also to regulate the burning to any desired degree.—VARIETIES OF BRICKS: (1) *Cutters or Rubbers:* A fine-grained brick, commonly red, which is suitable for working to any definite shape, for arches, mouldings, etc. Malm bricks are often used for the purpose; and two of the best varieties of cutters are Fareham reds—a deep red brick made from the Fareham clay; and Lawrence's cutters, made from a brick earth at Bracknell, which is carefully strained and washed. (2) *Dutch Bricks:* A light-coloured hard brick suitable for paving and similar work. (3) *Gault Bricks* or "*Gaults*": Bricks made from the blue clay termed by geologists "gault"; frequently made with holes to serve as air bricks or ventilating bricks. (4) *Leicester Reds:* A heavy brick which has been subject to pressure in its formation. (5) *Malm Builders:* Kiln-burnt bricks, from specially prepared malm. (6) *Red Builders:* Used for good building work; made from washed earth. (7) *Rubbers:* Another name for cutters (*q.v.*) (8) *Shippers:* The last selected stock or ordinary bricks, so called from being originally those which were selected for shipment. (9) *Stafford Blues:* Very heavy hard brick, containing a high percentage of iron (10 per cent.), and extremely durable. (10) *Stocks:* Also termed "grey stocks," or London stocks, a general name for the ordinary clamp-burnt bricks of the better kind. (11) *Suffolks:* Cream-coloured bricks made from marl; used for facework. In addition to the above, moulded bricks are used for arches, quoins, plinths, string courses, and other ornamental work. Those used for arches are often called "arch bricks" and "gauged bricks." Other bricks are finished with a polished surface, sometimes by ordinary glazing with salt, and at others by a more elaborate glaze similar to that used for earthenware. These are used for ornamental work, for reflecting light, or for sanitary purposes. —FIREBRICKS: Firebricks are used for the interiors of flues and furnaces. They must be infusible at the temperature to which they will be exposed; they must also be free from cracking at this temperature, and must retain their shape and size, as any alteration in this point would probably destroy the whole interior of the furnace, causing the roof and arches to give way. In other cases, firebricks have to resist the destructive action of the fluid metals and slags produced in the furnace. The requirements of a good firebrick, therefore, vary considerably, but in nearly all cases are exacting and difficult to meet. Only special clays, termed "fireclays," can be used. An example of fireclay is as follows:—Silica, 50; alumina, 30; water, etc., 12; iron oxide, 4; lime, 2; magnesia, 2. The chief points in which this differs from an ordinary brick earth are the comparatively high per-

centages of alumina and iron oxide and the absence of any free alkalis. These characteristics contribute very largely to the infusible character of the brick. The presence of alumina in large quantities is not, however, essential in all cases, as a very good form of firebrick is made from Kieselguhr, which is a highly silicious earth, originally produced by minute organisms called "diatoms." The composition of Kieselguhr is typically: Silica, 84; alumina, 1; water, 7; iron oxide, 2; lime, ·8; magnesia, ·7; organic matter, 4·5. In burning these Kieselguhr bricks the iron appears to act as a flux—*i.e.* helps to form a fluid substance, which, when it solidifies, cements the remaining material together. These bricks are very light, but very durable, and are much used for firebricks in chemical works.

Bridge (*Eng.*) (1) An arch or series of arches of brick, stone, or cast iron; (2) a platform carried on wrought iron or steel girders, either supported on piers of masonry or metal, or hung by chains from lofty piers at each extremity of the bridge; (3) applied to various parts of mechanism or structures which have some resemblance to an ordinary bridge; (4) a barrier placed across a furnace to deflect the flames and hot gases. *See also* ARCH.

—— (*Music*). The piece of wood on which the strings of musical instruments are stretched.

Bridge, Wheatstone (*Elect.*) *See* WHEATSTONE'S BRIDGE.

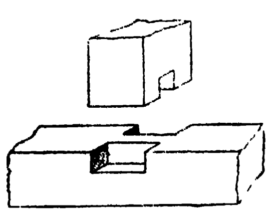
Bridging Joist (*Carp.*) The timbers to which the floor boards are nailed.

Bridle (*Eng.*) The loop by which a slide valve is connected to the valve rod.

—— (*Dec.*) The method of tying up a painter's brush when it is new and the bristles are too long for use. Whipcord is wound around the bristles from the binding, and is secured by being tied to the handle or to pieces of copper wire bound in with the bristles for the purpose. Various ready made bridles are also used.

Bridle Butts *or* **Backs** (*Leather Manufac.*) Butts (*q.v.*) tanned for bridle and harness work; must be pliable, free from blemish, and of good colour.

Bridle Joint (*Carp.*) A joint of the form shown. Used in place of a mortice and tenon.



BRIDLE JOINT.

Brigandine Armour. Armour consisting of canvas or leather, quilted with small thin pieces of iron; worn by mediæval archers and crossbowmen.

Bright Red Heat. A temperature ranging from 1700° to 1800° F.

Bright Work. Surfaces which have been machined or merely polished by the file, emery, etc.

Brill (*Zool.*) *Rhombus lævis* (family, *Pleuronectidæ*). A flat-fish allied to the turbot, but inferior to the turbot as food.

Brillante (*Music*). Brilliant.

Brilliant (*Min.*) A term used for a special form of cut diamond. *See* DIAMOND *and* PRECIOUS STONES.

—— (*Typog.*) Type a size smaller than diamond, and practically the smallest used. *See* TYPE.

Brimstone. A common name for artificially prepared sulphur. *See* SULPHUR.

Brinded *or* **Brindled** (*Her.*) Said of animals covered with spots or streaks of colour.

Brine Pump (*Eng.*) *See* SALTING.

Brin's Process. A method of obtaining oxygen from the air on a large scale. Air is freed from moisture and carbon dioxide, and passed under a pressure of about two atmospheres over barium monoxide, BaO, heated to a constant temperature of 700°. Under these conditions BARIUM DIOXIDE, BaO_2, is formed. The residual nitrogen is allowed to escape; then the pressure is reduced to a few inches of mercury, and the dioxide gives up oxygen, which is collected; the monoxide remains, and is used again.

Brio (*Paint.*) Painted with spirit or "go."

Bristled (*Her.*) When the bristles of a boar are of a different tincture from the body.

Bristles. The coarse stiff hairs obtained from the pig and used in brushmaking. They are imported chiefly from Russia.

Bristol Board. A fine kind of pasteboard or cardboard with a smooth or glazed surface; used for pen-and-ink drawings, watercolour drawings, and mounts.

Bristol Porcelain. Pottery of the nature of Delft was made in Bristol as early as the close of the seventeenth century. A manufactory of porcelain was established in 1768 by Champion, who in 1774 took over Cookworthy's patent for the manufacture of hard-paste. There is no record of this porcelain having been made after 1777. Two other manufactories were established for the manufacture of earthenware, one of which (Pountney's) is still in existence. For Porcelain Marks, *see under* POTTERY.

Britannia Metal. A white alloy of tin and antimony, usually also containing small amounts of copper and zinc; a typical specimen contained: Tin, 86; antimony, 10; copper, 1; and zinc, 3 per cent.

Britch (*Woollen Manufac.*) The fibre from the extremity of the tail end of fleece.

British Gum. This is not a true gum. It is prepared by carefully heating starch, when a product containing dextrine or substances allied to it is obtained.

British School of Painting. *See* PAINTING, SCHOOLS OF.

Brittle Silver Ore (*Min.*) A synonym for STEPHANITE (*q.v.*)

Broach (*Architect.*) A spire, generally used to denote that kind of spire which rises from a tower without any parapet, as is usual in Early English architecture.

—— (*Eng.*) A tool for enlarging and finishing off round holes which have been drilled or punched.

—— (*Woollen Manufac.*) A wooden spindle on which the cops of yarn are fixed for warping, etc.

Broadcloth (*Woollen Manufac.*) Fine, plain-wove black cloth, dressed. Used principally for men's clothing.

Broad Gauge (*Eng.*) Railway lines set 7 ft. apart; now abandoned. *See* NARROW GAUGE.

Broadside. A sheet of paper printed on one side only, the matter generally being of a popular character.

Brob (*Eng., etc.*) A large spike used to fix heavy timber work.

Brocade (*Cotton Weaving*). A class of figured weaving produced by means of the "Jacquard," in which the warp and weft are made to float indiscriminately on the surface of cloth to form a desired pattern or figure, the ground weave being of a firm structure. The figures are principally weft.

—— (*Silk Manufac.*) A term now applied to most figured silken fabrics; originally it was used to denote only those silks where the figure consisted of various-coloured wefts and metal threads woven into the cloth by means of small shuttles, which were passed under the warp threads in such places as the figure occurred, instead of being thrown across the entire width of the work.

Brocatel *or* **Brocatello.** A variegated species of marble, obtained principally from different parts of Italy.

Brocatelle (*Silk Manufac.*) A thick figured silk used for upholstery purposes, made with an extra weft of linen yarn, which causes the satin figure to have a raised or plump appearance.

Broché. Fabric enriched with figures or design in relief.

Broken Entablature (*Architect.*) An entablature which does not project uniformly from the face of the wall, but has an increased projection over each column or pilaster. *See also* ENTABLATURE.

Broken Glass (*Met.*) Used to cover the surface of molten brass to check oxidation.

Broken Over (*Bind.*) Used in respect of plates when a fold has been made a short distance from their back edge before they are fixed in a volume.

Brokes (*Woollen Manufac.*) Short locks of wool removed from the edges of the fleece, grown on the neck and belly.

Bromates. Salts of bromic acid. POTASSIUM BROMATE, $KBrO_3$, is made by adding bromine to caustic potash: $6KOH + 3Br_2 = 5KBr + KBrO_3 + 3H_2O$. The bromate, being much less soluble than the bromide, is separated by crystallisation. Bromates on heating decompose, giving oxygen and a bromide.

Bromic Acid, $HBrO_3$. Forms a strongly acid liquid; it is a powerful oxidising agent; hence it bleaches. It may be obtained by passing chlorine into bromine water or by acting upon silver bromate (prepared by adding silver nitrate to potassium bromate) with water and bromine.

Bromide Emulsion (*Photo.*) A solution of gelatine containing silver nitrate and potassium iodide and bromide. A good formula is: Gelatine, 280; $AgNO_3$, 175; KBr, 135; KI, 5 parts by weight.

Bromide Prints. Prints on paper, porcelain, etc., which has been coated with a gelatine emulsion containing silver bromide, very similar to that used on dry plates. The prints are developed and fixed like dry plates.

Bromides. Salts of hydrobromic acid (HBr). *See also under* POTASSIUM *and* SILVER.

Bromine, Br. Atomic weight, 80. A dark red heavy liquid (sp. gr. 3), boiling at 59°; it has a powerful and irritating smell, and the vapour attacks the eyes. Unites directly with many elements to form bromides (union with potassium and phosphorus is explosive). Soluble in carbon disulphide and in acetic acid; also sparingly soluble in water, the solution decomposing in light. Acts on many organic compounds, forming either substitution products—*e.g.* C_6H_6 (benzene) gives C_6H_5Br (monobrombenzene) or addition products—*e.g.* C_2H_4 (ethylene) gives $C_2H_4Br_2$ (ethylene dibromide). Prepared on large scale by heating the mother liquor obtained in the preparation of potassium chloride from Carnallite by means of steam, and passing chlorine into it. The chlorine liberates bromine from the magnesium bromide, and the escaping bromine is condensed. On small scale it is produced when a bromide is distilled with manganese dioxide and sulphuric acid. Resembles chlorine in its chemical behaviour; thus it bleaches, and acts upon alkalis like chlorine (*q.v.*)

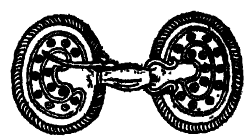
Bromo Compounds. These are formed from organic compounds by replacement of one or more hydrogen atoms, directly or indirectly, by one or more bromine atoms. Thus tribromophenol is phenol (C_6H_5OH), in which three hydrogen atoms have been replaced by three bromine atoms, giving $C_6H_2Br_3OH$, in which the bromine atoms occupy the positions 2:4:6 in the benzene ring (*see* BENZENE), the OH group being in position 1.

Bronchi (*Zool.*) The two tubes formed by the division of the trachea or windpipe. They again divide, and their branches pass into the lungs, where they ramify.

Bronze. An alloy of copper, tin, and zinc in somewhat variable proportions. The British coinage is composed of 95 parts of copper, 4 of tin, and 1 of zinc. Ancient bronzes contain only copper and tin. *See also* GUNMETAL.

Bronze Age (*Geol.*) The prehistoric period when men employed instruments of bronze in war, in the chase, and largely for domestic purposes. It followed the Neolithic Age, when smoothed stone instruments were used, and it preceded the period when iron began to come into general use. Both its commencement and its termination are indefinite, and they varied in different countries according to local circumstances.

Brooch (*Cost.*) An ornament or clasp to which a pin is attached, now used chiefly for fastening some portion of female wearing apparel, generally on the breast, but formerly often worn by men also, frequently on the hat or cap.



It is still one of the indispensable ornaments of a Highland costume. The illustration is from a Danish brooch of the later Bronze age.

Brookite (*Min.*) TITANIC OXIDE, TiO_2. Rhombic. It often occurs in brown capillary crystals. Two of the chief localities are Cornwall and Dauphiny.

Brought Forward (*Dec.*) This term signifies that all work to be painted is ready for the finishing coat at the same time.

Brown (*Paint.*) A composite colour produced by mixing orange and black, or red, black, and yellow. Great variation in shade can be obtained according to the proportion of the constituents.

Brown Bear (*Zool.*) *Ursus arctos* (family, *Ursidæ*). The Brown Bear is valued for the sake of its fur and flesh (hams and paws) and fat.

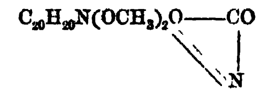
Brown, Bismarck. *See* DYES AND DYEING.

Brown Coal (*Geol.*) A stratified deposit of fossil matter of vegetable origin which has undergone a

certain amount of change within the strata enclosing it, but which change has not proceeded sufficiently far to convert the substance into true coal. The percentage of carbon present is usually between 65 and 80, and of oxygen between 25 and 15. It is often associated with strata of fresh water origin. It is an important source of fuel in connection with some of the Tertiary rocks of the Continent. *See also* COAL.

Brown Hæmatite (*Min.*) A synonym for Limonite (*q.v.*)

Brucine.



An alkaloid occurring along with strychnine in nux vomica. Forms colourless prismatic crystals or pearly flakes; melts at 178°. Physiological action similar to strychnine, but 38½ times less powerful. It is more soluble in water and in alcohol than strychnine. It is lævorotatory; a tertiary base; and although it contains two nitrogen atoms, it is a monacid base. With nitric acid it gives a red colour even in very dilute solutions; the colour changes to violet on adding stannous chloride. This forms a very delicate test either for brucine or nitric acid.

Brucite (*Min.*) Native magnesium hydrate; it occurs in tabular hexagonal prisms with a perfect basal cleavage. Thin laminæ are flexible, but not elastic. Composition: $M_g(OH)_2$, magnesia = 68·97, water = 31·03 per cent. When heated before the blowpipe it does not fuse, but becomes brilliantly incandescent. It occurs at Swinna Ness in the Shetland Isles, and at several localities in the United States.

Brunswick Black. A quick-drying black varnish made from asphaltum and used principally for coating iron.

Brunswick Green (*Paint.*) A pigment used in oil painting, manufactured from carbonate of copper and chalk or lime. In trade work, a useful series of greens is made, in four or five shades, from chrome yellow and Prussian blue, on a base of barytes. They are apt to fade, but may safely be mixed with other pigments excepting those which contain sulphur. Brunswick greens are inferior in quality to chrome green.

Brushes (*Dec.*) *See* PAINTER'S BRUSHES.

—— (*Elect. Eng.*) Strips of copper, either solid or built up of gauze, or else rods of carbon, which convey the current from the terminals of an electric motor to the commutator or in the reverse direction in the case of a dynamo. By means of "rocking frames" or holders the brushes can be moved round the commutator until the best position (that where least sparking occurs) is obtained. This adjustment has to be made with great care, or loss of energy and injury to the machine will result.

Brush Holder (*Elect. Eng.*) The support or frame carrying the copper (or carbon) strips by which the current enters or leaves a motor or dynamo. The brush holders are carried by a "rocking frame" which enables the point of contact of the brushes with the commutator to be varied at will.

Brushwork (*Paint.*) (1) A term used by artists to signify the manner in which the pigments are laid upon canvas in oil painting and upon paper in water-colour work. Every painter has his particular method of handling his materials, and the quality of his brushwork is one of the most important factors in the expression of his individuality. (2) A method of teaching drawing and design by means of water-colour drawing, chiefly in vogue in elementary schools. The painting is executed by means of the brush alone, no outline of the subject being previously made.

Brussels Lace, *also called* **Point d'Angleterre.** Perhaps the most representative of all laces either for quality or beauty of design, which changes with the fashion and always keeps up to date. It was first made in the fifteenth century, and about 1626 the city of Brussels had attained such proficiency in the manufacture as to be the envy of the whole of the surrounding districts. England also becoming alarmed at the enormous sums paid to the foreigner, introduced certain fiscal changes, with the idea of stopping its importation and at the same time fostering the English lace industry. The merchants brought skilled lacemakers to this country, and attempted to introduce the manufacture; but as the British workmen had not attained proficiency in the production of the thread, the result was failure. The name was then changed to Point d'Angleterre, and smuggling was resorted to, which seems to have been quite a success. Nearly every known stitch or method may be embodied in Brussels lace, as the principle of manufacture lends itself to distinctive treatment, and the various objects and fillings and different varieties of ground are made separately, each by the worker most skilled in her particular department, and afterwards combined.

W. H.

Bubble Tube. The glass tube of a level containing spirit. It encloses a bubble of air.

Bucentaur. A mythical creation half man, half ox. Also the name of the State barge or galley of Venice in which the Doge and Senate performed the ceremony of wedding the Adriatic.

Bucket (*Eng.*) (1) The scoop used with various forms of dredgers; (2) The piston of a suction pump; (3) The receptacle which catches the water in water wheels.

Bucket Ladder Dredger (*Civil Eng.*) A continuous chain driven by machinery carries a number of sharp-edged buckets, which scoop up the material and raise it above water level, where it is discharged into suitable barges. The chain works over wheels at the top and bottom of a frame in such manner that the buckets at the lowest part of the chain touch the bottom of the channel.

Bucket Valve (*Eng.*) The valve in the piston of a common suction pump.

Buckle (*Architect.*) *See* MASK.

—— (*Cost.*) An instrument, often ornate, consisting of a rim of metal with a chape and tongue. Used for fastening straps or belts.

—— (*Eng.*) The curving of a flat plate caused by stresses set up from contraction and other causes: a permanent "set" or twist in a piece of material which should be flat.

Buckled Plates (*Eng.*) Plates to which a dish-like curve has been given; used in some forms of bridge construction, as the plate has greater stiffness than a flat one.

Buckram. A strong coarse form of linen material of plain texture, highly finished. Used for linings and for binding books likely to be much handled.

Buckskin (*Woollen Manufac.*) Fine twilled woollen cloth, with the weave or twill lines clearly defined.

Buckskin Leather. Originally made from buckskins, dressed by oil dressing; now made from any kind of deer. Frequently made from sheep, calf, and horse hides.

Buckwheat. *Fagopyrum esculentum* (order, *Polygonaceæ*). The fruits of this member of the dock family constitute a much used food in some European countries and in America.

Buddle (*Mining*). A machine for washing ore by rotating it in a circular vessel or pool of water.

Buff (*Colour*). A light yellow.

—— (*Eng., etc.*) A wheel covered with leather, on which fine emery, etc., is placed for polishing metallic objects.

Buff Coat. A military outer garment made of skin or other thick and elastic material. The sleeves were short, and the garment was laced across the chest. Worn by soldiers during the seventeenth century.

Buffer (*Eng.*) A stop intended to check a heavy shock by causing the gradual compression of a spring or its equivalent.

Buffing (*Leather Manufac.*) A process by which the grain surface of the leather is removed: formerly done by hand with a buffing knife; now largely done by machine.

Buff Leather. Leather from which the upper surface or "grain" has been "buffed" off (removed). Chiefly used for Army work. Dressed with oil.

Bugle. *See* MUSICAL INSTRUMENTS: WIND, BRASS.

Bugle Horn (*Her.*) A small hunting horn. When blazoned, it should state if the shoulder strap is shown; if so, the bugle is *enguiché*.

Buhl (*Furn.*) A kind of furniture manufactured by Boule (1642—1732), an Italian wood carver, who introduced this style in France during the reign of Louis XIV. Unburnished gold, brass, mother of pearl, tortoiseshell, etc., worked in complicated patterns were used for inlaying. Buhl is a German form of the name.

Building Motion (*Cotton Spinning*). For building up the layers of roving on the bobbins of a fly frame so as to lay them uniformly, and also give a tapered shape at the top and bottom; sometimes termed "box of tricks." Occasionally used in respect of the building of a cop on a mule.

Building Stones. The qualities requisite in stones suitable for building work are very various, and depend on the nature of the work. Strength and durability are usually the two most important qualities; but the exact nature of these will depend on whether the stone is to be exposed to the outer air or to be under water, or only to be used in the interior of the building. Ease of working depends upon the softness or hardness of the stone: a very hard stone might be extremely difficult to work, both in the quarry and on the bench; while a very soft one may break away under the tools, and therefore be useless. For ordinary building purposes limestone and sandstone in some form are the stones most used. The former is always liable to be attacked by the atmosphere to a considerable extent, as rain water, containing a certain amount of carbonic acid in solution, can dissolve away carbonate of lime, which is the chief constituent of a limestone. Sandstones, being composed largely of silica in a form of minute grains of quartz, are not liable to these destructive actions, and their durability will depend almost entirely on the strength of the natural cementing material by which the grains of quartz are held together in the stone. Granite and rocks of its class are the most durable of all stones; but they are difficult to work with ordinary mason's tools, and as they occur in huge masses in the earth, instead of being in layers or "stratified," as limestones and sandstones are, the expense of quarrying them is also very much greater. For these reasons granite and similar rocks are only used in the very heaviest work where enormous strength is absolutely necessary, or else in decorative work where the high cost is not an obstacle. Marbles and similar rocks are as a rule only suited for internal work where they will not be subject to much wear and tear. The classification of building stones is a somewhat difficult matter. The geologist would classify them according to the manner in which they have been formed, dividing them into three classes—the aqueous rocks, which have been formed by the action of water—*e.g.* limestones and sandstones; the igneous rocks, which have solidified from a fluid condition, and include granite, syenite, basalt, and similar rocks; and metamorphic rocks, which are rocks originally belonging to either of the above classes, afterwards modified by the action of heat or intense pressure. For building purposes it is more convenient to classify all rocks in accordance with the uses to which they are put. This gives us the following classification of stones used in: I. ORDINARY MASONRY WORK: (**A**) Limestones. (**B**) Sandstones, and occasionally certain other rocks. II. HEAVY MASONRY AND ENGINEERING: Stones used in the foundations of heavy buildings, piers, breakwaters, and engineering work generally; various forms of granite, syenite, etc. III. PURELY ORNAMENTAL WORK: Marbles, serpentine, granites, syenites, etc. It will be seen that there is a certain amount of overlapping in the above classification, which it is impossible to avoid, as many of the stones which are most useful for the heaviest work are also extensively used for purely decorative purposes. I. (**A**) The principal limestones in actual use are as follows: (1) *Ancaster Stone* and "*Oolite*" *Limestone:* From Lincoln, used for general building work in the locality, and for doors, windows, etc., elsewhere. (2) *Bath Stone*, "*Great Oolite*" *Limestone*. Found in the Somerset hills, at Box, Chippenham, Doulting, etc. This stone is soft when first quarried, but gradually hardens in air. It is slightly shelly, but fine grained; very extensively used for general building work, and also for external decorative work, as it is extremely suitable for cutting and moulding. Examples: Bath Abbey, Glastonbury Abbey (eleventh century), Wells Cathedral (twelfth and fifteenth centuries), and many collegiate buildings in Oxford from the Twelfth to Fifteenth centuries. All these buildings are in a good state of repair, putting the durability of the stone beyond dispute. (3) *Bolsover Stone*, "*Magnesian Limestone*," or "*Dolomite*": Composition (percentage): calcium carbonate, 51·1; magnesium carbonate, 40·2; iron and aluminium oxides, 1·8; silica, 3·6; water, etc., 3·3. Easily worked stone, not very durable. (4) *Caen Stone:* From the "Jurassic" rocks of Normandy. Very fine stone for decorative work, much used on the Continent and in many buildings in this country; not as durable as many other building stones. (5) *Doulting Stone:* A variety of Bath stone. (6) *Ham Hill Stone:* A variety of Bath stone. (7) *Headington*

Stone: A soft limestone from Oxfordshire. It has been used in the restoration of many Oxford buildings; but it is easily seen, on inspection, that the stone is not very durable, as the restored work shows many signs of decay. (8) *Huddlestone Stone:* A limestone quarried at Park Nook and other places in Yorkshire. (9) *Portland Stone:* A limestone from the upper Jurassic rocks of the Isle of Portland, near Weymouth. Superior to the oolitic limestones in hardness and durability, but less adapted to delicate chiselling. Colour, white to light brown; stands the weather well. This stone has been much used for many years. St. Paul's Cathedral is a fine example; also the Goldsmiths' Hall, and the Customs House, built 1817. Another good example which should be inspected by students of building materials is the fine statue, a copy of the "Farnese Hercules," in the Museum of Practical Geology. (10) *Mansfield Stone:* A durable arenaceous limestone of light colour, used in the lower parts and foundations of the Houses of Parliament; also extensively used for paving. (B) Sandstones used in general building. (1) *Belton Stone:* A sandstone from the "Lower Keuper" rocks of Shropshire; white and light red. (2) *Branley Stone:* Coarse-grained sandstone from the "Millstone Grit" of Yorkshire; very durable; suitable for general building, paving, stone steps, and also heavy work, such as foundations for machinery, piers, and bridges. (3) *Craigleith Stone:* A whitish-grey sandstone; very durable; used for general building, especially Ashlar work, steps, and landings. Much of the older part of the city of Edinburgh is built of this stone. Quarried at Craigleith, on the north-west side of the city. (4) *Darley Dale Stone:* From Derbyshire. A yellowish-brown sandstone of fine grain, containing flakes of mica. Darley Abbey and Birmingham Grammar School are built of this stone. (5) *Dumfries Sandstone:* A bright red sandstone, locally used, but not very durable. (6) *Dundee Sandstone (Arbroath Flags):* From the "Old Red Sandstone." Splits into large and flat "flags," and is much used for paving, as it is hard and durable and very impervious to moisture. (7) *Elland Sandstone:* From the Millstone Grit of Yorkshire. A fine greyish-brown micaceous stone, used for paving. (8) *Harrock Hill Sandstone:* A coarse-grained stone, used for paving, heavy foundations, engine bases, etc. (9) *Heddon Stone:* From the "Carboniferous Limestone Series," near Newcastle. A light brown stone, sometimes containing fine layers (or "laminæ") of black carbonaceous matter. Used locally and also elsewhere for the facings of buildings. Many examples of its use are found in Edinburgh. (10) *Hollington Stone:* A fine-grained sandstone, white to grey in colour, from Uttoxeter; used in many large buildings in the Midlands—*e.g.* Drayton Manor and Derby Town Hall. (11) *Kentish Rag:* A sandstone of calcareous nature (*i.e.* containing a certain amount of carbonate of lime), from the "Lower Greensand" group of rocks. A light brown or grey stone; fine, shelly, not very hard or durable; extensively used in many buildings of modern date in the south-east of England. Quarried at Godstone, Maidstone, Folkestone, etc. (12) *Longridge Stone:* from the "Yoredale Rocks" of Longridge Fell in Lancashire. A durable sandstone; used in the north of England—*e.g.* Preston Town Hall. (13) *Manley Stone:* A sandstone found in Cheshire; colour varies from white to red; used in the restoration of Chester Cathedral. (14) *Penistone Sandstone:* Yorkshire. Used for flagstones. (15) *Penrith Sandstone:* A bright red sandstone from the "Permian" rocks. In many ways a good building stone; used throughout the town of Penrith and neighbourhood, and sometimes elsewhere, on account of its fine colour and appearance. It is not, however, very durable, as the dilapidated state of the old castles of Penrith and Brougham in the neighbourhood clearly show. (16) *St. Bees' Stone:* Similar to the Penrith Sandstone in colour, durability, etc. (17) *Stancliffe Stone:* Similar to the Darley Dale stone (*q.v.*) (18) *Wheatwood Stone:* A sandstone from Yorkshire, varying from a very fine grain to a coarse grit; durable. Examples: Whitby Abbey and the new University Library at Cambridge.—II. STONES USED IN HEAVY MASONRY. (1) *Aberdeen Granite:* A grey granite, extremely hard and durable. Practically the whole city of Aberdeen is built of this stone, and it is also much used elsewhere, both for heavy work and also for ornamental work, on account of its fine appearance when polished. (2) *Cornish Granite:* One of the finest varieties of granite for heavy work. Examples of this are found at Portland Breakwater, Keyham Dock, Commercial Docks (London), the London Docks, and Waterloo Bridge. From the granite found at Cheesewring, Westminster Bridge and the Thames Embankment are built. (3) *Dartmoor Granite:* A greyish granite used in large work—*e.g.* London Bridge. (4) *Mount Sorel Granite:* From Leicestershire. A very hard granite, difficult to quarry, and therefore expensive. Much admired for its warm rose tint, and therefore used in ornamental work, as well as in work requiring great durability, such as paving. (5) *Peterhead Granite:* Fine red granite of very close texture. It can be obtained in very large blocks, and is therefore suitable for columns. A good example of the latter can be seen in the columns of the Carlton House Club in London, and students should also inspect a large vase of the same stone in the vestibule of the Museum of Practical Geology. (6) *Shap Granite:* A very fine granite, with large crystals of red felspar. This stone is regularly worked for ornamental purposes, and takes a very high polish. (7) *Syenite:* This is an igneous rock very similar to granite, from which it is distinguished by the fact that little or no free quartz is found in it. Mount Sorel in Leicestershire is one of the best known English quarries. A fine syenite from Norway, whose colour varies from grey to dark green; is very much used in England for panels and decorative work, especially in the fronts of many modern hotels. This syenite contains large crystals of iridescent felspar, and its appearance when polished is extremely fine; the crystals of felspar reflect the light to a very considerable distance. (8) *Porphyry:* An igneous rock containing large crystals, chiefly used for ornamental purposes. An English example is known as Luxullianite, from Luxullian, in Cornwall. This stone is used in the sarcophagus of the Duke of Wellington at St. Paul's Cathedral. A more celebrated porphyry is the Egyptian one quarried near the first cataract of the Nile, and much used in ancient work in Egypt. (9) *Basalt:* A dark-coloured, heavy, and close-grained eruptive rock. Chiefly used for ornamental purposes, but occasionally for heavy building work.—III. Most of the above stones are frequently used for decorative purposes, as has been noted under each example. The following, however, are rarely used for any other purpose than decoration:—(A) *Alabaster:* This is a form of GYPSUM (*q.v.*) It takes a fair polish, and is very often beautifully veined; but as it is very soft and not at all durable, it is only suitable for internal

decorative work, such as panels, vases, etc. (B) *Marbles:* A marble is a granular limestone capable of taking a high polish. Marbles used in statuary work are treated elsewhere. *See* STATUARY MARBLES. The following are amongst the commonest forms used in building:—(1) *Anglesea Marble:* A grained marble, containing also a certain amount of serpentine (*q.v.*) (2) *Black Marble:* Found in Ireland, at Galway and Kilkenny. (3) *Derbyshire Marble:* Occurs in a variety of colours, and is frequently finely marked. Much used in mantelpieces and other decorative work. (4) *Devonshire Marbles:* Both black and white marbles are found in North Devon. In South Devon marbles of various shades—grey, red, green, and rose—are found, and are worked for columns, panels, chimneypieces, etc. (5) *Purbeck Marble:* Blue or grey, containing shells and other fossils. Some good examples of this are seen in the Temple Church, London. (6) *Foreign Marbles:* There are an enormous number of these. Some of the best forms occur in Greece and in Italy, at Carrara and Massa, near the Bay of La Spezzia. (7) *Serpentine:* A fine stone of dark grey, variegated with other shades. Worked at the Lizard, in Cornwall, for columns, panels, and many varieties of small decorative work. The so-called "Connemara marble" is a serpentinous marble.—The geological nature of the above rocks will be found described under the respective headings, as are also the constituent minerals of each rock.

Building Up (*Eng.*) Making an object of a number of small pieces firmly attached together; thus large patterns are built up of glued pieces, and forgings are sometimes made out of a number of small pieces of iron welded together. To obtain the greatest strength, the component pieces are first arranged with the grain or fibre of alternate layers at right angles to each other.

Built Up Ribs (*Carp.*) Ribs (*q.v.*) composed of curved pieces nailed together side by side. A laminated truss.

Bulb (*Botany*). A specialised subterranean bud, consisting of a disc (stem) bearing overlapping succulent leaves.

Bulb Bars (*Eng.*) Bars of iron rolled with a bead parallel to their length, usually along one edge.

Bulge. An irregular protuberance.

Bulging Stress (*Eng., etc.*) The force tending to produce a bulge in sheets or plates, whether curved (as in a boiler) or flat.

Bulkhead. One of the upright partitions that divide the cabins in a ship; or that divide the hold into separate watertight compartments. The COLLISION BULKHEAD is that nearest the stern or bow of the ship.

—— (*Carp.*) The matchboarded space which lights the basement under the stall board (*q.v.*) in a shop; also a general term for a partition.

Bulla (*Archæol.*) A boss of metal, or even leather, worn by freeborn and noble Roman children until the age of seventeen, when they assumed the *toga virilis*.

Bull Dog (*Met.*) A mixture containing iron oxides, silica, etc., used for lining puddling furnaces (*q.v.*) The operation is termed "fettling."

Bulling Bar (*Mining*). A bar used as a ramrod for filling cracks with clay before blasting.

Bullion (*Bind.*) The same as boss (*q.v.*)

Bullion (*Cost.*) Heavy ornamental fringe, generally consisting of silk fabric covered with gold or silver wire.

—— (*Met.*) Precious metal in the mass as distinguished from manufactured articles or coined money.

—— (*Mining*). Pig lead which contains a certain amount of precious metal not yet separated by refining.

Bullion Point (*Glass Manufac.*) The extreme end of a bulb of glass which is being worked on a blowpipe. It is important that the bullion point be kept in line with the blowpipe during the early stage of manipulation.

Bullnose. A small metal rabbet plane, having the mouth or opening close to the front.

Bullnosed Bricks (*Build.*) Bricks having one angle on the end rounded off.

Bullnosed Step (*Carp. and Join.*) A step with a rounded end.

Bullock Gear, Horse Gear. The device used for driving machinery by animal power; the animal rotates a vertical shaft by means of a long lever, to which it is yoked.

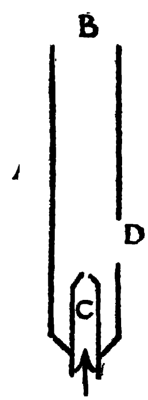
Bull's Eye (*Build.*) A small circular opening or window.

Bundle. In the cotton trade, a standard weight of cotton yarn consisting of a variable number of hanks, according to the counts, but always weighing 10 lb. in the grey state. A shipping bundle is sometimes 5 lb.

—— (*Linen Manufac.*) A standard length of 60,000 yards, containing two hundred cuts of yarn, is called a bundle, and it is by the bundle that linen yarn is usually sold.

Bunkers (*Eng.*) The spaces in which the coal for use on the voyage is kept in a steamship; sometimes the term is applied to a similar receptacle for use on land.

Bunsen Burner. A form of gas burner used when a hot but non-luminous flame is required—*e.g.* burners for laboratory purposes, gas stoves and furnaces, and for heating the MANTLE (*q.v.*) employed in the various forms of incandescent gas lighting. The essential principle of this form of burner is the mixing of the gas, before it reaches the jet where it burns, with a sufficient supply of air to secure complete combustion. The gas enters by a tube C, and in rushing up the tube A it draws in a continuous supply of air through the opening D, the size of which can be regulated in order to control the air supply. The mixture burns at B. In gas stoves the end B is closed, and a row of holes is pierced along the tube A, at each of which a portion of the gas burns with a small blue flame. Occasionally the burner "strikes back"—*i.e.* the gas catches light and burns inside the tube A. When this happens, the gas should be turned off and relit, as acetylene and other gases are produced, which are injurious and liable to explode.



BUNSEN BURNER.

Bunsen Cell. *See* CELLS, PRIMARY.

Bunsen Flame. *See* FLAME.

Bunsen's Ice Calorimeter (*Heat.*) Apparatus for measuring the heat given out by a body in cooling to 0° C. by observing the amount of ice melted by it. The ice is protected from external action by the vessel in which it is contained being surrounded by a second vessel, also containing ice; this absorbs any heat from the room, and prevents it from reaching the inner ice chamber.

Bunsen's Photometer (*Light*). Essentially a sheet of paper with a translucent grease spot in the centre. When the sheet is equally illuminated on both sides, the spot is indistinguishable; if the spot is viewed from the side which is less illuminated than the other, it appears brighter than the paper; if viewed from the brighter side of the paper, it appears darker, owing to the light passing through the spot instead of being reflected. *See* PHOTOMETERS.

Bunsen Valve. A simple arrangement for allowing gas to pass out of an apparatus and preventing air from entering. It is made by attaching a piece of rubber tubing to the end of the glass delivery tube, cutting a slit in the rubber longwise above the delivery tube, and pushing a piece of glass rod into the rubber tube as far as the slit, so that the rod extends the whole length of the slit.

Bunter (*Geol.*) A German name originally applied to the variegated and spotted strata occurring in the Upper New Red rocks. It has now come to be used for the lower division of the Trias (or Upper New Red), which commonly shows the variegation to which it owes the name. Similar variegations, however, occur in the sandstones of the Lower New Red, or Dyas, as well as in other rocks which have been formed under desert conditions.

Buntons (*Mining*). Horizontal timbers across a shaft.

Buoy (*Marine Eng.*) A hollow float anchored to the sea bottom; used to mark a shoal or to provide moorings for a vessel.

Buoyancy (*Phys. etc.*) Loss of weight due to immersion in a fluid: the upward force exerted on a body by a fluid in which the body is wholly or partially immersed. The force is equal to the weight of the fluid displaced, and in the case of a floating body is equal to the weight of the body itself. *See also* RESERVE OF BUOYANCY.

Bur. *See* BURR.

Burden (*Met.*) The charge given to a furnace. "Light burden" denotes excess of fuel; "heavy burden," excess of ore.

Burdiehouse Limestone (*Geol.*) A band of limestone of peculiar type, which occupies a position about halfway up the Lower Carboniferous rocks of the basin of the Forth. It is a finely laminated rock, which consists of alternate thin bands of chemically precipitated oolitic limestone, and others of a bituminous shale of the nature of oil shale. It underlies the chief part of the Oil Shale Series. It has long been celebrated on account of the well-preserved fossils which have been obtained from it.

Burette (*Chem., Phys.*) A graduated glass tube with some form of tap or stopcock; it is fixed vertically in a stand, and used for measuring a volume of liquid which has to be run into a vessel placed beneath the stopcock. Burettes capable of measuring from 50 to 100 cubic centimetres are much used in volumetric analysis.

Burganet, Burgonet (*Armour*). A helmet with a small visor, so constructed as to permit the head being turned either to right or left without the neck becoming exposed. First used by the Burgundians.

Burial (*Hygiene*). Places used for the purpose are sometimes offensive. This condition is brought about by the decomposition of animal matter, and is intensified by the agglomeration of bodies. Sickness is frequently caused by the contamination of both air and water. Burial grounds are under the control of the sanitary authority or burial board, who are authorised to make bylaws for the management, etc., thereof. They fall far short of cremation in hygienic value. *See also* CREMATION *and* SANITATION (DISPOSAL OF THE DEAD).

Burin *or* **Graver** (*Engrav.*) An instrument of tempered steel, with a square or lozenge-shaped point, used for engraving copperplates. The furrows cut by the square-pointed instrument are broad, and, not being deep and therefore not holding much ink, they give a grey print. The handle of the instrument is flat on one side, so that it can be held close to the plate when being used.

Burlap (*Dec.*) A coarse fabric stained in a variety of colours, and pasted upon a wall to give a uniform but broken surface. Hand stencilled friezes done directly upon the material are often used where a refined and uncommon decoration is desired.

Burner (*Motor Cars, etc.*) Oil (paraffin, petrol, etc.) is forced by air pressure or a small pump through coils of heated tubing, in which it becomes vaporised, to a gas burner, usually of the Bunsen type, giving a hot flame with very complete combustion. The vaporising coils must be heated when first starting the burner; but, once started, they are kept hot by the burner itself. *See also* OIL FUEL.

Burnett's Fluid. A solution of zinc chloride of specific gravity 2. It is used as an antiseptic.

Burnett's Process (*Eng., etc.*) The soaking or impregnation of timber with a dilute solution of zinc chloride, to increase its powers of resisting atmospheric influences.

Burning (*Eng., Met.*) Oxidation of iron by keeping it too long at a welding heat. Burnt iron is practically useless.

Burning Back (*Motor Cars*). The lighting of the vapour in an oil burner behind the jet in the tube of the burner. It is a somewhat dangerous occurrence, and the supply of fuel should be cut off at once, and the burner relighted after it has cooled down slightly.

Burning In Kiln (*Glass Manufac.*) A kiln used for burning in stain or enamel decorations on glass. It is generally heated by gas mixed with atmospheric air.

Burning Off (*Dec.*) Old paint work burnt off with a blow lamp.

Burning On (*Foundry*). A process of adding a fresh part to an injured or incomplete casting. A stream of molten iron is allowed to run through the mould of the new part of the casting until the surface where the junction is to be becomes fused. The flow is then stopped and the fluid metal in the mould allowed to cool. The process produces a kind of "weld."

Burning Out of a Machine (*Elect. Eng.*) The destruction of the insulation by overheating of the conducting wires of a dynamo, or motor, when too large a current passes.

Burnish (*Bind.*) The gloss on the edges of a book produced by a burnishing tool.

Burnisher (*Engrav.*) An instrument of polished steel with a blunt edge, used to reduce, soften, or remove faulty lines on an engraved copperplate.

Burnishing. Producing the highest state of finish on a surface by means of rubbing with special tools, usually of very bright smooth steel; but various stones, *e.g.* agates, are also used.

—— (*Photo.*) Effected by passing prints between polished steel rollers, or else by allowing the print to dry in close contact with a polished sheet of glass or ferrotype iron.

Burnt Ballast (*Build.*) Clay that has been burnt (calcined).

Burnt Iron *or* **Steel** (*Eng.*, *Met.*) Metal which has absorbed an excess of carbon by contact with the fire at a great heat. It is valueless.

"Burnt Out" Lace. Imitation guipure and similar lace made upon the embroidery machine. A woollen foundation is used to build the lace upon, this foundation being afterwards "burnt" or dissolved away in a solution of caustic soda or other chemical.

Burnt Sienna (*Paint.*) Sienna earth is burnt and is converted into a pigment of a fine orange-red colour. Used both in oil and water-colour painting. *See also* SIENNA.

Burnt Umber (*Paint.*) Umber is burnt and ground, producing a pigment of a reddish-brown colour. *See also* UMBER.

Burr (*Eng.*) The turned up and ragged edge of a piece of metal after cutting or grinding.

—— (*Engrav.*) The ridge of metal raised on the edges of a line by the cutting tool, generally removed, partially or altogether, by the scraper.

Burra Burra Copper (*Met.*) A blue form of Malachite or copper carbonate; a copper ore from Australia.

Burrs. *See* BRICKS.

Bursting (*Eng.*, *etc.*) As applied to pulleys and grindstones, it denotes a fracture due to the stresses set up by centrifugal forces when the object is rotating at a high speed.

Bush (*Eng.*) An anti-friction lining for a bearing, in one piece, very often cast *in situ*.

Bushel. *See* WEIGHTS AND MEASURES.

Buskin. (1) A half boot reaching to the knee, worn in classic times. Diana, Bacchus, and Mercury are frequently represented wearing buskins. (2) The thick-soled boot worn by actors in ancient Athenian tragedy, known as "Cothurnus," and distinct from the "sock" or low shoe worn by comedians. Hence "buskin" refers to the tragic art. (3) Also worn in the middle ages, especially by kings at coronation.

Bustle (*Paint.*) The opposite to repose. Absence of quiet and harmonious tones in composition of a picture.

Butanes, C_4H_{10}. There are two isomeric butanes—*viz.* NORMAL BUTANE, $CH_3CH_2CH_2CH_3$, and SECONDARY BUTANE (also called trimethylmethane), $\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>CH-CH_3$. The first boils at 1°, and the second at −17°. Normal butane occurs in petroleum, and can be obtained by heating ethyl iodide with sodium. The second is obtained from tertiary butyl alcohol by making the iodide, and reducing this with nascent hydrogen. They belong to the paraffin series of hydrocarbons.

Butt (*Leather Manufac.*) The best part of the tanned hide; the back, after the belly and shoulders have been cut off. Used for soles of boots, belting, and heavy harness.

Butt Coupling (*Eng.*) *See* BOX COUPLING.

Butt Ended Spoke (*Cycle*). A spoke which has been thickened at the end before cutting the screw thread on it, in order that the strength of the screwed part may be as great as that of the rest of the spoke.

Butter (*Foods*). Is made from the fat of milk by churning. It is an article of food unfortunately very liable to adulteration. This is ordinarily done by admixture with other animal or vegetable fats. Occasionally potato and other starches are added. Water in quantity exceeding 16 per cent. is also regarded as adulteration. Composition: Fat, 82 to 87 per cent.; casein, milk, sugar, ·5 to 1·2 per cent. together; water, 9 to 15 per cent.; ash (including salt), less than 2 per cent. if the butter is "fresh," or 2·1 per cent. and over if "salt." The fat consists of compounds of glycerine with the following fatty acids: palmitic, stearic, oleic, butyric, caproic, etc. Butter owes its distinctive characteristics to about 7·8 per cent. of the glycerine compounds of butyric and caproic acids, etc. Butter is also adulterated with preservatives and colouring matter. The usual preservatives are boric acid and borax, or both. The colouring matter may be annatto, or "butter yellow," which is dimethylamidoazobenzene.

Butterfly Valve (*Eng.*) A couple of flap valves with their joint between them, like a common hinge.

Butt Joint (*Carp.*, *etc.*) A joint at right angles to its length. A plain joint without tongue or groove.

Button (*Eng.*) The piece punched out of a plate by the punching machine.

—— (*Watchmaking*). The knob fixed to the winding stem of a keyless watch.

Button Headed Screws (*Eng.*) Small screws with hemispherical heads.

Buttress (*Build.*) A mass of brickwork or masonry to prevent a wall being overturned. It acts as a permanent strut or SHORE (*q.v.*), and resists any thrust in an outward direction, *i.e.* at right angles to the plane of the wall.

Buttress Threads (*Eng.*) A thread whose section is a right-angled triangle, one face being at right angles to the shaft. They are used in screws which are to resist a force which is always in one direction.

Butt Riveting (*Eng.*) A riveted joint where the plates touch at the edge only, and a strip overlaps and is riveted to both of them.

Butt Strip (*Eng.*) The strip of plate used to cover a butt joint.

Butyl Derivatives. Compounds containing the group C_4H_9, derived from either of the two butanes (*see* BUTANES) by subtracting one atom of hydrogen. Thus isobutyl carbinol, the principal constituent of ordinary amyl alcohol (*q.v.*), would be $C_4H_9.CH_2OH$ $= \begin{matrix}CH_3\\CH_3\end{matrix}\!\!>CH.CH_2.CH_2OH$.

Butyric Acids, $C_4H_8O_2$. Only normal butyric acid, $CH_3CH_2CH_2COOH$, is important. It is a rancid-smelling liquid boiling at 163°; soluble in water, alcohol, and ether. With alcohol and sulphuric acid it gives a smell of pineapples on warming. It is the characteristic acid of butter (*q.v.*) Formed in the fermentation of starch, sugar, and lactic acid by certain bacilli; on this account it is found in the

intestines. May be synthesised from ethyl aceto-acetate (*q.v.*) The smell of rancid butter is largely due to this acid.

Butyrin (*Chem.*)

$$\begin{array}{l} CH_2OOC.C_3H_7 \\ | \\ CHOOC.C_3H_7 \\ | \\ CH_2OOC.C_3H_7 \end{array}$$

Is the glycerine compound of normal butyric acid; forms one of the fats of butter (4·67 per cent. of butter fat).

B.W.G. (*Eng.*) The Birmingham Wire Gauge. *See* WIRE GAUGES.

By Products (*Gas Liquor*). *See* GAS MANUFACTURE *and* WASTE PRODUCTS.

Byssus (*Zoology*). A mass of adhesive threads secreted by a gland within the body of many bivalve shellfish. The byssus ("beard") serves as an organ of attachment.

Byzantine Architecture (*Architect.*) This style of architecture was developed at Byzantium in the fifth century A.D. The chief characteristics of Byzantine architecture are the extensive use of the dome and pendentive over large spaces: interiors richly treated with marbles, mosaics, and incised ornament. The finest example is the church of Hagia Sophia (A.D. 532—538) at Constantinople.

Byzantine Art. Greek and Roman art modified by Christian thought. Developed at Constantinople about 300 A.D., and during the Middle Ages was widely identified with all kinds of art, especially in Italy. It depended much on colour for its effect, and abounded with Christian emblems.

Byzantine Binding. Binding executed by the monks principally, before the invention of printing. Books being at this time extremely valuable, the bindings were often richly ornamented with paintings, gold and silver work, and even jewels.

Byzantines (*Coins*). *See* BEZANT.

C (*Chem.*) Symbol for CARBON (*q.v.*)

—— (*Music*). The first note in the scale of C. Its sol-fa name is Do, Doh, or Ut.

Ca (*Chem.*) Symbol for CALCIUM (*q.v.*)

Caaba. The name given to a stone building situate within the great Mosque at Mecca. Regarded with great veneration by Mohammedans as contain-the Black Stone or Keblah, presented by the Angel Gabriel to Abraham on the occasion of the building of the original Caaba. The entire building is sometimes called by this name.

Cab (*Eng.*) The shelter provided for the driver on a locomotive.

Cabinetmaking. The construction of the better class of furniture. It is distinguished from JOINERY by the greater variety of woods used, more elaborate ornamentation and finish, the use of VENEER (*q.v.*), and the difference in the construction of the joints. These are often much less scientific than in joinery, as neatness and general finish are of greater importance than strength.

Cabinet Picture. A small painting, generally highly finished, and admitting of close inspection.

Cabinet Size (*Photo.*) A print of which the size when finished is about 4 in. by 6 in., *i.e.* somewhat less than a HALF PLATE (*q.v.*)

Cable (*Architect.*) A convex moulding used on the lower part of the flutes of a column. The cables are usually one-third the length of the shaft in height. They were not used in Greek work.

—— (*Elect. Eng.*) A heavily insulated wire or set of wires, often protected from injury by a very strong covering. Used to convey large currents for lighting and power, or for the small currents required in telegraph or telephone work. In the latter cases a number of separately insulated conductors are often included in the one cable.

—— (*Eng.*) A stout rope of either hemp or steel. The name is also applied to a chain, especially that to which the anchor of a ship is attached.

—— (*Measure of Length*). *See* WEIGHTS AND MEASURES.

Cabled Column (*Architect.*) A column in which cables are used. It is also known as a RUDENTED COLUMN. *See* CABLE.

Cable Laid Rope (*Eng.*) A rope formed of several ordinary ropes, the whole being twisted in the direction opposite to the strands of the individual ropes.

Cable Moulding (*Architect.*) An enriched moulding consisting of a torus carved to represent a rope, used in Norman architecture.

Cable Railway (*Civil Eng.*) A cable extending the whole length of the track is placed either overhead or underground in a slotted conduit. The cars are drawn along by means of a clutch, which grips the cable when required, and releases it when the car is to stop. Cable railways are most suitable for short straight inclines.

Cable Tramcars (*Civil Eng.*) These use the central slot system. The cable runs in a roomy conduit under the slot, and is supported by pulleys 30 or 40 ft. apart. The clutch, when it seizes the cable, raises it above the level of these pulleys, and so passes them freely. The cable usually runs at 5 to 9 miles an hour. The most extensive system of cable tramcars in Great Britain is that of the city of Edinburgh; two of the most hilly routes in the city have been worked on this system for a long period, and in recent years the whole system has been thus equipped.

Cable Ways (*Civil Eng.*) Overhead cables, suitable for haulage of materials. The cable and gear are carried on trestles, which can, if necessary, be erected on broken and irregular ground, or carried over streams or ravines. The system is extremely useful for the carriage of materials used in the erection of bridges over wide rivers.

Cabling (*Cotton Spinning*). A process of doubling by which separate groups of threads are twisted together, then retwisted together so as to produce a round, even, and strong thread—*e.g.* sewing cotton thread.

Caboched *or* **Cabossed** (*Her.*) Affronté or full faced. When the head of the animal in a heraldic device is placed looking at the spectator and the neck is concealed; also called TRUNCKED.

Cabochon. A precious stone cut into plano-convex or concavo-convex form and polished, its natural shape being little altered; generally a garnet, ruby, sapphire, or amethyst.

Cacao (*Botany*). A name often applied to *Theobroma Cacao*, a tree of tropical America. *See* COCOA *and* THEOBROMINE.

Cachou de Laval. *See* DYES AND DYEING.

Cacodyl (*Chem.*) This word is used in two ways. (1) It is applied to the monovalent group $\begin{matrix}CH_3\\CH_3\end{matrix}{>}As-$, which has no independent existence, but enters into a number of compounds called after it, cacodyl compounds; *e.g.* $(CH_3)_2AsCl$ is CACODYL CHLORIDE. (2) It is applied to the compound formed by the union of the group $\begin{matrix}CH_3\\CH_3\end{matrix}{>}As-$ with another group like it, and thus having the formula $[(CH_3)_2As-As(CH_3)_2]$. This compound CACODYL, obtained by heating cacodyl chloride with zinc, is a liquid which boils about 170°: takes fire in air: its smell may induce vomiting: forms with slow access of air CACODYL OXIDE $\{(CH_3)_2As\}_2O-$, a compound also produced when arsenious oxide is distilled with potassium acetate. The oxide boils about 150°, has an appalling smell, and behaves like a basic oxide. CACODYL CHLORIDE, $(CH_3)_2AsCl$, is obtained by action of hydrochloric acid on cacodyl oxide; it is a liquid boiling about 100°, and its vapour produces terrible effects on the eyes and face when inhaled. CACODYL CYANIDE, $(CH_3)_2AsCN$, obtained by heating the chloride with mercury cyanide, is a solid melting at 33°; its vapour is fearfully poisonous. CACODYLIC ACID, $(CH_3)_2AsO.OH$, is formed by the action of mercuric oxide and water on cacodyl oxide; it is a deliquescent crystalline solid. Its sodium salt is used in medicine; it is less poisonous and has the same use as arsenious oxide. The group $\left(\begin{matrix}CH_3\\CH_3\end{matrix}{>}As-\right)$ behaves like a monovalent metal, and it is therefore an example of a compound radical (*q.v.*)

Cadaverine (*Chem.*). $CH_2{<}\begin{matrix}CH_2-CH_2-NH_2\\CH_2-CH_2-NH_2\end{matrix}$ (*Pentamethylenediamine*). Is found in putrefying corpses and in many kinds of putrid flesh, it is also found in pure cultures of the cholera bacillus. It is a colourless syrupy liquid boiling about 175°: has a peculiar smell: fumes in air: soluble in water and alcohol. It forms salts with acids, and is a diacid base. It is not poisonous except in very large doses. Has been made artificially. It is a PTOMAINE (*q.v.*)

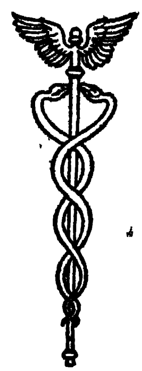
Cadence (*Music*). The close of a phrase, and the term applied to the two final chords of a musical phrase. There are four kinds. (1) PERFECT, when the chord roots are Dominant to Tonic. (2) Imperfect, when they are Tonic to Dominant. (3) Plagal, when the roots are Subdominants to Tonic. (4) INTERRUPTED, when the Dominant proceeds to some other root than Tonic.

Cadenza (*Music*). A free figure (generally written in small notes) introduced before a close.

Cadmium (*Chem.*), Cd. Atomic weight, 112. A white metal with bluish tinge; melts at 320°; boils about 770°; its vapour density shows it to have a monatomic molecule (*q.v.*) Easily soluble in hydrochloric, sulphuric, and nitric acids; burns in air when strongly heated, forming a brown oxide, CdO. It occurs along with zinc, and comes over with the first portions of that metal when distilled from its ores. To obtain cadmium, these first portions are redistilled and the product dissolved in hydrochloric acid and precipitated by sulphuretted hydrogen, when the yellow cadmium sulphide is thrown down. The sulphide is dissolved in strong hydrochloric acid, precipitated by sodium carbonate, the carbonate heated, and the resulting oxide distilled with carbon. Cadmium belongs to the same chemical family as zinc, which it closely resembles; the chief distinction is the yellow sulphide insoluble in dilute hydrochloric acid. It forms a constituent of FUSIBLE METAL (*q.v.*), and certain of its compounds furnish valuable pigments.

Cadmium Yellow (*Dec.*) A bright rich yellow pigment made from a salt of the metal cadmium by passing through it sulphuretted hydrogen. This yields the pigment which is sulphide of cadmium. It is permanent in oil, turpentine, water, and other vehicles, and may be mixed with any other pigments excepting white lead, the chromes, and those containing lead or (such as emerald green) copper. Made in three shades. Employed by artists and decorators, and rapidly increasing in use among the latter.

Caduceus (*Archæol.*) The staff carried by Mercury and symbolical of peace and prosperity. About it coiled two serpents, and to the top were attached extended wings.



CADUCEUS.

Cadus (*Archæol.*) A large jar of terracotta, used by the ancients for wine, oil, etc.

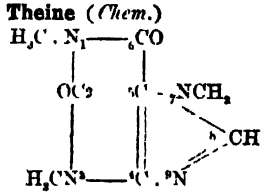
Cæcum (*Zoology*). A blind outgrowth from the junction of the ileum and the colon. It is largest in herbivorous animals. The end of the cæcum is termed the VERMIFORM APPENDIX.

Cælatura (*Art*). Latin for the art of carving bas reliefs, especially in metal: chasing or engraving.

Caen Stone. *See* BUILDING STONES.

Cæsium, Cs. Atomic weight, 133. A white metal spontaneously inflammable in air; it decomposes water. It belongs to the same group of elements as potassium, which it closely resembles chemically. This was the first metal discovered by spectrum analysis. It occurs in many mineral waters, and was first discovered by Bunsen in the waters of Dürkheim. Its spectrum is characterised by two bright blue lines, and from this circumstance it derives its name.

Caffeine *or* **Theine** (*Chem.*)



Forms long silky needles; melts at 233°; sparingly soluble in cold water, readily in hot. It is a feeble base. Acts on the heart, and is a diuretic. It is contained in tea (3 to 5 per cent.), coffee (1·3 per cent.: coffee-leaves much more). These beverages owe much of their effect to this substance. It may be obtained from tea by treatment with hot milk of lime, evaporating, extracting with chloroform, evaporating the extract, and crystallising from water. Test, similar to murexide test for uric acid (*q.v.*) Gives precipitates with alkaloid reagents (*q.v.*)

Cage (*Eng.*) The chamber or receptacle of a lift or winding gear of a mine; it is often made large enough to accommodate a considerable number of men or of waggons containing the material which is being removed from the mine.

Cage Valve (*Eng.*) A valve consisting of a spherical ball fitting into a seat of suitable form, and provided with a cover or cage of bent wire or bars, to prevent the loose ball from rising too far out of the seat.

Cainozoic (*Geol.*) Another name for the Tertiary period. It is correlative with AZOIC, EOZOIC, PALÆOZOIC, and NEOZOIC (*q.v.*) In Britain it is usually applied to all strata of newer date than those of Cretaceous age.

Cairn (*Archæol.*) A mound or heap of stones generally of conical shape. Sometimes erected over the graves of the dead or in commemoration of some remarkable event. Cairns are also erected in mountainous districts to serve as landmarks and to indicate the position of frontiers or other boundaries.

Cairngorm (*Min.*) A dark brown variety of QUARTZ (*q.v.*) much used in jewellery. The varieties used for this purpose are naturally almost opaque in the mass, but the colour is largely discharged by boiling in oil.

Caisson (*Eng.*) A water-tight chamber sunk into the ground under water. Masonry operations such as laying the foundations of bridge piers are carried on from within.

Caithness Flags (*Geol.*) The grey, micaceous, and somewhat bituminous flagstones which form a large part of the Orcadian Old Red Sandstone (the true Middle Old Red) in Caithness and Orkney. It is much quarried for pavements, and for any other purpose to which flagstones are usually applied. It yields a considerable variety of the fossil remains of the fishes which lived in the inland lakes of the period between that of the Upper Old Red and the Caledonian Old Red.

Cajeput (*Botany*). *Melaleuca leucadendron* (order, *Myrtaceæ*). A stimulant oil distilled from the leaves. The plant is a native of the Moluccas.

Caking Coal. Coal with much bituminous matter. Used in forges and in gasmaking.

Calabar Bean (*Botany*). *Physostigma venenosum* (order, *Leguminosæ*). A West African plant whose ripe seed yields the alkaloid PHYSOSTIGMINE, used in medicine.

Calamine (*Min.*) Carbonate of zinc; $ZnCO_3$; $ZnO=64{\cdot}8$, $CO_2=35{\cdot}2$ per cent. Called SMITHSONITE by some American writers and others. Commonly found as incrusting masses. It is the most important ore of zinc. Colour white, greenish, or brown, but very variable. Its crystallographic form is rhombohedral. From Cornwall, Cumberland, Derbyshire, Dumfriesshire; much also comes from Silesia, Carinthia, Spain, United States, etc.

Calando (*Music*). Decreasing the sound. When followed by *a tempo* it is used in connection with speed and means decreasing the pace.

Calantica (*Archæol.*) A headdress of Egyptian origin, consisting of a close-fitting cap fastened by a band passing round the head.

Calathus (*Archæol.*) A wickerwork basket used by the Grecian women to hold their wool for spinning.

Calcareous Rocks (*Geol.*) Rocks consisting wholly, or in part, of carbonate of lime. The term includes all limestones and most true marbles, as well as a considerable variety of sedimentary rocks into whose composition carbonate of lime enters.

Calceus (*Archæol.*) A shoe or half boot worn by the Romans. It differed according to the rank or official position of the wearer.

Calciferous Sandstones (*Geol.*) A term applied to the lower part of the Lower Carboniferous Rocks of the south of Scotland before their true geological position was known. They are chiefly of estuarine origin. They contain but little lime, and consist largely of shales. The upper part of the rocks in question is the horizontal equivalent of the Mountain Limestone, while the lower part is contemporaneous with the Lower Limestone Shales. Important groups of volcanic rocks occur in these strata in Scotland.

Calcination *or* **Roasting** (*Met.*) Heating an ore without causing fusion. It is an important operation in connection with many ores, whereby various constituents (*e.g.* carbon, sulphur, arsenic, etc.) are converted into gaseous substances and expelled in this form; in addition to this object, some ores are calcined in order to effect the oxidation of the metal itself.

Calcining Furnace (*Met.*) A reverberatory furnace (*q.v.*) used for calcination or roasting.

Calciphyres (*Geol.*) A term sometimes applied to certain marbles which have undergone a considerable amount of METAMORPHISM (*q.v.*) and in which new silicates have consequently been developed.

Calcite (*Min.*) Calcium carbonate in the rhombohedral form (*cf.* ARAGONITE), $CaCO_3$, $CaO = 56$, $CO_2 = 44$ per cent. It occurs crystallised in a great variety of forms, and massive as STALACTITES and incrustations in caves. The pure variety, ICELAND SPAR, is very valuable on account of the demand for it for the manufacture of polariscopes. ORIENTAL ALABASTER is a stalagmitic variety, and is used under the name ALGERIAN ONYX for ornaments. Calcite is a very common gangue metal (*q.v.*) in metalliferous veins. Calcite shows very marked double refraction. It is very widely distributed all over the world.

Calcium, Ca. Atomic weight, 40. One of the most abundant elements; contained in chalk, marble, limestone, dolomite, alabaster, selenite, etc. (*q.v.*) It is obtained as a brilliant white crystalline solid by heating calcium iodide with excess of sodium in an iron crucible. The excess of sodium, which, while molten, serves as a solvent for the calcium, is removed by gradually adding the contents of the crucible, when cold, to absolute alcohol. Calcium burns in air to form the oxide CaO (QUICK LIME), and rapidly combines with water, forming SLAKED LIME, $Ca(OH)_2$. Heated in hydrogen it forms the white hydride CaH_2.

Calcium Compounds. CALCIUM OXIDE, CaO (QUICK LIME), a white amorphous solid, combines with water to form the hydroxide $Ca(OH)_2$. It is obtained by heating the carbonate or the nitrate; is a typical basic oxide. CALCIUM HYDROXIDE, $Ca(OH)_2$ (SLAKED LIME), is a white powder sparingly soluble in water. The clear solution is called LIME WATER; the turbid mixture of the hydroxide and water is called MILK OF LIME, used in making mortar (*q.v.*) Both solid and solution absorb carbon dioxide from the air. CALCIUM CHLORIDE, $CaCl_2$: A white deliquescent solid, prepared by dissolving the carbonate in hydrochloric acid and evaporating to crystallisation when $CaCl_2 6H_2O$ is deposited. On heating these crystals, $CaCl_2$ remains. Combines with ammonia gas to form $CaCl_2 8NH_3$. Used as a drying agent. CALCIUM CARBONATE, $CaCO_3$: Natural forms are

chalk, limestone, marble, calcite, aragonite (*q.v.*) Prepared by adding sodium carbonate solution to calcium chloride solution and washing the precipitate with water (PRECIPITATED CHALK). Solubility in water less than 1 in 10,000; but in presence of carbon dioxide dissolves readily, owing to formation of CALCIUM ACID CARBONATE, $Ca(HCO_3)_2$. It is the presence of this latter compound that causes TEMPORARY HARDNESS in water. As it is decomposed on boiling or addition of lime water, these operations remove temporary hardness. Calcium carbonate is decomposed, on heating, into quick lime, CaO, and carbon dioxide; also it dissolves in acids forming carbon dioxide, water, and the calcium salt of the acid. CALCIUM SULPHATE, $CaSO_4$: Usually met with as $CaSO_4 2H_2O$. *See* GYPSUM, ALABASTER, SELENITE. A white solid soluble to extent of 1 in 480 of water. When present in water it causes PERMANENT HARDNESS. May be prepared by adding sulphuric acid to a solution of calcium chloride and washing the precipitate. When *Gypsum*, $CaSO_2 2H_2O$, is heated, it forms PLASTER OF PARIS, $2CaSO_4 . H_2O$, which, when mixed with water, "sets," owing to re-formation of $CaSO_4 2H_2O$. The sulphate heated with carbon forms CALCIUM SULPHIDE, CaS –, a white powder which, when exposed to sunlight and then removed to a dark room, becomes luminous (CANTON'S PHOSPHORUS). CALCIUM PHOSPHATE, $Ca_3(PO_4)_2$ (*see* PHOSPHORITE, APATITE, ESTRAMADURITE), is the principal constituent of bone ash (*q.v.*) May be prepared by adding ammonia and solution of sodium phosphate to solution of calcium chloride. White solid, insoluble in water and soluble in acids. When treated with sulphuric acid according to the equation $Ca_3(PO_4)_2 + 2H_2SO_4 = CaH_4(PO_4)_2 + 2CaSO_4$, the resulting mixture of calcium acid phosphate and calcium sulphate is called SUPERPHOSPHATE OF LIME, and is largely used as a manure. CALCIUM PHOSPHIDE is obtained along with calcium phosphate when vapour of phosphorus is passed over heated quick lime. Water decomposes it, forming spontaneously inflammable phosphoretted hydrogen, which burns with a bright white light; hence the use of the phosphide for signal lights at sea.

Calender (*Paper Manufac.*) A stack of superimposed rolls used for imparting a polished surface to finished paper.

—— (*Textile Manufac.*) A machine used in the starching and dressing of cotton fabrics. It consists of a number of rollers under pressure and in contact with each other.

Calendered Paper. Paper with a glazed surface, generally used for the printing of illustrated works.

Calender Rollers (*Woodworking*). The rollers by which wood is fed into various forms of woodworking machinery.

Calf (*Bind.*) A superior kind of leather made from calfskin and used in bookbinding. It is frequently coloured or marbled. *See* VELLUM.

——, **Box** (*Leather*). *See* BOX CALF.

Calf Kid. Calfskins dressed with alum, salt, flour, and egg yolk. Afterwards dyed black on grain side. Formerly largely used for uppers of boots.

Calibration (*Phys., etc.*) A determination of the correct value of the graduations of a scale or some measuring instrument; or a determination of the dimensions of an object which is to be used as a standard of measurement.

Caliche (*Chem.*) A name given to CHILI SALTPETRE: naturally occurring sodium nitrate.

Calico. A cloth in which the warp and weft are alternately interlaced, thus forming a strong and firmly bound cloth. It is used in its grey state, also in the dyed, printed, and bleached states. Its method of interlacing is known as a "plain weave." The name is derived from the town of Calicut in India.

Caliga (*Archæol.*) The strong heavy shoe worn by Roman soldiers.

Caliver (*Arm.*) A light gun resembling an arquebus, but having a wider bore. It was used first in the sixteenth century.

Calix (*Archæol.*) A shallow Grecian drinking cup having two handles: hence chalice.

Calking *or* **Caulking** (*Eng.*) Filling the openings of the seams of a ship, boiler, etc., either by burring the edge of the plates or by driving in some substance to fill up the crevices.

Calligraphy. Handwriting or penmanship. Perhaps the finest examples of handwriting are to be found in the manuscripts of the middle ages.

Calliope (*Eng.*) A modulated steam whistle used on American steamboats.

Callipers. A tool for measuring the internal or external diameter of objects. Two varieties, known as INSIDE and OUTSIDE CALLIPERS, are commonly used: these resemble in principle a pair of compasses, but the legs are curved so as to turn the points outward in the first case and inward in the second. A more modern form consists of sliding trammels (*q.v.*) on a straight bar, resembling a pair of beam compasses (*q.v.*) The bar is often graduated, and one of the trammels fitted with a fine vernier (*q.v.*) for exact measurements.

Callipygian Venus (*Art*). The name of a celebrated statue of Venus in the Farnese Palace, Rome.

Calmato (*Music*). Calmly.

Calme *or* **Came** (*Building*). The bars of lead-glazed windows, in which the glass is fixed.

Calomel (*Min.*) Mercurous chloride, HgCl. It is rather a rare mineral; the drug of the same name is an artificially prepared compound. *See also* MERCURY COMPOUNDS.

Calorescence (*Heat, Light*). The absorption by a substance of radiation of a given wave length and its subsequent emission as radiation of less wave length; *e.g.* invisible infra-red radiations absorbed by a piece of platinum foil can cause it to become incandescent: the energy of the long and invisible waves is given off as visible waves of shorter wave length.

Caloric (*Phys.*) Heat was at one time regarded as an elastic fluid, and the name Caloric was used to denote this substance.

Calorie (*Phys.*) The unit of heat generally used in scientific work. It is (for most practical purposes) the amount of heat necessary to raise 1 gram of water through 1° C. For very accurate work it is necessary to specify the exact temperature at which the water is taken, as the specific heat of water varies. The temperature most usually agreed on is 4° C., but other temperatures have been used from time to time.

Calorific Value (*Heat, etc.*) The measure of the amount of heat obtainable from a given weight of fuel. It is usually found by direct experiment, the fuel being completely burnt and the heat evolved measured by some form of calorimeter.

Calorimeter (*Phys.*) An instrument for measuring actual quantities of heat. In its commonest form it consists of a thin metal vessel, in which a known mass of water (or other liquid) is placed. The rise or fall in temperature of this liquid (due to the introduction of a hot or cold body) is observed by means of a thermometer. The vessel is usually protected from loss or gain of heat through radiation by means of an outer vessel. *See also* BUNSEN'S ICE CALORIMETER, STEAM CALORIMETER, *etc.*

Calotte (*Art, etc.*) A term for the smaller section of a sphere, not used in scientific phraseology. Also used to denote the small SKULL CAP of an ecclesiastic.

Calpis (*Pot.*) A Grecian earthenware vessel of large size, having three handles, used for holding water.

Caltrap, Caltrop, *or* **Galltrap** (*Archæol, etc.*) (1) An instrument of iron with sharp projecting points, laid on the ground in battle to wound the feet of the enemy's horses. (2) A trap or gin. (3) Sometimes used as a charge in heraldry.

Calumba Root (*Botany*). *Jateorhiza calumba* (order, *Menispermaceæ*). The tonic drug is prepared from the dried roots of a trailing plant from the forests of East Africa.

Calyx (*Botany*). The outer whorl of floral leaves (SEPALS) in a flower. It has usually a protective function.

Cam (*Eng.*) An eccentric rotating plate, or a projection, or a slotted rotating shaft, used to produce some required reciprocating motion of an intermittent or irregular character.

Camaieu. (1) The same as CAMEO (*q.v.*) (2) A painting or engraving in monotone.

Camail (*Armour, etc.*) (1) The chain mail armour attached to the bascinet helmet, worn during the fourteenth and fifteenth centuries. It protected the sides of the head and the neck, and covered the shoulders like a tippet. (2) A headdress which was worn by priests in winter.

Camber (*Build.*) The extent to which a horizontal beam is curved upwards in the centre. For cast iron, $\frac{3}{4}$ in.; wrought iron and steel, $\frac{1}{2}$ in. to every 10 ft. of span. Also a general expression for the amount of curvature of an arch, etc.

Camber Arch (*Architect.*) An arch rising $\frac{1}{8}$ in. to every foot of span, and straight on the top. In some cases the curvature is entirely omitted; the separate voussoirs then form a straight structure which serves instead of a single large stone or beam.

Cambered (*Carp., Build., etc.*) Raised in the centre: slightly curved or arched.

Camber Slip (*Build.*) A mould or template (*q.v.*) used for cutting a camber arch.

Cambium (*Botany*). The layer of living formative tissue lying between the wood and soft bast of a vascular bundle in a Dicotyledon. The layer which gives rise to the cork is termed CORK CAMBIUM or PHELLOGEN.

Cambrian System (*Geol.*) A group of ancient rocks, chiefly consisting of marine sediments, which were formed after the close of Archæan times and before the Ordovician period. The lowest beds are usually characterised by TRILOBITES (*q.v.*), allied to *Olenellus*, the middle by *Paradoxides*, the upper by *Olenus*. These rocks are of great interest as showing examples of each group of invertebrate animals, even though they lie at or near the base of those which yield traces of life.

Cambric. A fine light plain-texture linen material, more closely woven than lawn, and chiefly used for handkerchiefs. Originally made at Cambray in Flanders.

Cambro-Silurian Rocks. A name applied by Jukes to the rocks now called ORDOVICIAN (*q.v.*), which lie between the true Cambrian Rocks and those of Silurian age, and whose included fossils differ materially from those of the formations above and below.

Camel Hair. This material is used for artists' brushes. It is also a trade name for a kind of yarn composed of wool and hair, used in the weaving of driving belts (*q.v.*)

—— (*Woollen Manufac.*) The sorted hair of the camel usable in the manufacture of yarn for weaving purposes.

Cameo. Usually a design in relief, produced by cutting to various depths into a substance which consists of thin laminæ of different colours. It is generally a shell (one of the *Gasteropods*), but onyx is used also.

Caméoid (*Dec.*) A popular relief decoration for walls and ceilings, made by moulding paper materials.

Camera (*Music*). Secular, as distinguished from CHIESA, sacred. *Concerto di camera* was for performance in a room; *Concerto di chiesa* for performance in church.

Camera Lucida. An optical device by which a virtual image (*q.v.*) of an object (which may be a microscope slide, etc.) is seen on a sheet of white paper placed underneath the instrument; the image is usually viewed with one eye, so that a pencil can be used at the same time to make a drawing of the object. The optical effect is usually produced by a prism which causes total internal reflection of the rays proceeding from the object. When used for drawing an object under the microscope, the prism is fixed at, or above, the top of the tube, with its axis at right angles to the axis of the microscope.

Camera Obscura. This consists of a convex lens fixed in an aperture in the centre of the wall, or in the roof, of a small room from which light is excluded, an image of scenery outside being thrown by the lens on the opposite wall or on to a table standing beneath the lens. The camera obscura is merely an optical toy or curiosity, on the principle of the ordinary photographic camera.

Camera, Photographic. *See* PHOTOGRAPHIC CAMERA.

Cameron's Sewage System. *See* SEPTIC TANK SYSTEM.

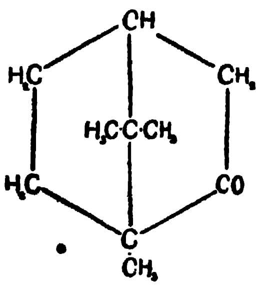
Campaign (*Met.*) The period during which the lining of a blast furnace can last.

Campanes (*Her.*) Bells suspended to charges.

Campaniform Capital (*Architect.*) One of the types of capitals used by the Egyptians. Its form resembles that of an inverted bell or a fully developed lotus flower. *See* HATHOR HEADED, CLUSTERED LOTUS, LOTUS, *and* PALM CAPITALS.

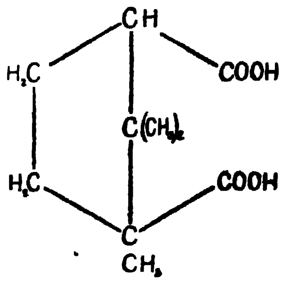
Campanile (*Architect.*) A tower erected for the use of bells. The term is applied especially to the detached towers built for this purpose in Italy. A notable instance was the Campanile of St. Mark's, Venice, now being rebuilt.

Camphor (Common *or* Japan Camphor). A colourless translucent crystalline solid; characteristic smell; melts at 175°; volatilises even at ordinary temperatures; sp. gr. ·99; soluble 1 in 700 water; readily soluble in oils, alcohol, etc. Alcoholic solution is dextrorotatory (*q.v.*) Used in medicine. It is obtained by distilling wood of camphor tree with steam, pressing and subliming distillate; also by oxidising BORNEO CAMPHOR with nitric acid.



CAMPHOR.

Yields CYMENE (*q.v.*) when distilled with phosphorus pentoxide; boiled with iodine, yields CARVACROL (*q.v.*); reduction converts it into Borneo camphor; oxidation yields chiefly CAMPHORIC ACID, an optically active dibasic acid. ARTIFICIAL CAMPHOR (so-called) is PINENE HYDROCHLORIDE, $C_{10}H_{17}Cl$; made by passing hydrochloric acid gas into well cooled pinene (*q.v.*) It is a white crystalline mass with an odour like that of camphor; melts at 125°. BORNEO CAMPHOR (BORNEOL) is related to camphor as shown in the formulæ:



CAMPHORIC ACID.

$$C_8H_{14}\left\langle\begin{matrix}CO\\ |\\ CH_2\end{matrix}\right. \qquad C_8H_{14}\left\langle\begin{matrix}CHOH\\ |\\ CH_2\end{matrix}\right.$$

Camphor. Borneol.

Its chief source is a tree, *Cinnamomum camphora* (order, *Lauraceæ*), growing in Borneo and Sumatra. It is a white solid melting at 203°, and smelling of camphor and peppermint. Can be converted into and obtained from common camphor. *See* above.

Camptonite (*Geol.*) A name given to one of the numerous varieties of MICA TRAP (*q.v.*), which in this case has affinities with the DIORITES (*q.v.*) It has a microgranitic ground mass, and contains plagioclase and hornblende (*q.v.*) Much of what used to be called Camptonite would now be comprehended under the useful general term PORPHYRITE.

Camwood. *See* DYES AND DYEING.

Canada Balsam. A transparent resinous fluid, very viscous, and hardening into a clear transparent solid, whose refractive index is about equal to that of glass, 1·53. It is obtained from the Balsam Fir of North America, *Abies balsamea* (*Coniferæ*). It is much used in optics for cementing lenses together, mounting microscopic objects, etc.

Canal (*Biology*). A hollow cavity or channel for the passage of a liquid or a gas through the tissues of an organism.

—— (*Civil Eng.*) An artificial waterway with LOCKS (*q.v.*) for crossing raised ground, and a supply of water at its highest levels to compensate for water allowed to escape from the locks.

Canary Grass. *Phalaris canariensis* (order, *Gramineæ*). The grass is extensively grown in England, and also imported from other countries. The seed is used for cage birds.

Canary Wood. *See* WOODS.

Cancels (*Typog.*) Pages that have been reprinted owing to an error, literary or technical. Usually indicated by an asterisk at the foot of the page.

Cancer, Tropic of (*Astron.*) *See* TROPICS.

Candelabrum. A candlestick, generally an ornamental one. A branched candlestick holding a number of candles.

Candle. Formerly candles were made from tallow by repeatedly dipping the wicks, suspended from a frame, into a tank of tallow kept in a liquid state by heat. Tallow candles are still made, principally for use in mines and in workshops, a coloured thread being often introduced into the wick to distinguish the works in which they are used and to prevent pilfering. Candles are now usually made from stearin or paraffin wax (*q.v.*), or a mixture of both, by moulding in special frames or machines. Sometimes small quantities of ozokerite (*q.v.*), ceresine, and other waxes are employed. Candlemaking machines are mostly arranged in such a manner that a continuous supply of candles is produced. The wicks are run off from bobbins, passed through orifices, and are held exactly in the centre of a series of hollow cylinders equal in diameter to the candle. The molten wax enters the moulds, cold water is then admitted into the space surrounding the moulds, and quickly cools the wax, and the candle is formed. The candles are raised out of the moulds by means of a lever, the wicks following ready for the next moulding. Some machines make a conical cap or end to the candle to hold it more firmly in the candlestick. The wicks are usually plaited, and are treated with a solution of borax and sulphate of ammonia, which causes them to burn without guttering or leaving an ash. Candles are now made in a large variety of shapes and sizes, special mixtures of waxes being employed for those intended to be used in hot climates. As illuminants candles occupy the lowest place, on account of the impurity they add to the air during combustion. A candle of standard size yields on combustion nearly half a cubic foot of carbon dioxide and water. *See also* ARTIFICIAL ILLUMINATION.

Candle Flame. *See* FLAME.

Candle, Standard. *See* STANDARD CANDLE.

Cane (*Botany*). *Calamus*—various species (order, *Palmæ*). Under the name of cane the stripped stems of various slender palms are imported for making chair bottoms, baskets, etc. The term RATTAN CANE is also employed.

—— (*Silk Manufac.*) *See* WARP.

Canephorus, Canephora. In ancient Grecian festivals one of the maidens who carried on their heads the implements of sacrifice, etc.

Cane Sugar (*Chem.*), $C_{12}H_{22}O_{11}$ (*Saccharose*). Occurs in juice of sugar cane (20 per cent.), of the beet (10 to 20 per cent.), of the maple and other plants. To obtain the sugar the juice is extracted from the cane or beet by a process of diffusion. It is then treated with milk of lime to separate albumins and neutralise acid; with sulphur dioxide to prevent fermentation; and then decolourised by filtration through animal charcoal. After concentration it is evaporated in vacuum pans (*q.v.*) till it deposits, on cooling, sugar crystals termed RAW SUGAR. The raw sugar is refined by what is practically a repetition

of the above treatment of the juice. Sugar may be obtained from the molasses by a process of diffusion or by adding strontia (SrO), which forms a solid with the sugar of the molasses, insoluble in cold water. This solid ($C_{12}H_{22}O_{11}SrO$) is filtered, washed, pressed, suspended in water, and decomposed by carbon dioxide, giving insoluble strontium carbonate and a solution of sugar which can then be crystallised. Sugar is a white crystalline solid soluble at the ordinary temperature in $\frac{1}{3}$ part water; its solution is dextrorotatory (*q.v.*) Sugar melts at 160°; allowed to solidify, it forms barley sugar. Heated above its melting point it loses water, and about 200° forms a brown substance called CARAMEL, which is an indefinite mixture of compounds soluble in water, precipitated by alcohol, much used in colouring sweets, soups, etc. Cane sugar has no reducing properties (*cf.* MALTOSE *and* LACTOSE). Dilute acids "invert" it—*i.e.* change it to a mixture of DEXTROSE and LAEVULOSE (*q.v.*) by addition of water, $C_{12}H_{22}O_{11} + H_2O = C_6H_{12}O_6 + C_6H_{12}O_6$. This mixture is lævo-rotatory, hence the term "inversion." Yeast first inverts cane sugar and then ferments the dextrose and lævulose, forming chiefly alcohol and carbon dioxide. Cane sugar yields an acetate with acetic anhydride; a nitrate with nitric acid. Heated with excess of nitric acid, it gives oxalic acid.

Cannel Coal. *See* COAL.

Cannets (*Her.*) Ducks without feet or beaks.

Cannon (*Eng.*) In engineering, a hollow shaft through which passes another shaft, which has some motion independent of that of the cannon.

Cannon Pinion (*Watchmaking*). The pinion to which the minute hand of a watch is fixed.

Canon (*Art, Science, etc.*) Denotes rule or law. It is applied to any art or science that is governed by fixed laws. The laws of the Church are called CANONS.

—— (*Music*). A composition in which the strictest imitation of the opening passage or pattern is maintained at various intervals, and may be in two, three, four, or any greater number of parts. In some cases all the voices take part in Canon, as in the well known grace, Byrd's "Non nobis Domine"; in other cases only a part of the voices are in Canon, whilst the accompanying parts are free, as in Tallis's Hymn-Canon "Glory to Thee, my God." The study of Canon is especially useful to the student for Fugal writing. Canons are "infinite" when they lead back to the beginning, and "finite" when ending either naturally or by means of a Coda.

—— (*Typog.*) One of the largest kinds of type. *See* TYPE.

Canopic Vase *or* **Canopus** (*Archæol.*) A vase used by the Egyptians for preserving the viscera of the dead.

Canopy (*Architect., etc.*) An ornamental roof or covering over niches, etc., used in Gothic architecture. A covering or hanging suspended over a person or object. *See* BALDACHINO *and* TABERNACLE.

Cant (*Carp., etc.*) (1) An obtuse angle. (2) A slope, tilt, or inclination.

Cantabile, Cantando (*Music*). In a singing manner.

Cant Brick (*Build.*) A brick cut on the splay—*i.e.* at any angle other than a right angle.

Cantharides (*Zool.*) *Cantharis vesicatoria* (order, *Coleoptera*). The dried beetle ("Spanish blister fly") is used in medicine as a blistering agent.

Cantharus (*Pot.*) A Grecian two-handled drinking vessel varying in form and dimensions. Bacchus, the god of wine, generally is represented with one.

Cantilever (*Civil Eng.*) A projecting beam or girder, supported at one end only; it is usually built into a wall or other structure.

Cantilever Bridge (*Civil Eng.*) A bridge constructed of two or more CANTILEVERS (*q.v.*), which meet in the centre of the span, but do not depend on each other for support. The Forth Bridge, Edinburgh, is the finest example of a cantilever bridge in the world.

Canting (*Eng.*) Tilting or causing a slope.

Canting Arms (*Her.*) Allusive armorial bearings; also called a REBUS.

Canto Fermo (*Music*). Fixed song or melody; that melody to which other melodies are added in counterpoint.

Canton (*Her.*) A division of the shield, and one of the honourable ordinaries. It is placed in a corner of the shield, and its size is one-third of the chief.

Cantoned (*Architect.*) A term applied to a building or pier which has its angles emphasised by means of pilasters, columns, or rustic work.

—— (*Her.*) A saltire, or cross, placed between four charges is said to be cantoned. It also denotes a single charge placed in the first quarter of the shield.

Canton's Phosphorus (*Chem.*) *See* CALCIUM SULPHIDE, *under* CALCIUM COMPOUNDS.

Cantoris (*Music*). That side of a choir on which the cantor, or chanter, sits. The opposite side to DECANI. It is the left side, looking east.

Canvas Wall Hangings (*Dec.*) A plain canvas material having a specially prepared surface formed by rolling the fabric, and an adhesive backing to facilitate hanging on walls. BURLAP, CRASH, and FABRIKONA are the best known varieties. Made in various colours, and often used with a stencilled frieze done in bright colours upon the fabric.

Caoutchouc. The South American name for the coagulated milky sap of several plants of tropical origin belonging to the order *Euphorbiaceæ*. There are over fifty varieties of Caoutchouc which may be roughly classed in order of importance as African, South and Central American, Asiatic and Oceanic. It is an elastic gummy tenacious substance. Being impervious to the action of water and atmosphere, and largely so to acids and alkalis, it is used in many arts and manufactures. Originally used for erasing pencil marks, it is now very extensively employed industrially. The material is obtained by cutting incisions in the trunk and collecting the juice; it is dried by careful exposure in thin layers to the heat of a smoky flame. When pure it has the formula $(C_5H_8)x$; on distillation it yields ISOPRENE, C_5H_8; undergoes oxidation on exposure to moist air in presence of light; heated above 120° it softens, and does not again become hard. It is soluble in benzene and its homologues toluene and xylene, in turpentine, petroleum spirit, carbon disulphide, chloroform, etc. Treated with chloride of sulphur or with certain metallic sulphides and sulphur (*e.g.* antimony penta-sulphide, Sb_2S_5), part of its hydrogen is replaced by sulphur, and the product is VULCANISED RUBBER. Vulcanised rubber deteriorates from slow oxidation, the rubber becoming brittle, owing to formation of resinous substances. *See* RUBBER.

Cap (*Bind.*) An envelope of paper to protect the edges of a book while being bound.

—— (*Build.*) The coping stone on the top of a shaft or pier. *See also* CAPITAL.

—— (*Carp. and Join.*) The turned end of a handrail that is fixed on top of a NEWEL (*q.v.*)

—— (*Eng.*) A general term in engineering for a cover, or the loose upper part of an object—*e.g.* the upper part of a plummer block or shaft bearing, which holds the brasses in position.

—— (*Gasfitting, etc.*) A tubular cover with a female thread to stop the end of a gas or water pipe.

—— (*Mining*). Rock, covering the ore in a vein.

Capacity, Electrical. The quantity of electricity required to charge a conductor up to unit potential (*q.v.*); or, in other words, the ratio of the charge on a conductor to its potential.

Cap-à-Pie (*Arm., Her.*) Completely armed, from head to foot.

Caparison (*Arm., etc.*) (1) The defensive armour which was used for horses. (2) An ornamented cloth for covering a saddle: also the housings or trappings covering a horse, especially on State occasions.

Capers (*Botany*). The capers of commerce are the flower buds of *Capparis spinosa* (order, *Capparidaceæ*). The plant grows in Southern Europe.

Capillarity. The surface of a liquid behaves as if it consisted of a thin film, capable of being stretched to an infinite extent, but always exerting the same tensile force across each centimetre. This force is called SURFACE TENSION: its value varies with different liquids: for water it is 81 dynes per centimetre, if the water is clean and in contact with air. If a solid which is not wetted by any given liquid is laid upon it, the existence of this film becomes apparent; for example, a piece of iron laid upon mercury shows clearly the kind of hollow which would be produced by an object lying on a slightly stretched membrane, and the same thing can even be seen if a needle with a slightly greasy surface be laid upon water, when it will remain held up above the surface, which can be seen to curve down under it. If a tube be pushed down into a liquid, one of two things will occur. If the liquid does not wet the tube, as in the case of a glass tube plunged into mercury, the level of the liquid inside will be lower than the level outside. This is termed CAPILLARY DEPRESSION. The greater the diameter of the tube, the less the depression. This is much the same result as would obtain if we pressed a similar tube down on a stretched elastic membrane. The analogy, however, is not completely true, as the hydrostatic pressure of the liquid has to be taken into account. The effect of this is shown in fig. 1. A is the level of the liquid outside the tube and B the level inside. At the level B there is a hydrostatic pressure upward, due to the column of liquid of height AB. In the absence of any tension of the film on the surface the liquid at B would rise to the height A, and become equal inside and outside. But as the tension is present, the liquid inside rises to such a height that the upward pressure is just balanced by the downward force due to the tension of the surface. In fig. 2 is shown the case of a tube immersed in a liquid which wets its surface. In this case the liquid tries to spread itself out over the greatest possible amount of surface of the tube, and this results in an upward force at AA, which draws a column of liquid of height AB up the tube. The upward force due to surface tension is exactly counter-balanced by the downward force due to the weight of a column of liquid AB. If r is the radius of the tube, then its circumference is $2\pi r$; if T represent the tension across 1 cm., then the total tension at AA is $2\pi r\mathrm{T}$, as it exists right round the circumference of the tube. The weight of the liquid column is equal to its volume multiplied by its density—that is, $\pi r^2 h\rho g$. We thus get the following equation:

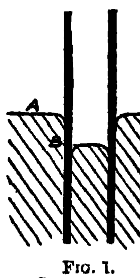


FIG. 1.
CAPILLARITY.

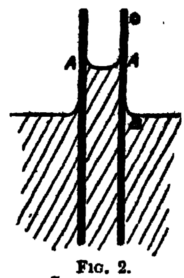

FIG. 2.
CAPILLARITY.

$$2\pi r\mathrm{T} = \pi r^2 h\rho g$$

therefore
$$\mathrm{T} = \frac{\pi r^2 h\rho g}{2\pi r} = \tfrac{1}{2} r h\rho g$$

From this we can calculate the amount of the surface tension, as all the quantities on the right hand side are easily observed. It is also evident from the equation that the product rh is constant; therefore the diameter of the tube and the height of the column are in inverse proportion—*i.e.* the narrower the tube the higher the column of liquid which rises in it.

Capillary (*Zoology*). Minute thin-walled blood-vessels which ramify in great numbers through the tissues.

Capillary Electrometer (*Elect.*) A form of electrometer (*q.v.*) depending on an alteration produced by a change in potential in the surface tension between mercury and dilute sulphuric acid. It is chiefly of scientific interest, and is rarely used in practice.

Capital (*Architect.*) The uppermost member of a column or pilaster between the shaft and the feature supported. When one feature crowns another the former is sometimes referred to as the capital of the latter. *e.g.* Capital of Guttæ (*q.v.*) *See* ARCHITECTURE, ORDERS OF: COLUMN: DORIC, *etc.*

Capital Letters (*Typog.*) *See* CAPS.

Capital of Guttæ (*Architect.*) The fillet between the guttæ and the tenia in a Doric entablature. The depth of this fillet is much smaller in Roman than in Greek examples. *See* GUTTÆ: TRIGLYPH: ARCHITECTURE, ORDERS OF, *and* ENTABLATURE.

Capital of Triglyph (*Architect.*) The fillet immediately above and projecting over the triglyph in a Doric frieze. The projection of the capital beyond the triglyph is smaller in Greek than in Roman examples. *See* TRIGLYPH: ARCHITECTURE, ORDERS OF, *and* ENTABLATURE.

Capitulum (*Botany*). A compact form of inflorescence simulating a single flower. The "head" consists of a shortened axis (flat, convex, or concave) bearing many stalkless flowers (florets). The capitulum is invested by a number of scaly bracts.

Cap of Maintenance *or* **Dignity** (*Cost.*) A cap borne before the sovereigns of England at their coronation as one of the insignia of office. Such a cap is also borne before the mayors of certain cities.

Cap of Maintenance *or* **Dignity** (*Her.*) A cap used instead of a wreath to place a crest upon. Sometimes borne as a charge.

Cappagh-Brown (*Dec.*) Manganese brown: a pigment manufactured from bituminous earth, coloured by oxide of manganese and iron.

Capping (*Carp. and Join.*) The moulding on the top edge of a screen, the strings of stairs, etc.

—— (*Eng.*) The SHROUDING (*q.v.*) of gearing.

Capriccioso (*Music*). In a capricious manner.

Caprices (*Art*). Drawings or engravings, extravagant and fanciful in composition, such as those of Goya.

Capricorn, Tropic of. *See* TROPICS.

Caproic Acid (*Chem.*) $CH_3.(CH_2)_4.COOH$. A liquid boiling at 205°; it occurs combined with glycerine in butter; is a decomposition product of albumin; its amide is LEUCINE (*q.v.*)

Caps (*Typog.*) An abbreviation of the word "Capitals," usually indicated by three lines beneath the letters to be so printed, thus ≡. Small caps are indicated by two lines =.

Capsicum (*Botany*). *Capsicum minimum* (order, *Solanaceæ*). The dried ripe fruits form the well-known CHILLIES, and when ground form CAYENNE PEPPER.

Cap Spinning (*Woollen Manufac.*) In the cap spinning frame each spindle is mounted with a metal cap, and the threads whirl round the rim as they pass on to the bobbin.

Capstan (*Eng.*) A vertical rotating cylinder on which a rope is wound. The name often includes the machinery or engine by which the capstan is driven, as in the steam capstan of modern ships.

Capstan Headed Screw (*Eng.*) A screw with a large head, through which are drilled transverse holes, into which a small lever, or "tommy," is inserted to turn the screw.

Capstan Lathe (*Eng.*) A lathe with a rotating tool holder on the slide rest, by which various tools can be brought into action on the work in succession. It is also termed a TURRET LATHE.

Capsule (*Botany*). A class of fruit that opens by means of valves, pores, or slits to set free the numerous seeds.

Caraguata Fibre (*Botany*). *Eryngium pandanifolium* (order, *Umbelliferæ*). A fibre from the leaves is used under the trade name of Caraguata.

Caramel. *See* CANE SUGAR.

Carapace. The hard outer shell or exo-skeleton of certain animals; *e.g.* the shell of the tortoise.

Carat. (1) The standard of weight used by jewellers in weighing diamonds and other precious stones. It is equal to about $\frac{1}{150}$ of an ounce troy, or $3\frac{1}{6}$ grains. It is divided into 4 "carat grains." (2) The standard of fineness of gold. Pure gold is said to be "24 carat." STANDARD GOLD is "22 carat"—*i.e.* 24 parts by weight of the alloy contain 22 parts of pure gold. Similarly, 18 carat gold contains 18 parts of gold out of 24 parts by weight of the alloy, and so on for 15 carat, 12 carat, etc.

Caraway (*Botany*). *Carum carui* (order, *Umbelliferæ*). The so-called "seeds" are the mericarps (*q.v.*) or half fruits; they yield on distillation oil of caraway.

Carbamide (*Chem.*) The systematic name for UREA (*q.v.*); the name arises from urea being the diamide of carbonic acid.

$$OC\begin{matrix} \diagup OH \\ \diagdown OH \end{matrix} \qquad\qquad OC\begin{matrix} \diagup NH_2 \\ \diagdown NH_2 \end{matrix}$$

Carbonic acid. Carbamide.

Carbazole (*Chem.*) $\begin{matrix} C_6H_4 <> C_6H_4 \\ (1:2)\ NH\ (1:2) \end{matrix}$

Occurs in coal tar, and thus in crude anthracene; forms colourless plates, melting at 238°; readily sublimes. Is a feeble base like pyrrol, and also gives the pine-shaving reaction (*q.v.*). Nitric or nitrous acids give a blue colour to its solution in sulphuric acid.

Carbazotic Acid (*Chem.*) PICRIC ACID (*q.v.*)

Carbides (*Chem.*) Compounds formed by the union of carbon and a metal, directly or indirectly. Some of the important carbides are CALCIUM CARBIDE, CaC_2, obtained pure in golden yellow opaque crystals by heating pure lime and sugar charcoal in the electric furnace. The crude product is obtained from limestone and coal or coke. With water it gives acetylene (*q.v.*) Barium and strontium form similar compounds. ALUMINIUM CARBIDE, C_3Al_4: yellow transparent crystals obtained by heating carbon and aluminium, or calcium carbide and aluminium, in the electric furnace; it is decomposed by water, giving methane, CH_4. IRON CARBIDE, Fe_3C, has been obtained by electrolysis from steel; also in brilliant white crystals from Swedish iron by heating in a carbon crucible in the electric furnace, and subsequent purification of the product. Its formation and decomposition probably play an important part in the tempering of steel.

Carbine *or* **Carabine** (*Arms*). A firearm which came into use in the si[illegible]th century. It had a wheel-lock, and wide bor[illegible] was shorter than the ordinary hand gun. Generally used by cavalry.

Carbinol (*Chem.*) A name given to methyl alcohol in a system of nomenclature which names more complex alcohols as derivatives of methyl alcohol, the simplest possible alcohol. Thus, $\begin{array}{c} H \\ | \\ H—C—OH \\ \\ H \end{array}$ is methyl alcohol, and $\begin{array}{c} H \\ \\ CH_3—C—OH \\ | \\ C_2H_5 \end{array}$ would be called methyl ethyl carbinol.

Carbohydrates (*Chem.*) The carbohydrates are naturally occurring compounds containing six or a multiple of six carbon atoms, combined with hydrogen and oxygen, the proportions of these last two elements being the same as in water. Carbohydrates containing six carbon atoms are called MONOSES or MONOSACCHARIDES—examples are dextrose, lævulose, galactose; those containing twelve carbon atoms are called BIOSES or DISACCHARIDES—examples are cane sugar, lactose, maltose; those containing $(C_6)n$ are called POLYOSES or POLYSACCHARIDES—examples are starch and cellulose. The functions of carbohydrates in the animal system are the production of heat and energy. They are also a source of fat.

Carbolic Acid *or* **Phenol.** A powerful antiseptic, obtained from coal tar by distillation. It constitutes a great part of the tarry fluids on the market which are used for disinfecting purposes. The "carbolic

acid" powders and soaps are preparations containing the acid. Great care is necessary when using the acid, owing to it being so violent a poison. In chemical language it is termed PHENOL (*q.v.*)

Carbon (*Chem.*), C. Atomic weight, 12. An element met with in three allotropic forms—*viz.* DIAMOND (*q.v.*), GRAPHITE (*q.v.*), AMORPHOUS CARBON. CHARCOAL is one form of amorphous carbon, but it is not pure carbon; it contains ash and occluded gases. LAMP BLACK is another impure form, containing oil. Bone black or animal charcoal is another impure form (*see* BONE BLACK). Coke is another form containing the ash of the coal from which it was made. Pure amorphous carbon can be obtained by heating cane sugar out of air, then passing chlorine over the strongly heated residue, and allowing to cool in as good a vacuum as possible. The amorphous forms of carbon absorb gases, and take up colouring matter from many coloured solutions; they are powerful reducing agents—hence the use of coke in many metallurgical operations. Carbon is insoluble in all solvents, and is infusible; at the temperature of the electric arc the amorphous forms pass into graphite.

Carbonaceous Rocks (*Geol.*) Strata into whose composition carbonaceous matter of any kind enters. Besides the numerous varieties of coal may be mentioned OIL SHALE, BLACK BAND IRONSTONE, and even GRAPHITE SCHIST.

Carbonado (*Min.*) A very hard native form of carbon from Brazil. It is as hard as diamond. Used for truing-up emery wheels.

Carbonates (*Chem.*) The salts of carbonic acid. *See* CARBON DIOXI[illegible] As carbonic acid is dibasic, it gives rise to two [illegible]es of salts—the normal and acid carbonates (also called BICARBONATES) Thus:

$$\mathrm{O = C}\left\langle\begin{matrix}\mathrm{ON}\\ \mathrm{ONa}\end{matrix}\right. = \mathrm{Na_2CO_3}, \text{ normal sodium carbonate;}$$

$$\mathrm{O = C}\left\langle\begin{matrix}\mathrm{OH}\\ \mathrm{ONa}\end{matrix}\right. = \mathrm{NaHCO} \quad \text{acid sodium carbonate or sodium bicarbonate.}$$

The carbonates of sodium, potassium, and ammonium are soluble in water; the other normal carbonates are insoluble in water. Acid carbonates are soluble in water. Sodium and potassium normal carbonates are not decomposed on heating; they melt. Barium carbonate is decomposed with difficulty by heat; the remaining carbonates more or less readily. Many carbonates occur naturally. *See* CHALK, MARBLE, WITHERITE, STRONTIANITE, SPATHIC IRON ORE, CERUSSITE, CALAMINE, DOLOMITE, MAGNESITE, RHODOCROSITE, *etc.*

Carbon Black (*also called* **Gas Black**). A valuable series of pigments made principally from natural gas at Pittsburg and elsewhere in the United States. They are very fine, intensely black, and are used largely in the manufacture of printing inks, paints, etc.

Carbon Cores (*Moulding*). Cores (*q.v.*) of carbon are sometimes used in a mould where very heavy pressures are produced by the fluid metal during casting.

Carbon Dioxide *or* **Carbonic Acid Gas** (*Chem.*) CO_2. A colourless heavy gas having slight smell: water dissolves its own volume of the gas at ordinary temperature and pressure. Only substances with an extremely powerful affinity for oxygen, such as potassium and magnesium, can burn in the gas; for similar reasons, though it contains nearly 73 per cent. of oxygen, animals are asphyxiated in it. It is liquefied at the ordinary temperature under a pressure of 53 atmospheres, and liquid carbon dioxide is now used in icemaking, aërated water manufacture, etc. The gas is a product of combustion and respiration (*see* ATMOSPHERE), also of processes of fermentation and decay. It may be obtained by the action of an acid on a carbonate—*e.g.* hydrochloric acid and marble. When carbon dioxide is dissolved in water, part of the gas combines with the water to form the weak and unstable acid, carbonic acid, $\mathrm{O=C=O + H_2O = O=C}\left\langle\begin{matrix}\mathrm{OH}\\ \mathrm{OH}\end{matrix}\right.$. ORTHOCARBONIC ACID would have the formula $C(OH)_4$; it has not been prepared, but its organic salts are known—*e.g.* ethyl orthocarbonate, $C(OC_2H_5)_4$.

Carbon Dioxide in Air (*Hygiene*). The amount of this gas present in air averages about 4 parts in 10,000 parts of air. Its presence is due to respiration, artificial illumination, combustion, and manufacturing processes. Every individual exhales, while at rest, 0·6 of a cubic foot per hour. This amount increases from 0·9 during light work to 1·8 of a cubic foot during hard work. It is found that there is always a constant ratio between the quantity of carbon dioxide and other impurities present in the air. In estimating the purity of air, the amount of carbon dioxide is determined, since it furnishes a convenient index of general contamination. The action of plants on this gas is interesting. Every plant which contains chlorophyll has the power, under the influence of sunlight, of splitting up the gas into its component parts—namely, carbon and oxygen. The plant retains the carbon for its own use in tissue building, and liberates the oxygen.

Carbon Disulphide *or* **Bisulphide** (*Chem.*), CS_2. A colourless highly refracting liquid, having pleasant smell when perfectly pure, but ordinarily smelling like rotten cabbages. Boils at 46°; its vapour is very inflammable; insoluble in water. Largely used as a solvent for many organic substances, such as fats, oils, indiarubber, etc.; also readily dissolves sulphur and iodine. It is prepared by passing the vapour of sulphur over strongly heated carbon. It is the sulphur analogue of carbon dioxide; with alkalis it forms sulphocarbonates, R_2CS_3, analogous to the carbonates R_2CO_3.

Carbon Filters. *See* ANIMAL CHARCOAL.

Carbonic Acid. *See* CARBON DIOXIDE.

Carbonic Oxide. CARBON MONOXIDE (*q.v.*)

Carboniferous Rocks. *See* COAL.

Carboniferous System (*Geol.*) The group of strata which succeeds the Upper Old Red Sandstone (or its chronological equivalent) and lies beneath the base of the Lower New Red. It is so called because in Britain it affords coal seams of commercial value. It is primarily divided into an Upper and Lower subdivision, in both of which occur workable coals. Along with the Devonian Rocks and their equivalent, the Old Red Sandstones, it constitutes the DEUTEROZOIC ROCKS.

Carbon in Food (*Hygiene*). It is calculated that while doing a moderate day's work a man will eliminate from the lungs, as carbon dioxide, from 240 to 290 grammes of carbon. Other waste products, such as nitrogen, etc., are also eliminated from the body. To replace this loss, it is necessary to arrange a proper dietary. The proportion of carbon to nitrogen should be 16 to 1. *See also* FOODS, *under* SANITATION.

Carbonisation *or* **Carburisation** (1) The amount of carbon present in iron. It varies from a mere trace to very considerable amounts. *See* IRON, STEEL, *etc.* (2) The destructive distillation of organic matter (*e.g.* coal in gas manufacture).

Carbon Monoxide *or* **Carbonic Oxide** (*Chem.*), CO. A colourless gas having the same density as nitrogen; very slightly soluble in water. It is intensely poisonous, and, having no smell, is therefore a dangerous gas. It owes its poisonous action to its power of forming a more stable compound than oxygen does with the hæmoglobin of the blood, and thus causing asphyxia. It burns in oxygen with a blue flame, forming carbon dioxide. It is a reducing agent (*q.v.*) Unites with some metals, *e.g.* finely divided nickel, on heating, to form carbonyls, *e.g.* nickel carbonyl, $Ni(CO)_4$. It is produced whenever carbon is burnt in a restricted supply of oxygen; also on heating formic acid with sulphuric acid: oxalic acid with sulphuric acid (in this case equal volumes of this gas and carbon dioxide): potassium ferrocyanide with sulphuric acid. It may often be seen burning at the top of a bright fire, being formed from carbon dioxide produced during the combustion by union of the heated carbon dioxide and carbon, $CO_2 + C = 2CO$. The presence of 0.5 per cent. of this gas in air which is being inhaled produces poisonous symptoms, and 1 per cent. is rapidly fatal. Carbonic oxide is one of the constituents of coal gas (from 5·5 to 7 per cent.), and would therefore find its way into the air during leakage. Water gas (*q.v.*) also contains a large proportion of carbonic oxide, and as it has little or no smell, the use of water gas requires the exercise of great vigilance in preventing leakage, which is much less readily detected than in the case of coal gas.

Carbon Oxychloride (*Chem.*) *See* CARBONYL CHLORIDE.

Carbon Printing (*Photo.*) Paper is coated with gelatine containing potassium dichromate. When acted on by light, this becomes insoluble; while parts unacted on remain soluble, and may be washed away. By impregnating the gelatine with some suitable colouring matter a very fine permanent print can be made.

Carbonyl (*Chem.*) This name is given to the group $-CO-$ when in combination.

Carbonyl Chloride, Phosgene Gas, *or* **Carbon Oxychloride** (*Chem.*) A pungent-smelling gas easily condensed to a liquid boiling at 8°. It is obtained by union of equal volumes of carbon monoxide and chlorine in sunlight, and by oxidation of chloroform (*q.v.*) It is decomposed by water, $COCl_2 + H_2O = CO_2 + 2HCl$. Used as a reagent in organic chemistry. Thus with ammonia it gives urea; with zinc alkyls it gives ketones (*q.v.*); with benzene and aluminium chloride it gives diphenylketone. The graphic formula is $OC\!\!<^{Cl}_{Cl}$.

Carborundum. A Silicide of Carbon, SiC, used as an abrasive, harder than emery (which it resembles). Used also as an infusible coating for furnaces, etc. First manufactured by Acheson, at Niagara.

Carboxylic Acids (*Chem.*) The presence of the group carboxyl, $-C\!\!<^{O}_{OH}$, in an organic compound confers acid properties upon the compound; hence compounds containing this group are called carboxylic acids. Organic acids are known which do not contain this group, *e.g.* uric acid, picric acid.

Carbuncle (*Min.*) Red Garnet cut *en cabochon*. *See* CABOCHON.

Carburetter (*Motor Cars, Oil Engines*). The apparatus for turning oil into gas in petrol or other oil engines. The two main forms are SPRAY and SURFACE Carburetters. In the former a fine jet of oil is sprayed into a hot chamber, the supply being governed by a needle valve actuated by a hollow float, which rises and closes the valve when the supply of oil is too great. In surface carburetters a current of air is caused to bubble through the oil in a tank, producing evaporation at the surface of the oil and causing a mixture of air and explosive vapour to collect in the upper part of the tank. In both forms a further regulated supply of air can be caused to mix with the vapour produced in the carburetter, in order to obtain the explosive mixture which produces the greatest effect in the cylinder.

Carbylamines. Another name for the ISOCYANIDES (*q.v.*)

Carcanet (*Cost.*) A collar or necklace usually set with jewels.

Carcass (*Carp. and Join.*) (1) The structural part of a building—*i.e.* walls, naked floors, partitions, and roof. (2) The shell or outer part of any piece of joiner's or cabinetmaker's work.

Carchesium (*Pot.*) A beaker or cup used by the Greeks. It was slightly contracted in the middle, and had two handles extending from the base to the rim.

Cardamoms (*Bot.*) *Elettaria cardamomum* (order, *Zingiberaceæ*). The dried seeds are used in pharmacy and as a condiment.

Card Clothing (*Cotton Spinning*). A general term applied to the wire filleting on the cylinders, doffers, flats, or rollers of a carding engine. There are several gauges to suit Indian, American, or Egyptian cotton.

—— (*Woollen Manufac.*) Strips of leather or other suitable foundation into which wire teeth are inserted. The fineness of clothing—*i.e.* number of points per square inch—varies according to the position of the roller to which it is nailed in the carding machine, increasing towards the delivery end.

Carded Yarns (*Cotton Spinning*). Yarns which have only been carded. Not so valuable or so strong as COMBED YARNS (*q.v.*)

Cardew Voltmeter (*Elect.*) *See* VOLTMETERS.

Cardinal Planes of Lenses (*Light*). These are the PRINCIPAL, FOCAL, *and* SYMMETRIC PLANES (*q.v.*)

Cardinal Points (*Astron.*) The N., S., E., and W. points of the horizon. The N. and S. points are the points at which the meridian (*q.v.*) intersects the horizon (*q.v.*)

Cardinal Points of Lenses (*Light*). In dealing with thick lenses, or systems of lenses, the calculations are much simplified by the use of a system of points on the axis of the lens, termed the CARDINAL POINTS. *See* PRINCIPAL POINTS, PRINCIPAL FOCI, SYMMETRIC POINTS, *and* NODAL POINTS.

Carding (*Cotton Spinning*). A most important process, being the final stage at which cotton is cleaned for ordinary cotton yarns. A badly carded cotton will produce an inferior spun thread. Three types of carders are in use, *viz.*: (1) Revolving Flats; (2) Wellman's Stationary Flats; (3) Roller and Clearer Carder. The first is the English system; the second and third the American. The third is for coarse and waste spinning.

Carding (*Linen Manufac.*) In linen manufacture the flax is not carded as cotton is, but is hackled or combed. This takes out all the short fibres. The waste is called Tow, and is carded and spun, making a coarse description of yarn.

—— (*Textile Fabrics*). In general, the operation of separating and reblending textile fibres.

Carding Engine (*Textile Manufac.*) A machine consisting of several large cylinders and small rollers covered with card clothing (*q.v.*) The large cylinders, termed SWIFTS, convey the material forward. The medium rollers, or DOFFERS, remove it from the swifts. The small rollers, termed WORKERS and STRIPPERS, separate the felted meshes of fibres and also assist in reblending them in conjunction with the swifts.

Card Lacing (*Lace Manufac.*) The operation of attaching the Jacquard cards (*q.v.*) to each other in the order necessary to produce the required pattern.

Card Nippers (*Lace Manufac.*) A hand punch for use in correcting mistakes or making alterations in the cards.

Card Puncher (*Lace Manufac.*) The person who punches the holes necessary in the Jacquard cards to enable the pattern to be produced in machine-made lace.

Cards (*Lace Manufac., etc.*) *See* JACQUARD CARDS.

Card Wire (*Eng.*) A brush of fine steel wire, used by fitters for cleaning out file teeth.

Carmagnole (*Cost.*) The dress affected by the Jacobins during the French Revolution of 1789. It consisted of a red cap, blouse, and a girdle of blue, white, and red.

Carmine (*Dec.*) A beautiful bright red pigment made by precipitating colouring matter obtained from COCHINEAL (*q.v.*), with a base such as alumina. It works well in oil and water, but soon fades on exposure to light. The colouring matter is CARMINIC ACID, a complex organic compound.

Carnallite (*Min.*) A chloride of magnesium and potassium, $MgCl_2 . KCl . 6H_2O$; Magnesium chloride = 34·2, potassium chloride = 26·88, water = 38·92. Massive, usually pinkish from impurities of ferric oxide. It is very deliquescent and strongly phosphorescent. It occurs in considerable quantity at Stassfurt in Saxony, where it is largely worked. It is used in glass manufacture, etc., as a source of potassium.

Carnation (*Paint.*) The various tones of pink used in painting flesh. It also signifies those parts of the body that are drawn naked.

Carnauba Wax. The wax deposited upon the leaves of the Wax Palm (*Copernicia cerifera*), indigenous to Brazil. The crude wax is obtained by boiling the leaves; it is of a dirty yellowish colour, very hard and brittle, being readily reduced, by pressure, to powder. Used in admixture with the softer waxes, such as paraffin, for making candles and wax polishes (*q.v.*)

Carnelian (*Min.*) A red translucent CHALCEDONY (*q.v.*), used largely for beads and seals. When found, the colour of the masses is very dark, but much of the colour is discharged on roasting.

Carnot's Cycle (*Heat*). The set of operations in a theoretically perfect HEAT ENGINE (*q.v.*) The working substance in the cylinder goes through the four following processes in succession: (1) Adiabatic Compression, (2) Isothermal Expansion, (3) Adiabatic Expansion, (4) Isothermal Compression. If these conditions could be realised in a steam or gas engine, the highest possible efficiency would be attained. *See* INDICATORS *and* INDICATOR DIAGRAMS.

Carpentry. The art of constructing and erecting the structural woodwork of a building, *i.e.* beams, joists, partitions, roofs, etc., as distinguished from JOINERY, which deals with the smaller and more finished parts, such as doors, windows, and staircases. As carpenters' work requires to be very strong and reliable, it should always be constructed on thoroughly scientific principles, and it is therefore erroneous to describe it as "rough" woodwork.

Carpentum (*Archæol.*) An antique two-wheeled carriage, protected by an awning and curtains. Used by Roman ladies at festal processions. Carpenta were also used by the Gauls and Britons.

Carpet. Woven or felt floor covering. Woven carpets are of two great types: (1) An ordinary woven fabric, *e.g.* Scotch or Kidder carpets; (2) Pile woven fabrics, *e.g.* Brussels, Axminster, Persian, Smyrna, etc.

Carrageen Moss (*Botany*). *Chondrus crispus* (class, *Rhodophyceæ*). This red seaweed is used in the preparation of a nutritive jelly.

Carrara Marble. A metamorphosed limestone of sedimentary origin. It is of exceptional purity and uniformity of composition. Usually regarded as a member of the Trias (*q.v.*) It is chiefly obtained from the quarries at Carrara, in Italy, and is much used for sculpture.

Carriage (*Carp. and Join.*) The rough inclined timber supporting the steps of wooden stairs.

—— (*Lace Manufac.*) A thin flat piece of steel, roughly triangular in shape, with a segmental base and a circular hole central with the body of metal forming the receptacle containing the brass bobbins. The two combined form a SHUTTLE.

Carriage Gain (*Cotton Spinning*). *See* PATCHING.

Carrier (*Eng.*) A holder which can be attached to a round rod, etc., when being turned in the lathe, to enable the driving chuck to rotate the work between the centres.

—— (*Optical Lantern*). A frame of convenient form which holds the small unframed slides which are usually made at the present time; the carrier remains fixed in the lantern, and enables the slides to be placed in position accurately and quickly.

Carrollite (*Min.*) A copper and cobalt sulphide, $CuS . Co_2 S_3$. Isometric. This rare mineral is chiefly of interest from the recent discovery in it of traces of RADIUM. It is found in the United States.

Carte de Visite (*Photo.*) The small size of print commonly used for portraits; it is about $3\frac{1}{2}$ in. by $2\frac{1}{4}$ in., *i.e.* about half the size of a QUARTER PLATE (*q.v.*)

Cartilage (*Zoology*). An elastic tissue which precedes bone as the constituent of the skeleton. It also forms efficient pads between the various bones. Cartilage consists of a matrix of CHONDRIN, containing cells and, in some cases, fibres.

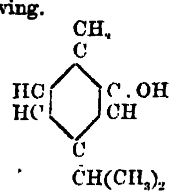
Cartisane. A small piece of parchment placed under embroideries to give relief.

Cartoon (*Art*). (1) A study or design made on paper for a painting of the same size which is to be executed in fresco or oil, especially the former, the design being traced through upon the fresh plaster of the wall. Cartoons are also executed in colours for designs in tapestry, mosaic, stained glass, etc. The cartoons of Raphael are well known examples. (2) An illustration in a newspaper or periodical relating to some current topic or event.

Cartouch *or* **Cartouche** (*Architect., etc.*) (1) A modillion in an internal cornice. (2) Also used to denote a shield-shaped, scroll-shaped, or oval ornament. (3) The oval used in Egyptian hieroglyphics to enclose certain characters expressing the names or titles of divinities and kings.

Cartridge Paper. Paper originally used in the manufacture of cartridges. It is cheap and useful for rough drawing.

Carvacrol.



Is an oil occurring in certain essential oils; boils at 236°. Obtained by heating camphor with iodine.

Carving. This term is now usually restricted to work executed in wood and ivory, the term "Sculpture" being applied to carving in stone, and "Chasing" to metal work. Carving was naturally practised at a date anterior to sculpture, and in early examples of sculptured stone the influence that wood-carving exercised on the sculptor is easily discernible. The Greeks excelled in ivory-carving, and some chryselephantine statues (*q.v.*) of marvellous beauty were executed by Pheidias. During the Gothic period (twelfth to sixteenth century) wood-carving reached a high standard, especially as regards the interior decoration of churches. The most celebrated wood-carver this country has produced is Grinling Gibbons (1648—1720), who, in addition to many other notable examples, executed the stalls of St. Paul's Cathedral. Efforts are being made at most art schools to revive this art, which, like so many other valuable and interesting handicrafts, has for several years past undeservedly suffered in the competition with work executed by machinery.

CARYATID. FROM ERECTHEUM.

Caryatid (*Architect.*) A carved figure of a female used as a column, as in the portico of the Erectheum. *See* ATLANTES.

Cascara Sagrada (*Botany*). *Rhamnus purshiana* (order, *Rhamnaceæ*). The dried bark is the source of the purgative drug of this name.

Cascarilla (*Botany*). *Croton Cascarilla* (order, *Euphorbiaceæ*). The dried bark is used in medicine as an aromatic tonic.

Case (*Typog.*) The receptacle from which type is gathered for composing. There is an upper and a lower case. The former, divided into various compartments, contains the capitals and the accented and dotted letters; the latter, likewise divided, contains the small letters, spaces, etc.

——, **Casework** (*Bind.*) Covers, cloth bound or otherwise, prepared separately from the book, which is afterwards fastened into them.

Cased Frame (*Carp. and Join.*) A window frame having the sashes hung with cords.

Case Hardening (*Eng.*) The production of a thin layer of steel on the surface of iron bodies by heating them to a bright red in contact with carbonaceous matter.

Casein (*Chem.*) The essential and characteristic albumin of milk. It is composed of carbon, hydrogen, nitrogen, oxygen, sulphur, phosphorus. It is an acid: insoluble in water, but its salts are readily soluble, and it is present in milk as its neutral calcium salt. It is precipitated from solutions of its salts by acids, even by carbonic acid; it may also be salted out by common salt and magnesium sulphate. The food Plasmon is said to be the sodium salt of casein. During the last few years casein has been largely used as a binding material in the manufacture of washable distemper or water paints (*q.v.*)

Casemate *or* **Casement** (*Architect.*) A large hollow moulding used in Gothic architecture, particularly in the Perpendicular style.

—— (*Carp. and Join.*) A window consisting of glazed doors hung to a solid frame, instead of sliding sashes.

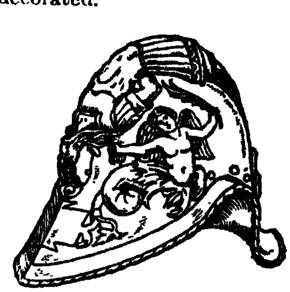
Cashmere. Soft, fine, silky fibre forming part of the fleece of the Cashmere goat of Thibet.

—— (*Woollen Manufac.*) Fine twill dress stuffs made of worsted yarns.

Cashmere Goat. *Capra hircus* (family, *Bovidæ*). A small variety of goat having a thick coat of wool beneath the long silky hair.

Casket *or* **Casquet.** A small coffer or box, generally made of some rare or precious material, wood, or metal, often highly decorated.

Casque (*Armour*). A term applied to all kinds of helmets. More precisely a species of helmet first worn in the reign of Henry VIII. It was intended more for parade than protection, and was, generally, elaborately ornamented. It had no visor.



CASQUE, MILANESE, c. 1540. BARON DE COSSON COLLECTION.

Casquetel (*Arm.*) A small helmet or steel cap without visor, but having a projecting umbril, and flexible plates to cover the neck.

Cassel Yellow. Oxychloride of lead — $PbCl_2 7PbO$.

Cassia Bark (*Botany*). *Cinnamomum cassia* (order, *Lauraceæ*). The bark of this plant is a frequent adulterant of cinnamon.

Cassiterite (*Min.*) An oxide of tin, SnO_2; Tin = 78·38, oxygen = 21·62 per cent. Often called tin stone. It crystallises in tetragonal prisms. Often twinned (*q.v.*) at an obtuse angle (geniculate twins). It is the most important ore of tin. The varieties WOOD TIN and TOAD'S EYE TIN are those which show a concentric banding. STREAM TIN is water-worn Cassiterite. It occurs in Cornwall, Devon, Saxony, Straits of Malacca, United States, Australia.

Cassock (*Cost.*) Originally almost any kind of long loose coat worn during the seventeenth and eighteenth centuries. A long, close-fitting garment worn by the Anglican clergy, originally under the gown; at the present time under the surplice. Also worn by any ecclesiastical official, cleric or layman.

Cast (*Eng., etc.*) (1) A twist in timber due to drying. (2) Applied to material suitable for casting (*q.v.*)

—— (*Sculp.*) (1) The name applied to a facsimile of an original piece of sculpture. It is generally executed in plaster, cast in a mould. The usual method of reproduction is as follows: The object of which a copy is required is first smeared with boiled soft soap; it is then covered, in sections, either with molten wax or wet plaster of Paris, until a mould of the whole has been obtained. This piece-mould is fitted together, and plaster and water are run into it. When the mould is removed there remains a facsimile of the original in plaster. (2) The name is sometimes applied to the mould or reversed impression in which the cast is made.

—— (*from Nature*). This may be taken either from a living or a dead body, and may be a cast of the entire frame or any portion, such as a hand or foot. The same process is followed substantially as in making a cast from sculpture.

Cast Holes (*Eng.*) Holes are cast to save metal or the expense of drilling; they are not accurate in size or position, and require careful finishing in exact work.

Casting (*Foundry*). (1) The metal object produced by pouring molten metal into a mould of requisite shape. (2) The operation of producing the above.

Casting Ladle (*Foundry*). The large receptacle used for carrying and pouring out the molten metal.

Casting On (*Foundry*). *See* BURNING ON.

Casting Upright, on End (*Foundry*). The fixing of a long mould in a vertical position (usually in a pit); the metal is then often poured down a long tube or channel in the sand, and enters the mould at the bottom. This produces a sound casting, as gas bubbles, etc., are driven out at the top of the mould; scoriæ, etc., collect in a HEAD (*q.v.*)

Cast Iron. *See* IRON.

Cast Iron Pipe (*Eng.*) Used for water and gas mains, and for steam pipes when the pressure is not too great; the cheapest form of iron pipe.

Castle. Generally a series of strong buildings connected together and originally intended to serve as a fortress. Such fortresses were chiefly the outgrowth of feudalism, and until after the Norman Conquest were seldom to be found in England. The thirteenth century marked the greatest advance in the fortification of castles. The strongest part of the mediæval castle was the donjon or keep, intended to form the last retreat of the garrison.

Castoreum. A waxy substance from the anal glands of the beaver, *Castor canadensis* (family, *Castoridæ*). Large quantities are used in medicine on the Continent.

Castor Oil. Oil obtained from the seeds of *Ricinus communis* (order, *Euphorbiaceæ*), a plant cultivated in India, the United States, Java, and elsewhere. The refined oil is almost colourless, very viscid; thickens and becomes rancid on exposure to the air, but does not dry. The best quality is produced by pressure of the bruised seed, is used for medicinal purposes, and is known as "cold drawn." Second and third qualities are obtained by heating the same seeds and again pressing them. These qualities are used in the manufacture of lubricants and for dressing leather, particularly morocco and chamois leathers. Castor oil is expressed in several parts of England from imported seed. Sp. gr. 0·960 to 0·966 at 60° F.

Casts (*Geol.*) Properly speaking, this term should be restricted to such cases as those where an alien substance has filled a cavity or mould formed by the removal of some pre-existent rock, mineral, or fossil, and thus imitated its form; but in practice the term is often applied to the mould itself.

Cast Steel (*Eng.*) Ingots of steel obtained by breaking up and melting BLISTER STEEL in a crucible. *See* STEEL.

Catacomb. A subterranean place for burial of the dead, consisting of galleries or passages, the bodies being deposited in recesses called *loculi*, excavated in the sides. Applied originally to the cemetery under the Basilica of St. Sebastian, Rome; it is now used in respect of all of the many subterranean places of sepulture in or near Rome, as well as those of Cairo, Naples, Paris, etc.

Catafalque. A decorated platform on which a coffin is placed in church during a funeral service.

Catalysis *and* **Catalytic Action** (*Chem.*) The speed of certain reactions is considerably changed by the introduction of a third substance, which itself remains unchanged at the end of the reaction. The action exercised by such a substance is called a catalytic action or catalysis, and the substance is called a catalytic agent or catalysor. An example of such a change is the conversion of starch into dextrose and dextrine by water; by heating with water alone the change is very slow, but in presence of a little sulphuric acid the speed is enormously increased. Other examples are the conversion of cane sugar to dextrose and lævulose by a dilute acid; the hydrolysis of esters by the same means; the union of sulphur dioxide and oxygen in presence of platinum black; the decomposition of hydrogen peroxide also, by finely divided platinum. The amount of catalytic action is, up to certain limits, proportional to the amount of catalysor present, and it is also dependent on temperature. *See also* ENZYMES.

Catch Bar (*Lace Manufac.*) An approximately square iron bar long enough to extend over the whole width occupied by the carriages. A brass blade attached to the bar engages with certain projections on the carriages, and moves them all simultaneously.

Catch Plate (*Eng.*) A small face plate (*q.v.*) for a lathe: it carries a projecting pin, which engages with a carrier fixed on the end of a bar, etc., which is being turned in the lathe.

Catchword (*Typog.*) The first word of the following page of a book, inserted at right-hand lower corner in the "whiteline." Not generally used now except in encyclopædias and dictionaries.

Catechol, Pyrocatechin, Orthodihydroxybenzene. $C_6H_4(OH)_2$. White crystalline solid, soluble in water; melts at 104°. Gives, like all orthodihydroxybenzene derivatives, a green colour with ferric chloride; it occurs in beechwood tar and catechu (*q.v.*) Obtained by heating protocatechuic acid (*q.v.*), and by heating either 1 : 2 bromphenol or 1 : 2 phenolsulphonic acid with caustic potash.

Catechu. An extract of the leaves and young shoots of *Uncaria Gambia* (Singapore, etc.) and from *Acacia catechu.* The juice is evaporated and is made into cubes which have a reddish-brown colour; it contains catechu-tannic acid, catechin, and catechol. On distillation it gives catechol. Used in dyeing and calico printing, and as an astringent in medicine. *See also* DYES AND DYEING.

Catenary. The curve which a heavy cord or chain assumes when suspended between two points.

Cateract (*Eng.*) A hydraulic arrangement for regulating the valves in Cornish pumping engines; very little used now.

Catgut. Tough strings made from the prepared intestines of sheep. A strong driving-cord for machinery is made from the intestines of horses and asses *See also* WASTE PRODUCTS.

Cathedral Glass. A name commonly applied in the building trades to combinations of coloured glass.

Catherine Wheel Window (*Architect.*) *See* ROSE WINDOW.

Cathetometer (*Physics*). A microscope or telescope mounted horizontally on a vertical stand. It can be either raised or lowered, but it always remains horizontal. The rise or fall can be accurately read on a finely divided scale, thereby giving measurements of vertical heights which do not exceed the range of the scale of the instrument.

Cathode *or* **Kathode** (*Elect.*) The conductor, or ELECTRODE, by which an electric current leaves a liquid or gas; it is usually a piece of carbon or metal in the shape of a flat plate, disc, rod, etc. *Cf.* ANODE.

Cat's Eye (*Min.*) A variety of QUARTZ (*q.v.*) showing a fine fibrous structure, so that when cut *en cabochon* it gives a sudden flash of light in certain directions. Fine examples come from Ceylon and Malabar. *See also* PRECIOUS STONES.

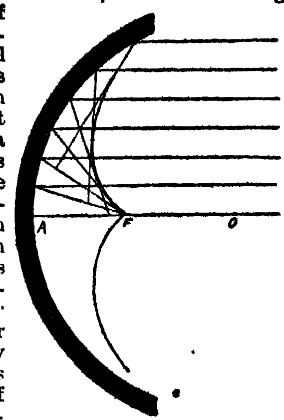
Cat's Head (*Architect.*) A Norman ornament, resembling the beakhead, but having a protruding tongue instead of a beak. *See* BEAKHEAD.

Caulicoli (*Architect.*) The eight stalks which spring from the upper row of leaves in a Roman Corinthian capital. This term is also used to denote either the volutes in which these eight stalks terminate, or the stalks and scrolls together. It is also written Cauliculus, Caulicolus, and Caulecole. *See* ARCHITECTURE, ORDERS OF, *and* CORINTHIAN.

Caulk *or* **Calk** (*Plumb.*) To run lead into the socket of an iron pipe and hammer it in with a caulking chisel. *See also* CALKING.

Causia (*Archæol.*) A broad-brimmed hat worn by the ancient Romans. Originally worn by the Macedonian kings.

Caustic (*Light*). A curved line or surface produced by the intersection of rays from reflecting or refracting surfaces of certain forms. For example, in a spherical mirror the reflected rays do not pass through any one focal point, but touch a curve with a "cusp," whose point is on the axis of the mirror. The caustic produced by the reflection of parallel rays from a spherical mirror is shown in the illustration. The rays near the axis of the mirror OA intersect at or very near a point F, which is the principal focus of the mirror. The distance AF is half the distance AO, which is the radius of curvature of the mirror.



CAUSTIC CURVE.

Caustic Alkali. *See* ALKALI.

Causticising Pan (*Paper Manufac.*) A cylindrical vessel, usually fitted with agitators, in which carbonate of soda is converted into caustic soda.

Caustic Potash. *See* ALKALI.

Caustic Soda. *See* ALKALI.

Cave Breccias (*Geol.*) A cemented mass of angular fragments of any kind (not usually limestone or bone) which have fallen into a subterranean cave or a fissure, from above, or have been washed into it by torrents. It may be of any age, but it is usually of comparatively recent origin.

Cave Earth (*Geol.*) A general term applied to the loam, sand, or clay which has found its way into caves (usually in those of limestone districts) by the action of running water.

Cavendish Experiment (*Physics*). An experiment of Henry Cavendish for finding the absolute force between two attracting masses. From this absolute force it is possible to calculate the mass of the earth. Cavendish found it to be 5·448 times the mass of an equal volume of water. This experiment has been repeated by later observers with different forms of apparatus, and the latest results obtained show that the actual density of the earth is about 5·527 times that of water.

Cavern (*Geol.*) Generally used as a synonym for cave; but it would be conducive to clearness if the term cave were restricted in geological phraseology to the subterranean chambers formed by the solvent action of waters upon limestone, and if the name cavern were used for the natural underground excavations, such as those which are produced by the mechanical action of the sea. The term grotto might in that case be employed for the rock cavities often left in lava beds.

Cavetto (*Architect.*) A hollow moulding. In Roman work its section is a quarter circle; a Grecian cavetto has a more graceful contour.

CAVETTO.

Caviare. A Russian food preparation made from the roe of the sturgeon, *Accipenser sturio* (sub-order, *Chondrostei*).

Cavo-Relievo (*Architect.*) Sculpture, in which the highest part of the relief is level with the general surface of the stone; much used in Egyptian sculpture. *See* BASSO-RELIEVO, ALTO-RELIEVO, MEZZO-RELIEVO, *and* INTAGLIO.

Cawk (*Min.*) A miner's term for BARYTES (*q.v.*)

Caxton. Any book printed by William Caxton, England's first printer, is known as a "Caxton." All his productions are in black letter, and were issued between the years 1474 and 1491. Although a most prolific printer, copies of his publications are now both rare and valuable. While many of his later publications have disappeared altogether, several copies of the first edition of his earliest and best known books, *The Recuyell of the Historyes of Troye* and *The Game and Playe of the Chesse* are still extant. His greatest work, *The Golden Legend*, published about 1484, was profusely illustrated with wood cuts. Of the first edition of this work many copies remain. The finest collections of "Caxtons" are those in the British Museum and the Rylands Library, Manchester.

Cayenne Pepper. *See* CAPSICUM.

Cd (*Chem.*) Symbol for CADMIUM (*q.v.*)

Ce (*Chem.*) Symbol for CERIUM (*q.v.*)

Cedar. *See* WOODS.

Cedar Wood Oil. *Cedrus*, several species (order, *Coniferæ*). An oil obtained by distillation from cedar wood shavings.

Ceiling Joists (*Carp.*) The timbers (below the floor joists) to which the laths are nailed. *See also* FLOORS.

Celadon (*Pot.*) Porcelain in which the colour is mixed with the glaze and burnt in at the first firing.

Celebe (*Pot.*) A Greek vase in form resembling an urn and having two handles.

Celestial Equator (*Astron.*) The GREAT CIRCLE (*q.v.*) on the celestial sphere, whose poles are the celestial poles.

Celestial Poles (*Astron.*) The two points about which the celestial sphere appears to revolve.

Celestial Sphere (*Astron.*) An imaginary hollow sphere, whose centre is at the eye of the observer. A line drawn from the centre to each of the heavenly bodies cuts this sphere at a point which is the apparent position of the body in question.

Celestine (*Min.*) Strontium sulphate, $SrSO_4$. Strontia = 56·4, sulphuric acid = 43·6 per cent. It crystallises in rhombic tables. The crystals are colourless, or more often pale blue, very brittle. It is found frequently in association with gypsum, rock salt, and sulphur. Bristol and Lake Huron are two of the principal localities.

Cell *or* **Cella** (*Architect.*) The space enclosed within the walls of a Grecian temple. Sometimes this space was undivided, and formed the principal chamber, or NAOS, in which was placed the statue of the deity. In other cases the cella was divided into two portions—the larger portion, the NAOS, in the front, and a smaller chamber, called the OPISTHODOMUS, used as a treasury, at the back. The naos was approached through a columnar porch, the pronaos; the opisthodomus through the rear porch, the POSTICUM or EPINAOS. The term cell is also used to denote the filling in between the ribs of Gothic vaulting. *See* SEVERIES, NAVE, *and* ANTA.

Cell *or* **Cella** (*Biology*). The unit of an animal or plant organism. It consists of a mass of protoplasm containing a nucleus, and may, or may not, have a cell wall.

Cellar Dwellings (*Hygiene*). Use of a cellar as a dwelling is absolutely prohibited by the Public Health Acts. A cellar may not be occupied at all unless it accords with the requirements laid down in the Acts. These relate to height, drainage, sanitary accommodation, ventilation, light, etc.

Cells, Primary. The primary cell is a means of obtaining electrical energy by the actual consumption of some metallic element, usually zinc, which is turned into its sulphate or some other compound. The cell cannot then be used again without introducing an entirely fresh material, thereby differing from the storage cell or accumulator (*q.v.*) It may be compared to a kind of furnace, in which the zinc is the fuel. The essential parts of a cell consist of the negative plate, which, as mentioned above, is almost invariably zinc; a positive plate, which is commonly platinum, copper, or carbon; an exciting liquid, which acts chemically on the zinc; and finally some material which may be termed the "depolariser." The function of the latter body is to furnish a regular supply of oxygen in the neighbourhood of the positive plate, and thereby to destroy the free hydrogen which would be liberated there, and which if allowed to accumulate would stop the action of the cell. The main essentials of a good cell are as follows: (1) The electromotive force should be constant; (2) The internal resistance of the cell should be as small as possible; (3) The cell must be free from polarisation; (4) The chemical action in the cell should cease when the current is no longer flowing. The first condition (electromotive force) depends entirely upon the chemical nature of the materials employed, and is always constant so long as the nature and condition of the materials are the same; it is perfectly independent of the size of the cell or distances between the plates. The internal resistance of the cell, however, depends very largely upon its size and the distance between the plates, and can be diminished by making the plates large and bringing them close together. Freedom from polarisation depends (in the majority of cases) upon a sufficient and regular supply of oxygen being furnished by the polarising agent. The last condition is one of difficulty of attainment in most classes of cell; and in the more active forms of primary cell it is necessary to withdraw one or both plates from the fluid. The chief forms of cell in common use are as follows: (1) *Dichromate Cell:* This consists essentially of a plate of zinc and a plate of carbon, the exciting fluid being dilute sulphuric acid, and the depolariser a solution of potassium dichromate which is mixed with the acid. This mixture is very active, and it is absolutely necessary that the plates should be withdrawn when the cell is not in use. Instead of potassium dichromate, chromic anhydride (CrO_3) or potassium chromate (K_2CrO_4) may be used. An improvement may be made by putting the carbon plate and the potassium dichromate solution into a porous pot, leaving the zinc in the dilute sulphuric acid: in most cases, however, the fluids are mixed. The electromotive force of this cell is about two volts. (2) *Grove's Cell:* The positive plate is a piece of platinum foil, which is immersed in a depolariser consisting of strong nitric acid in a porous pot; the negative plate is zinc in dilute sulphuric acid. This is a very good cell; but the use of nitric acid is

somewhat objectionable both from the dangers of handling the acid itself, and from the corrosive fumes of the oxides of nitrogen which are given off as the acid parts with a portion of its oxygen. For this reason a Grove's battery will require to be kept under a hood with a steady draught to carry off the fumes. The electromotive force is about 1·9 volts. (3) *Bunsen's Cell:* This resembles Grove's cell in all respects but one, *viz.* that the positive plate is a rod of carbon instead of platinum foil. Its electromotive force and other properties are much the same as those of Grove's cell. (4) *Daniell's Cell:* The negative plate is zinc in sulphuric acid, as before. The positive plate is copper in a saturated solution of copper sulphate, the two fluids being separated by a porous pot. In this case no hydrogen is actually set free, but the copper sulphate is acted upon by the nascent hydrogen, metallic copper being formed, and deposited upon the copper plate. This deposition of copper does not alter the nature of the positive plate, and therefore there is no alteration in the electromotive force. The cell yields an electromotive force of 1·07 volts, and is remarkably constant in its action; on this account it is a very great deal used in telegraphic work. (5) *Leclanché Cell:* The negative plate is zinc acted on by a solution of ammonium chloride. The positive plate is a rod of carbon packed in a mass of manganese dioxide, which furnishes a supply of oxygen, and therefore acts as a depolariser. When this cell has been running for a very short time, it becomes polarised, and it is some time before the manganese dioxide can destroy this polarisation. If, however, the cell be given a comparatively long rest between short intervals of use, it easily recovers, and will last a very long time with no further attention than the addition of a little water. It is chiefly used for intermittent work, such as the ringing of electric bells. (6) *Dry Cells:* The so-called dry cells really consist of some form of Leclanché cell, in which the exciting fluid is mixed with some material to make it into a kind of damp paste, as a perfectly dry cell would be useless. There are many modern forms of dry cell, most of which have for their object the reduction of the internal resistance, which naturally tends to become very great when the cell no longer contains a mass of fluid. (7) *Lalande's Cell:* This is a zinc and copper cell, but the polariser consists of a mass of copper oxide surrounding the copper. The zinc is acted upon by a solution of caustic potash, KOH, in which the metal dissolves. It has a low electromotive force, about ·8 volts, but is a reliable and constant cell. In addition to the above, certain primary cells are constructed for the purpose of serving simply as a standard of electromotive force. In all these the object is not to obtain a current at all, but to ensure that the voltage shall be as constant as possible. Clark's cell (*q.v.*) is one of the best known and most reliable forms.

Celluloid. Is a mixture of camphor and pyroxylin (a mixture of the tetranitrate and pentanitrate of cellulose). The camphor is dissolved in alcohol, and the pyroxylin added, and the mass worked together between rollers; then warm-pressed. Celluloid is highly inflammable, but not explosive; it may be coloured by adding the required colour before working up the mixture. Largely used as a substitute for ivory, horn, and bone in combs, various ornaments, etc.

Cellulose, $(C_6H_{10}O_5)n$. Examples of very nearly pure cellulose are good Swedish filter paper; well washed linen; purified cotton wool. It has an organised structure; its chemical constitution is unknown. A solution of copper hydroxide in ammonia (Schweitzer's reagent) dissolves cellulose, and a hydrated cellulose is obtained by evaporating the solution or precipitating it by salt or acids. This fact has received several important technical applications, as in papermaking, making artificial silk (lustracellulose), making boards which are used in building. Zinc chloride and alkaline sulphocarbonates also dissolve cellulose; the solution in the latter case is called VISCOSE. Both these solutions are used in making artificial silk (lustracellulose). Strong solutions of caustic soda, (NaOH), act on cellulose, a compound, $(C_{12}H_{20}O_{10}Na_2O)n$, being formed which, on washing, gives a hydrated cellulose. When cotton goods are treated in this way, and tightly stretched to prevent shrinkage, the cotton is MERCERISED—it becomes lustrous and dyes better, especially with turkey red. The action of a mixture of nitric and sulphuric acids is very varied. *See* COLLODION, GUNCOTTON, PYROXYLIN, CELLULOID. When filter paper is dipped in sulphuric or nitric acid of proper strength, and then withdrawn, it becomes toughened; with a rather stronger sulphuric acid, unsized paper gives PARCHMENT PAPER; with concentrated sulphuric acid the cellulose dissolves—on dilution of the product and boiling, glucose (a sugar) is produced. This is the origin of the popular expression "making sugar from rags." Bleaching powder solution in presence of air, boiling dilute nitric acid, ferric compounds in presence of light oxidise cellulose—the last producing the well known "iron stain" on linen. Cellulose is not digested when taken with food; hence the necessity of cooking starchy foods, the cell walls of which, consisting of cellulose, are burst by the process of cooking.

Celsius' Scale (*Heat*). The CENTIGRADE SCALE (*q.v.*)

Celt (*Archæol.*) An implement of stone, bronze, or iron, with chisel-shaped edge, found among the remains of prehistoric man. A SOCKET or POT CELT is one with a hole at the end for receiving a handle.

Cement (*Build.*) *See* CEMENTS.

Cementation (*Metallurgy*). The older process for the manufacture of steel. Bars of wrought iron are packed in firebrick boxes or troughs, termed CONVERTING POTS, along with charcoal powder, and heated in a furnace for some days. A part of the carbon is gradually absorbed by the iron, converting it into steel. The process is now largely superseded by the BESSEMER PROCESS (*q.v.*) *See also* STEEL.

Cement Fillet (*Build.*) A strip of cement put in the angle where the roof joins the wall, instead of lead flashing; it serves to make a watertight joint between the roof and the wall.

Cementing Materials in Rocks (*Geol.*) As a rule the cement which unites the particles of rocks of clastic origin is silica, lime, or iron; but various other mineral substances occasionally occur along with these, or may occur quite alone. In nearly all cases the cementing matter has been carried in by the action of percolating waters.

Cement Joggle (*Build.*) A V-shaped recess cut in the vertical joints of stonework, and filled in with cement to strengthen the joint; it serves as a kind of connecting piece or DOWELL.

Cements (*Build.*) Of these, by far the most important is ordinary mortar. This is defined in the building rules of the London County Council as

consisting of one part of freshly burned lime, mixed with three parts of clean sharp sand free from earthy matter. Lime itself is produced by heating chalk or limestone, which is a more or less pure form of calcium carbonate. On heating, calcium oxide, CaO, is left behind. When this is "slaked" or treated with water, a portion of the water becomes chemically combined with it, forming calcium hydrate, $Ca(OH)_2$. The setting of the mortar in the masonry appears to be due mainly to the absorption of carbonic acid gas from the air, which converts the calcium hydrate into calcium carbonate; but there is no doubt that the silica in the sand also enters into some kind of combination, helping to produce a hard mass which adheres firmly to the stones or bricks between which the mortar is placed. *Hydraulic Lime:* If a limestone contain a certain amount of clay, or material resembling clay in chemical composition, the lime made from it has the peculiar property of being able to harden under water to a greater or less extent; such lime is termed HYDRAULIC LIME. Its action appears to be due to the formation of a compound between the lime and the silica contained in the clay, and this hardens independently of any absorption of carbonic acid, and therefore does not require exposure to the air. The same property is, however, possessed in a greater degree by the following cements. *Portland Cement:* A mixture of one part of lime and two parts of clay is thoroughly incorporated by grinding together. It is then dried in the air and cut into blocks, which are placed in a suitable kiln and burned at a glowing heat. Care must be taken in this operation that the materials are not actually melted, as, if they were, a glassy substance would be produced, which would be quite valueless. After burning, the substance is ground to an extremely fine powder. This part of the process is very important to the successful action of the cement, and it may be noted that the greater part of the product from the grinding mill ought to be sufficiently finely ground to pass through a sieve with seventy-six meshes per linear inch. Portland cement may be mixed with a considerable quantity of sharp sand, and forms an extremely durable and strong cement. Portland cement is frequently adulterated by the addition of foreign materials, of which the chief are gypsum, slag, slate, and unburned limestone. These have a very deleterious effect on the strength of the cement. *Roman Cement:* A cement made from material somewhat inferior to Portland. It is about a third of the strength of Portland cement, and is about two-thirds of the price. Its principal advantage is that it sets more quickly. *Plaster of Paris:* This consists of gypsum which has been heated to drive off its water of hydration. It gives a beautiful white and smooth surface, but has very little strength. *Keen's Cement:* This consists of burned gypsum, which has been heated with a solution of lime, dried, re-burned, and ground. It is very much harder and stronger than plaster of Paris. *Parian Cement:* Plaster of Paris mixed with a 10 per cent. solution of borax. *Stucco:* Plaster of Paris treated with a solution of gelatine or glue.

Cement Stone Group (*Geol.*) A subdivision of the Scottish Lower Carboniferous Rocks which corresponds to the Ballagan Beds of the west of Scotland and the Lower Limestone Shale. The name was given on account of the occurrence, in the shales of these rocks, of thin bands of argillaceous limestone like those found in the Lias. They are mostly quite useless for the manufacture of cement. These rocks were erroneously supposed to be of older date than any carboniferous rocks known in England.

Cement Tester (*Build., etc.*) A small TESTING MACHINE used for finding the tensile strength of samples of cement, which are moulded into a special form for the purpose. *See* TESTING MACHINES.

Cendal. *See* SENDAL.

Censer (*Archæol., etc.*) A vase or vessel for burning incense. The heathen censer generally stood, and was in form of a tripod. The Christian Church uses a swinging censer, hung by chains. In the Roman Catholic Church they are called THURIBLES.

Centaur (*Myth.*) A fabulous creature having the body of a horse and a man's torso, head, and arms issuing from the neck of the animal. Often introduced in Greek and Roman sculpture.

CENTAUR (*Myth.*)

Centering *or* **Centring** (*Build.*) The timber frame supporting an arch during the process of construction.

—— (*Eng.*) Marking the centres on work for the drilling machine, or the ends of the axis of a piece of work to go into the lathe, by means of a centre punch.

Centigrade Scale (*Heat*). The scale of temperature universally used in science; the difference in temperature between the freezing and boiling points of pure water is divided into 100 equal parts, the former being marked 0° and the latter 100°. The scale thus obtained is extended by means of equal divisions or degrees above and below the fixed points.

Centimetre. *See* WEIGHTS AND MEASURES.

Central Load (*Eng., Build., etc.*) A weight which is concentrated at the centre of a beam or other structure.

Centre Chuck (*Eng.*) A chuck (*q.v.*) which automatically adjusts work of a cylindrical or circular form, so that its axis coincides with the line of centres of the lathe. The jaws are moved by a screw, lever, or other device, and are so connected together that however they are moved they are always equidistant from the central axis of the chuck.

Centre Flower (*Plast.*) A plaster ornament in the centre of a ceiling.

Centre Nailed (*Build.*) Slates having the nail holes near the centre of their length.

Centre of a Lens (*Light*). In the case of a very thin lens, the centre is the point at which the axis cuts the lens: a ray passing through this point will not be bent by the lens, whatever its direction. In the case of a lens of finite thickness it is a point (which is not necessarily within the lens) such that any ray passing through it is undeviated. Let AC be a

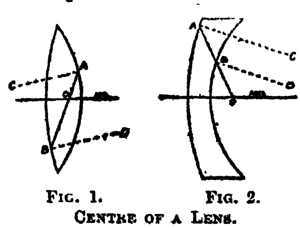


FIG. 1. FIG. 2.
CENTRE OF A LENS.

NORMAL (*q.v.*) to one surface of the lens at A, and BD be the normal to the second surface which is parallel to AC. Join AB, then the point O is the centre.

Centre of Curvature. If two normals be drawn to any curve, they will intersect on the concave side of the curve. If the two points from which they are drawn approach one another till they are at an infinitesimal distance apart, then the point of intersection of the two normals is called the CENTRE OF CURVATURE of the curve, and the distance from the curve to this centre is termed the RADIUS OF CURVATURE.

Centre of Gravity (*Phys., Mechanics*). A point in a body through which passes the resultant of all the parallel forces exerted by gravity on the particles composing the body. In more practical language the centre of gravity may be said to be a point about which the body would balance in whatever position it might be placed.

Centre of Oscillation (*Physics*). *See* PENDULUM.

Centre of Pressure (*Phys.*) When a fluid pressure is applied to any surface, a point can be found through which the resultant pressure (or resultant of all the forces exerted on every element of area of the surface) acts. This point is the Centre of Pressure.

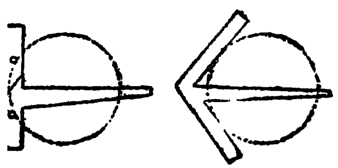
Centre of Suspension (*Physics*). *See* PENDULUM.

Centre Piece (*Plast.*) *See* CENTRE FLOWER.

Centre Plates (*Pattern Making*). Metal plates used for holding together parts of a jointed pattern while being turned in the lathe.

Centre Punch (*Eng.*) A punch used for marking the point where the centre of a hole is to be drilled, or as a guide for some other measurement.

Centre Square (*Eng.*) A form of square with two studs on the stock. When these studs touch the circumference of a circle, one edge of the blade of the square passes through the centre of the circle, so that by marking a line with two positions of the square the centre of the circle can be found. In another form there are two straight edges fixed at an angle with each other, forming a wide V, between the arms of which the circular object can be placed. The blade of the square is fixed so that one edge bisects the angle of the V, and therefore passes through the centre of the square. Both forms of centre square are shown in the illustration.



CENTRE SQUARES.

Centre Weighted Governor (*Eng.*) An engine governor which has a heavy weight attached to the central spindle, so that it is moved up and down when the speed varies. *See* GOVERNOR.

Centrifugal *and* Centripetal Force. When a body is constrained to move along a curve, it exerts a force along the outward-drawn normal to the curve. This force is termed the Centrifugal Force. Its amount is $m\frac{v^2}{r}$ where m is the mass of the body, v its velocity, and r the radius of curvature of the path. The force which causes the body to continue in its curved path is equal in amount, but opposite in direction, to the centrifugal force: it is often termed the CENTRIPETAL FORCE. If a mass, attached to a string, be whirled round in a circle, the centripetal force is the pull exerted by the string.

Centrifugal Pump. A pump in which a high velocity is given to the water by the blades of a rapidly rotating fan. Its continuous action and the absence of valves are its chief advantages.

Ceramics. *See* POTTERY AND PORCELAIN.

Ceramography. Historical and technical description of pottery.

Cerebellum (*Zoology*). The term applied to a part of the hind brain. It functions in maintaining the balance of the body.

Cerebrum. The mass of nervous matter forming the anterior portion of the brain. In the higher vertebrates it constitutes the largest part of the brain, and in man fills nearly the whole cavity of the skull.

Ceresine. An earth wax obtained from OZOKERITE (*q.v.*) Used principally for mixing with beeswax.

Cerium (*Chem.*). Ce. Atomic weight, 140. A rare metal resembling iron in appearance; it occurs as silicate in the rare mineral CERITE; it belongs to the same group of elements as carbon in the Periodic System (*q.v.*) The dioxide CeO_2 forms 1 per cent. of the WELSBACH INCANDESCENT MANTLE (*q.v.*) The crude sulphate made from cerite is used in dyeing; the oxalate is used in medicine to prevent vomiting.

Cerography. (1) Writing, painting, or engraving on wax. (2) The encaustic painting of the ancients. (3) Painting in wax colours.

Ceroplastic. The art of modelling in wax. This art was practised in early times and in the Renaissance, the figures often being coloured. Some of the finest examples are Michael Angelo's studies, now at South Kensington.

Cerulean (*Paint.*) Of the colour of the blue sky: azure.

Cerulein. *See* DYES AND DYEING.

Cerussite (*Min.*) Carbonate of lead, $PbCO_3$. Oxide of lead = 83·5, carbonic acid = 16·5 per cent. Usually in rhombic crystals, but also massive. The lustre is peculiarly brilliant. Twinning often produces a radial arrangement of the individual crystals. It is probably derived from the decomposition of Anglesite in many cases. In quantity it is a valuable ore of lead. Found at Caldbeck Fells, Alston Moor in Cumberland, Cornwall, Dumfriesshire, and many places abroad.

Ceryl Alcohol. $C_{27}H_{55}OH$. A white crystalline mass; melts at 79°. Combined with CEROTIC ACID, $C_{27}H_{54}O_2$, it forms CHINESE WAX, $C_{26}.H_{53}COOC_{27}H_{55}$. It belongs to the same series of alcohols as common or ethyl alcohol.

Cesspools (*Hygiene*). Cavities to receive the sewage from houses in districts where the water-carriage system for the removal of waste matters has not been adopted. They should fulfil the following conditions: Be absolutely watertight, well ventilated, placed a safe distance from wells and streams, regularly emptied and cleansed, and without overflows.

—— (*Plumbing*). A box lined with lead, at the end of a gutter.

Cestus (*Archæol.*) A boxer's glove, used by the Greeks and Romans. It was generally formed of thongs of leather wound round the hand and wrist. Metal bosses were sometimes added, or the leather was loaded with lead or iron.

Cetyl Alcohol. $C_{16}H_{33}OH$. A white crystalline mass; melts at 49·5°. Combined with palmitic acid, forming cetyl palmitate, $C_{15}H_{31}COOC_{16}H_{33}$, it is the chief ingredient of SPERMACETI. It belongs to the same series of alcohols as common or ethyl alcohol.

C.F. (*Music*). Abbreviation for *canto fermo*.

Chabazite (*Min.*) A rhombohedral ZEOLITE (*q.v.*) occurring in drusy cavities (*q.v.*) in basic lavas. Composition, a hydrous silicate of aluminium, calcium, and potassium. Found at Giants' Causeway, Ireland, Greenland, United States, etc.

Chain. A number of loops of metal linked together. Each loop is welded up, in the case of large chains; in smaller ones it may be brazed, soldered, or merely bent into form, according to its material and the purpose for which it is required.

—— (*Surveying, etc.*) In surveying, the surveyor's chain is the instrument most frequently employed for the direct measurement of distances. It is in the form of a chain of one hundred links of iron or steel wire. Its length is usually 66 ft. *See also* WEIGHTS AND MEASURES.

Chain Adjustment (*Cycle*). The device by which the hub of the back wheel and the sprocket wheel on it can be moved farther from the crank axle to "take up" the slackness due to stretching of the chain. The back axle is moved in the fork ends by means of the "adjusters," and held in place by the nuts which screw the collars on the axle closely up to the slotted fork ends.

Chain Barrel (*Eng.*) A cylinder on which a chain is wound up in some forms of machinery, such as cranes. It may have a groove in which the chain can lie, or may be a plain cylinder.

Chain, Driving (*Cycles and Cars*). There are two chief types: BLOCK CHAINS, in which the two side links are connected to a solid piece or "block," and ROLLER CHAINS, in which the screwed pin on which the links hinge runs through a tubular roller, which can revolve as it passes over the teeth of the chain wheels, thereby diminishing the friction. Many special forms of driving chains are now made for the cycle, motor, and engineering trades. *See also* CYCLES.

Chain Moulding (*Architect.*) An enriched moulding resembling a chain, used in Norman work.

Chain Pillars (*Mining*). Masses of rock left on each side of a gangway or principal level to prevent the collapse of the roof.

Chain Pump (*Eng.*) A pump in which a number of discs, fixed on a chain, run through a cylindrical barrel, and serve as a succession of pistons for raising water up through the barrel.

Chain Riveting (*Eng.*) An arrangement of rivets in parallel rows.

Chain Survey. A survey carried out by means of the chain only, no theodolite, etc., being used. *See also* TRIANGULATION.

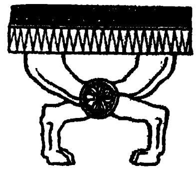
Chain Warp (*Cotton Weaving*). A WARP (*q.v.*) of considerable length and fewer threads than a balled warp. It is looped or linked in the form of a chain so as to facilitate its progress during dyeing and sizing operations. Usually prepared on a chain or lease warper.

Chain Wheel (*Cycles and Motor Cars, etc.*) A wheel with teeth of a suitable form to engage the links of a driving chain without shock or undue friction. The block or roller (*see* CHAIN, DRIVING) must be able to lie between two teeth with the necessary clearance.

Chair (*Eng.*) The iron casting by which a rail is fixed to the sleepers on a railway. The rail drops into a wide opening in the chair, and is fixed by large wedges of wood.

—— (*Glass Manufac.*) A group of workmen in a glass manufactory who attend to a certain number of crucibles. *Cf.* COMPANIONSHIP (*Typog.*)

——**, Curule.** A folding seat used by Roman officials as a mark of distinction. It was generally richly decorated with ivory inlay, gold, etc. Those entitled to use such a seat were called *Curule magistrates*.



CHAIR, CURULE.

Chair Rail (*Carp.*) A wood moulding fixed to the wall to protect the plaster from injury by the backs of chairs.

Chair, Sedan. So called from *Sedan* in the north of France, where first used. A closed vehicle for carrying one person. It was glazed at the sides and in front, often elaborately decorated, and was borne by two men by means of shoulder straps attached to two long poles. The Sedan chair was extensively used in this country by the wealthier classes during the seventeenth and eighteenth centuries.

Chalcanthite (*Min.*) Hydrous sulphate of copper, $CuSO_4 . 5H_2O$. Oxide of copper = 31·8, sulphuric anhydride = 32·1, water = 36·1 per cent. Also called BLUE VITRIOL. It occurs in sky blue crystals of the anorthic system and in encrusting masses. It results in nature from the decomposition of copper pyrites. Found in Cornwall, Ireland, the Harz, etc.

Chalcedony (*Geol.*) A mixture of COLLOIDAL (*q.v.*) or opaline silica with a microcrystalline form whose exact nature is as yet imperfectly known. Provisionally this crystalline constituent is referred to as QUARTZINE. Chalcedony forms the chief constituent of agates, and it is also the basis of flint, chert, jasper, carnelian, bloodstone, sard, etc. In many cases it has originated through the deposition of silica derived from the decomposition of silicates. It often occurs as a content of the steam cavities of lavas, sometimes in stalactitic forms. When deposited in horizontal layers it is called ONYX. The onyx of jewellery is produced by allowing the more porous layers of such chalcedony to take up a solution of sugar, which is then blackened by exposure to sulphuric acid.

Chalcocite (*Min.*) A synonym for COPPER GLANCE (*q.v.*)

Chalcography. The art of engraving on copper or brass. *See* ENGRAVING.

Chalcolite (*Min.*) A synonym for COPPER URANITE (*q.v.*)

Chalcopyrites (*Min.*) A synonym for COPPER PYRITES (*q.v.*)

Chalcotrichite (*Min.*) A variety of CUPRITE, the red oxide of copper (*q.v.*)

Chalcotript. One who takes rubbings of "brasses."

Chalice. A name generally given to the cup in which the wine for consecration is placed at the celebration of Holy Communion. Chalices are generally made of either gold or silver, and are often of beautiful design and elaborate workmanship.

Chalk (*Geol.*) A term applied exclusively to the marine limestones of the Upper Cretaceous Rocks of

Britain. Typical chalk is soft and earthy in texture; but this type is confined to the south-east of England. It is a rock of deep water origin, formed from a deposit analogous to the recent foraminiferal oozes. It ranges in thickness from a hundred feet or so to more than ten times that amount. *See also* CALCIUM COMPOUNDS.

—— (*Paint.*) Chalk is often prepared and used for drawing. The name is then generally used in the plural. Applied also to other coloured preparations resembling chalk used in the form of crayons for drawing.

Chalk Drawing. A drawing sketched and filled in with black or coloured crayons.

Chalking (*Dec.*) A condition of white or light paint work in which white lead has been used, and where the paint has a chalky appearance and may be rubbed off with the hand like whitewash. Chalking is common near the sea. It may be prevented by adding zinc white (*q.v.*) to the white lead.

Chalk Line. A long piece of string (on a reel) chalked and drawn tight, for marking straight lines on long pieces of work.

Chalybeate Waters. Waters containing iron in the form of ferrous carbonate held in solution by carbon dioxide. Famous waters of this kind are those at Homburg, Spa, Tunbridge Wells, Harrogate.

Chalybite (*Min.*) Carbonate of iron, also called SIDERITE. It occurs massive or in rhombohedral crystals with curved faces. Usually weathers to a brownish or black colour. It is an important ore of iron, containing 60 per cent. of iron and 36 per cent. carbon dioxide, and often a little calcium, etc. It is often found as a replacement product of limestone, calcium being replaced by iron. Found in Cornwall, Alston Moor, and Cleator Moor in Cumberland, in Saxony, the United States, etc.

Chambered Core (*Foundry*). A CORE (*q.v.*) which is larger at its central portion than its ends.

Chamfer (*Carp., etc.*) A narrow flat surface formed along the edge of a piece of material by removing the sharp edge or ARRIS (*q.v.*)

Chamfer Plane. A plane with guides or fences that can be set so as to form a chamfer of any required width.

Chamfron (*Arm.*) The armour for protecting the forepart of the head of a warhorse.

Chamois (*Zool.*) *Rupricapra tragus* (family, *Bovidæ*). A well known goatlike antelope of Southern Europe. The skin originally furnished CHAMOIS LEATHER (*q.v.*)

Chamois Leather *or* **Wash Leather.** Originally obtained from the chamois; now made from the flesh-split of a sheepskin. It is first limed, split, then put into machines, sprinkled with cod-liver oil, and pummelled, more oil being added at intervals. The skins are then allowed to heat until they turn yellow. They are then washed free from excess of oil. It is largely used in various trades and for domestic purposes for cleaning.

Champlevé (*Enamel*). *See* CLOISONNÉ.

Chancel (*Architect.*) *See* CHOIR.

Chance's Process (*Chem.*) A method of recovering the sulphur from ALKALI WASTE. *See* ALKALI. There are two stages in the reactions of the process. Carbon dioxide is passed through a series of vessels containing the alkali waste suspended in water. In the earlier vessels the carbon dioxide forms carbonate of lime (which can be roasted to yield fresh supplies of carbon dioxide) and sulphuretted hydrogen, thus: $CaS + H_2O + CO_2 = CaCO_3 + SH_2$. This mixture of CO_2 and SH_2 passes into the succeeding vessels, where the SH_2 first forms hydrosulphide of lime, which in turn is decomposed by the carbon dioxide, yielding more sulphuretted hydrogen, thus: (*a*) $CaS + SH_2 = Ca(SH)_2$; (*b*) $Ca(SH)_2 + H_2O + CO_2 = CaCO_3 + 2SH_2$. The sulphuretted hydrogen is collected in gasholders, and utilised either by being completely burned to sulphur dioxide and water, the sulphur dioxide being used for the manufacture of sulphuric acid (*q.v.*), or it is burned in a CLAUS kiln with a supply of air only sufficient to form sulphur (technically known as RECOVERED SULPHUR) and steam, $SH_2 + O = S + H_2O$.

Change Wheels (*Eng.*) The gear wheels employed in a screw-cutting lathe to connect the MANDREL (*q.v.*) and the LEADING SCREW (*q.v.*), in order to produce the required traverse or motion of the slide rest in screw-cutting.

Changing Notes (*Music*). Dissonant notes used in counterpoint, third species, on the second and third beats of a bar, a third apart; one above and the other below the harmony note.

Channel Iron (*Eng.*) Wrought iron bars rolled into a channel-shaped section—*i.e.* forming three sides of a rectangle. Used for girders, roofs, and other structural purposes.

Chantry. A chapel, altar, or other portion of a church endowed for the maintenance of a certain number of priests to sing daily mass, generally for the souls of the founders.

Chape. (1) The metal mounting of a scabbard, particularly that at the tip. (2) The part of a buckle by which it is fastened to the strap.

Chapel (*Typog.*) A meeting or union of the men employed in a printing works, for the purpose of arranging or considering matters affecting themselves or the trade generally. The term is thought to be derived from Caxton's connection with Westminster Abbey. The chairman or spokesman is termed the "Father" of the Chapel.

Chapelle de Fer (*Arm.*) A plain iron helmet with a brim, shaped like a hat. It preceded the BASCINET (*q.v.*)

Chaperon. A small ornamental shield formerly placed on the horses' heads at funerals.

Chaplet *or* **Stud** (*Moulding*). A metal support for a core in the mould.

Characteristic Curves (*Elect. Eng.*) Curves used to show the relation between the CURRENT and the VOLTAGE in dynamos and motors, or the relation of TORQUE (*q.v.*) and SPEED in motors. Much information as to the working of the machine can be obtained from an examination of these curves. *See also* INTERNAL *and* EXTERNAL CHARACTERISTICS.

Charcoal. The residue from the destructive distillation of wood. Wood heated to a high temperature out of contact with the air, in order that the volatile portions may be driven off, yields very nearly pure carbon. Animal matter also yields a very pure carbon. *See* ANIMAL CHARCOAL.

—— (*Paint.*) Sticks of willow charcoal are used as crayons, especially for outline drawing on canvas.

Charcoal Blacking (*Moulding*). Finely ground charcoal for dusting over the surfaces of a mould.

Charcoal Burner (*Dec.*) A portable grate in which charcoal is burned; used in burning off old paint previous to repainting. Is becoming rapidly superseded by the burning-off lamp, but is useful when the old painted surface is flat and of considerable extent.

Charcoal Iron (*Met., etc.*) Iron prepared in a furnace where charcoal is the only fuel. It is the finest and purest variety of iron, and of great value for electrical work, such as transformer cores, armature discs, etc. Now only made in Sweden.

Charcoal Plate (*Eng.*) Thin sheets of iron for the production of tin plate, made from iron refined with charcoal instead of with coke.

Charge (*Her.*) Any heraldic figure depicted on a coat of arms.

—— (*Met.*) The mixture of ore and fuel introduced into a furnace at one time.

—— (*Eng.*) The mixture of air and gas drawn into the cylinder of a gas engine at one stroke.

Charged (*Her.*) A shield is charged when it bears upon its surface some heraldic figure.

Charge, Electrical. A quantity of electricity at rest as distinguished from a current. It is obviously necessary to define "Electricity" with exactness before a "Charge" can be properly defined, and this has scarcely been done up to the present. *See also* ELECTRICITY.

——, **Residual** (*Elect.*) A small charge which may usually be obtained from a LEYDEN JAR or other CONDENSER (*q.v.*) after it has been discharged once. Frequently several residual charges may be obtained in succession, gradually diminishing in amount until too small to be detected.

Chariot (*Archæol.*) The earliest and most primitive form of carriage, consisting generally of a low platform on two wheels and a raised and curving protection in front.

Charles' Law (*Heat*). The volume of all gases varies as their absolute temperature (*q.v.*) if the pressure remain unaltered. Expressed algebraically we get, if V_t and V_o are the volumes at $t°$ and $0°$, respectively (on the Centigrade scale)

$$\frac{V_t}{V_o} = \frac{273 + t}{273}$$

The same law may be expressed by the statement that all gases have (approximately) the same coefficient of expansion, which is about ·00367 of the volume at 0°C.

Charlton White (*Dec.*) A valuable white pigment. *See* ORR'S ZINC WHITE.

Charm (*Archæol.*) *See* AMULET.

Chase (*Build.*) A channel cut in a wall to receive pipes, etc.

—— (*Typog.*) An iron frame for holding type when set up for printing.

Chased. The term is applied to metal or plate embossed and engraved in relief.

Chase Mortise (*Carp. and Join.*) A mortise with a sloping surface to slide a tenon into.

Chaser (*Eng.*) A tool used for cutting screws by hand in the lathe; rarely used except in light work, such as that of opticians, who have to cut fine screws on thin brass tubing. It consists of a flat blade having a number of teeth at the end, which correspond in shape to the grooves between the threads of the screw which it is required to cut. The chaser is moved along the top of the T-REST (*q.v.*) as the work rotates in the lathe. To adjust the rate at which the tool must be moved at first in order to "strike" the thread requires considerable skill; but when the thread has once been started, the finishing process is not very difficult. On this account the chaser is often used for finishing off a thread which has been struck or started by means of STOCKS AND DIES (*q.v.*) or by other mechanical means.

Chase Wedge (*Plumbing, etc.*) A hard wood wedge with a handle. Used for bossing sheet lead.

Chasing (*Eng.*) The process of cutting screws with the CHASER (*q.v.*)

Chasuble (*Cost.*) The chief ecclesiastical vestment, worn by all grades of the clergy. Its original form was a circle, with a hole in the middle for the head to go through; but later the sides were cut away to give freedom to the arms. It is worn over all other vestments.

Chatter (*Eng.*) The waviness produced on the surface of work by vibration of the tool, etc.

Check (*Eng.*) (1) A general name for a joint in which one part fits into another. (2) A disc on which is marked a number assigned to each workman for convenience in timekeeping. The check is left at the timekeeper's office by each man on entering the works.

Checking Motion (*Cotton Weaving*). A mechanism for automatically changing shuttle boxes on a loom, so that shuttles containing different colours of weft may be brought into action to give any desired colouring or check effect. Two distinct systems are in use: (1) Rising and falling boxes. (2) Revolving boxes.

Check Nut *or* **Lock Nut** (*Eng.*) A subsidiary nut screwed on a bolt on top of the ordinary nut to lessen the chance of its working loose.

Check Pattern (*Textiles*). Applied to all patterns consisting of squares, whether of colour or weave.

Check Rail (*Eng.*) A third or subsidiary rail laid on the inner side of a sharp curve on a railway; it just touches the side of the flange of the wheel, and relieves the pressure on the outer rail.

Check Valve (*Eng.*) A valve which prevents the escape of water through the feed pipe of a boiler.

Checky (*Her.*) A shield divided into small squares, generally six rows, sometimes less, the squares being alternately of different tinctures, like a chessboard.

Cheek (*Carp., etc.*) (1) The piece forming the side or jaw of a carpenter's bench screw or vice. (2) A general term for the sides or flanks of various objects, *e.g.* the sides of a tenon.

Cheese (*Foods*). Prepared by curdling, by means of some kind of acid, whole milk, skimmed milk, or milk to which cream has been added. RENNET (*q.v.*), which is obtained from the fourth stomach of the calf, is generally used for the purpose. Cheese is highly nutritious, containing a large amount of proteids and fat. A substance called Annatto is much used for colouring cheese. Cheshire, Cheddar, and double Gloucester cheeses are made from whole milk, and Stilton from a mixture of milk and cream.

Chelsea. The Porcelain Manufactory at Chelsea was established about the year 1745. In 1769 the business and the works were sold to William Duesbury, of Derby, and the manufactory was closed in 1784. During its forty years of existence the Chelsea factory

produced some of the most beautiful of English SOFT PASTE. The porcelain was celebrated for its beautiful glaze, its brilliant colours, fine painting, and rich gilding. The DARK BLUE of Chelsea is especially famous. For marks, *see under* POTTERY AND PORCELAIN.

Chemical Action. When one substance or when a number of substances react under such conditions that one or more new substances are produced, chemical action is said to have taken place. The occurrence of chemical action is dependent on many conditions; *e.g.* (1) *Temperature: e.g.* arsenic pentachloride can be made by passing chlorine into the trichloride below $-25°$; above this the pentachloride cannot exist: (2) *Pressure: e.g.* in Brin's oxygen process (*q.v.*) barium dioxide is formed at 700° under a pressure of two atmospheres, but at the same temperature it is decomposed under a pressure of a few inches of mercury. (3) *Mass: e.g.* when steam is passed over red hot iron the magnetic oxide of iron (Fe_3O_4) is produced and hydrogen liberated; but if hydrogen is passed over heated magnetic oxide, iron and steam are produced. Hence it is clear that for a given mixture of iron and magnetic oxide the direction the reaction will take will depend on the relative masses of steam and hydrogen passing over the mixture. (4) *Light:* equal volumes of hydrogen and chlorine may be kept mixed together in the dark indefinitely, but light brings about union between them. (5) *Catalytic Action. See* CATALYSIS.

Chemical Affinity. *See* AFFINITY, CHEMICAL.

Chemical Engineering. *See* PHYSIO-CHEMICAL ENGINEERING.

Chemical Equations. A chemical equation is a collection of CHEMICAL FORMULÆ (*q.v.*) so arranged as to indicate what substances take part in a reaction and the relative amount of each, and what substances result from the reaction and the relative amount of each; also an equation is always an expression of the principle of the INDESTRUCTIBILITY OF MATTER; *e.g.* $Zn + H_2SO_4 = ZnSO_4 + H_2$ indicates that 65 parts by weight of zinc acted on by 98 parts of sulphuric acid will give 161 parts of zinc sulphate and 2 parts of hydrogen, *i.e.* $(65+98)=(161+2)$: but the equation does not indicate whether heat must be applied; whether heat is evolved or absorbed; that the acid must be dilute; and the zinc in contact with a less easily oxidised element (carbon, iron, copper, or platinum) than itself. Sometimes instead of the sign of equality $=$, the sign $\rightleftarrows$ is used; the latter sign means that the reaction will take place in either sense according to the conditions, *i.e.* the substances denoted by either of the two sides of the equation may combine to produce those on the other. *See* CHEMICAL ACTION.

Chemical Formulæ. A formula is a group of CHEMICAL SYMBOLS (*q.v.*) intended to denote a particular compound; the formula also always stands for one molecule of the compound and therefore a certain relative weight of it, and from the symbols composing the formula we learn what elements are contained in the compound, while from the numbers suffixed to the symbols we learn the number of atoms of each element in a molecule of the compound. A formula which tells us no more than this is an EMPIRICAL FORMULA (*q.v.*) A formula so written as to indicate some of the reactions of formation or decomposition of a compound is called a CONSTITUTIONAL FORMULA. A formula so written as to show the supposed mode of union of all the atoms in the molecule of the compound with each other is called a GRAPHIC FORMULA: *e.g.* H_2SO_4 is the empirical formula for sulphuric acid; $SO_2(OH)_2$ is a constitutional formula, and suggests, among other things, that it is a ***dibasic*** acid. $\begin{matrix}O\\O\end{matrix}\!\!\gg\!S\!<\!\begin{matrix}O-H\\O-H\end{matrix}$ is the graphic formula, and, ignoring spacial considerations, represents the probable mode of union of the atoms in the molecule. *See also* STEREOISOMERISM.

Chemically Formed Rocks. As the term is usually employed these comprise but a small variety of rocks, of which the chief are ROCK SALT, GYPSUM, and DOLOMITE (*q.v.*) Strictly speaking, these should be regarded as MINERALS rather than ROCKS (*q.v.*)

Chemical Pulp (*Paper Manufac.*) Pulp made from wood or other crude cellulose by treatment with caustic soda or bisulphite of lime.

Chemical Symbols. A chemical symbol is a letter, or two letters, used to denote a particular element, and it also denotes one atom, and consequently a particular relative weight of the element. When the symbol, not being joined to other symbols, has a number suffixed to it, the number indicates the number of atoms supposed to be united to form the molecule of the element. Thus H stands for 1 Atom of Hydrogen; H_2 for 1 Molecule of Hydrogen. Hg stands for 1 Atom of Mercury (*Lat.* HYDRARGYRUM) and also for the Molecule of Mercury.

Chenille (*Fabric*). A figured pile fabric, such as tablecovers, curtains, carpets, composed of chenille weft yarn.

—— (*Thread*). This is a woven fringed thread, consisting of a few cotton or foundation threads to which the weft is added in a prescribed order of colouring.

Cheniscus (*Archæol.*) The termination of the stern or prow of Greek and Roman ships which turned up like a goose's neck and frequently had a goose's head carved at the extremity.

Chequers (*Eng., etc.*) (1) Projections of rectangular or diamond shape on plates of metal forming a floor. (2) An openwork arrangement of brickwork through which the hot gases pass in REGENERATIVE FURNACES (*q.v.*)

Cherry. The stone fruit of ***Prunus cerasus*** (order, *Rosaceæ*). *See also* WOODS.

Cherry Coal. *See* COAL.

Cherry Red. A bright red heat (*q.v.*)

Chert (*Geol.*) Usually occurs in the form of concretionary nodules in limestone in the same manner as flint occurs in chalk. Both flint and chert consist fundamentally of a mixture of opaline and cryptocrystalline silica, which is known as CHALCEDONY (*q.v.*); but various impurities are present in both. Those in chert are usually more or less calcareous. Like flint, chert has been formed from weak solutions of silica derived in the first instance from organic structure, such as the siliceous spiculæ of sponges.

Cherub (*Art.*) The head of a beautiful child angel, winged at the neck.

Chessylite (*Min.*) A synonym for AZURITE (*q.v.*), derived from Chessy in France, an important locality for the mineral.

Chest (*Furn.*) A large box or coffer. A very common article of furniture in the middle ages; often made of oak and carved.

Chestnut. *Castanea vulgaris* (order, *Fagaceæ*). The sweet chestnut is of value not only for its edible fruits, but also for the bark, used as a tanning agent. The prepared saplings form the walking sticks known in the trade as "Congo sticks." *See also* WOODS.

Cheval de Frise (*Architect.*) A wood or iron bar from which spikes project. It is frequently used as a means of protection on ground floor window sills and on parapet walls.

Cheviot (*Woollen Manufac.*) A fancy woollen fabric made largely of cheviot and cross-bred wools.

Chevron (*Architect.*) A repeating ornament used on Norman mouldings. It is also known as the ZIGZAG, a name which indicates the form of the ornament.

—— (*Her.*) One of the honourable ordinaries. Formed by two bands one-fifth or one-third the width of the shield, issuing from opposite sides of the base of the shield, and joined rather above the centre.

Chevronel (*Her.*) Diminutive of the chevron.

Chevronny (*Her.*) Lines or bands in form of chevrons dividing a shield. *See* CHEVRON.

Chiaroscuro (*Paint., etc.*) The distribution of light and shade in a picture. (1) The art of establishing a right relation between the parts of a picture which are in light and those which are in shadow, so that a proper degree of form-definition and tone-gradation may be obtained. (2) As a factor in composition, the division of the area of a picture into light and dark surfaces so as to produce an agreeable optical effect and an attractive pictorial pattern. The study of chiaroscuro was based upon the attention given by the great artists of the Renaissance to modelling—*i.e.* to the use of shading, by which a correct impression of variations of projection and recession could be created. The chief masters of chiaroscuro were Rembrandt, Titian, Rubens, and Coreggio. The term was, at one time, applied to pictures in which only two colours were employed, black and white.

Chiastolite (*Min.*) *See* ANDALUSITE.

Chicory (*Foods*). The powdered root of a wild endive (*Cichorium intybus*). Chicory differs from coffee in containing a much larger quantity of sugar, a smaller amount of fat, and no caffeine. Substances used to adulterate coffee may be employed to adulterate chicory. It is generally added to coffee, the mixture being readily detected by examination with the microscope.

Chief (*Her.*) The most honourable ordinary. Placed at the head or top of a shield, and occupying one-third of the field. Formed by one horizontal straight line.

Chiesa (*Music*). *See* CAMERA.

Chili Copper (*Min.*) Ore containing black oxide of copper.

Chili Saltpetre *or* **Caliche** (*Chem.*) Sodium nitrate, found native in Chili and largely exported as a nitrogenous manure and for use in various chemical manufacturing processes.

Chill (*Eng.*) A metallic mould used for CHILLING (*q.v.*)

Chilled (*Paint.*) The varnish on a picture will become clouded and dim when hung in a damp atmosphere; it is then said to be chilled.

Chillies. *See* CAPSICUM.

Chilling (*Eng.*) The hardening of a casting by the use of a mould made of metal. Only certain kinds of cast iron can be successfully chilled; when properly done, a very hard surface is produced.

Chimæra, Chimera (*Myth.*) A fabulous fire-breathing monster composed of various parts of different animals—*viz.* a lion's head with wings, the body of a goat, and the tail of a dragon; or other fantastic combinations.

CHIMÆRA, LYCIAN TERRACOTTA, BRITISH MUSEUM.

Chimney (*Hygiene*). The chimney plays an important part in the ventilation of rooms, being a powerful extractor. When a fire is burning in the grate, a constant current of air passes up the chimney at a rate varying from 3 to 6 ft. per second. Chimneys are often tapped near the ceiling for the insertion of outlet ventilators, such as Boyle's and Arnott's valves. *See* ASPIRATION, VENTILATION BY, *and* VENTILATORS.

Chimney Bar (*Build.*) A bar of iron supporting the brick ring (arch) of a fireplace opening.

Chimney Bond (*Build.*) The BOND or mode of laying the bricks used in the WITHES (*q.v.*) of chimneys; all the bricks are laid as STRETCHERS (*q.v.*)

Chimney Breast (*Build.*) The part of the walls containing the flues, and projecting into the room.

Chimney Shaft (*Build.*) (1) A tall chimney containing one flue. (2) A factory chimney.

Chimney Stack (*Build.*) A chimney containing a number of flues grouped together. In engineering, the term is often applied to a single lofty shaft, though chimney shaft is more correct in this case.

China (*Pot.*) (1) A species of earthenware, semi-transparent, first manufactured by the Chinese. (2) Any imitation of that ware. *See* BÖTTCHER WARE, POTTERY AND PORCELAIN.

China Clay *or* **Kaolin.** A pure form of clay resulting from the prolonged action of subterranean water upon felspars, chiefly those which contain potash. China clay is not simply the result of the weathering of felspar, as is often thought to be the case. It is of considerable importance in the arts not only for the manufacture of china and porcelain, but also as an excellent pigment, requiring only levigation and drying to fit it for use. It is largely employed in the manufacture of paper, as a filler, and as a base in the manufacture of LAKES (*q.v.*) *See also* ALUMINA.

Chinchilla. *Chinchilla lanigera* (family, *Chinchillidæ*). A small squirrel-like rodent belonging to South America. The soft fur is greatly valued.

Chiné (*Silk*). A silk fabric having a printed figure of somewhat hazy, undefined appearance. The silk is first warped and passed through the loom, receiving a few loose picks at intervals of about 12 in.; it is then removed from the loom and printed, after which the HOLDING WEFT (*q.v.*) is removed, and it is again placed in the loom and woven up with TABBY TIE (*q.v.*)

Chinese Paper. Sometimes called India paper, manufactured from the bamboo fibre. It is very fine and of a pale yellow colour.

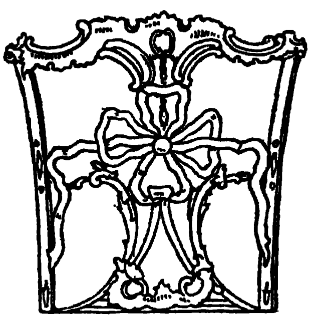
Chinese Red (*Dec.*) Another name for Derby red (*q.v.*)

Chinese Wax. *See* CERYL ALCOHOL.

Chinese White (*Paint.*) A pigment used by artists, consisting wholly of ZINC WHITE (*q.v.*) It is employed both in oil and watercolour painting.

Chippendale Book Plates. This name has been given popularly to the book plates issued between the middle and end of the eighteenth century. They possess the following characteristics, as given in Warren's *Guide*: "A frilling or border of open shellwork is set close to the rounded outer margin of the escutcheon. It is, in fact, a border imitating the pectinated curves and grooves on the margin of the scallop shell." It was studiously asymmetrical, and in latter days it was enriched (some say debased) by the addition of flowers and fruits, or animals, real or mythological. "Chippendale" must not be confounded with "Rocaille" or "Rococo," these being French in character; whereas the first named may be considered national.

Chippendale Furniture. A generic term including originally only chairs, stools, tables, bedsteads, firescreens, and mantelpieces, made by Thomas Chippendale, whose father, of Worcestershire descent, came up to London and settled as a cabinet-maker at No. 60, St. Martin's Lane, excelling as a carver of mirror frames. Thomas Chippendale, "The King of Designers," published in 1754 *The Gentleman and Cabinet Maker's Director*, containing some two hundred designs. While the rococo style of Louis XV. is reflected in his *bombé* fronted commodes, and a few of his chairbacks; while, again, some of the latter are based on Sir William Chambers' Chinese style, Chippendale, nevertheless, founded a style of his own. He gave to his bookcases and clothes presses "different" or "odd" doors, to his tables and moulded chair legs "different" feet. He divided glass, where used, unequally. It is essentially as a designer of chairs that he appeals to us. Actual Chippendale work is in mahogany *without inlay*. The wood was carefully selected and well seasoned. Frets were made by gluing together several thin pieces with the grain running in different directions, thus forming a strip giving immense strength, an object further secured by joining the "splat" of the chair into the framework—a plan since neglected. The choice features of the chairs consist of the carved scroll and interlaced "ribband" backs, and the elaborately sculptured cabriole legs. Equally famous are the "claw and ball" legged chairs, with finely carved "shell and ribband" knee joints. In the armchairs the arms often end in lions' or goats' heads, dolphins or dragons, or curved endive scrollwork. (Fine examples are to be seen at Sir John Soane's Museum, where are eight chairs, the splats inlaid with mother-o'-pearl; Tallow Chandlers' Hall, where are thirty-six chairs, with fluted legs; and South Kensington Museum, which contains some thirty specimens—bedstead, mantelpieces, tables, armchairs, chairs, and firescreens.) Fraudulent arms have been added to many of Chippendale's chairs; these may be recognised by the almost straight designs, which should be finely shaped and gracefully curving. The term Chippendale furniture has now an elastic significance, being applied to any furniture in the peculiar styles of the "Director," or even of the eighteenth century generally. *See also* SHERATON.



CHIPPENDALE CHAIR (BACK).

Chipping Chisel (*Eng.*) A COLD CHISEL (*q.v.*)

Chiretta. *Ophelia chirata* (order, *Gentianaceæ*). The dried plant is imported from India and used in medicine as a bitter tonic.

Chisel. An iron or steel tool with sharp bevelled edge, used in many trades.

Chiton (*Cost.*) The undergarment or vest which was worn both by men and women in ancient Greece.

Chittagong Wood. *See* WOODS.

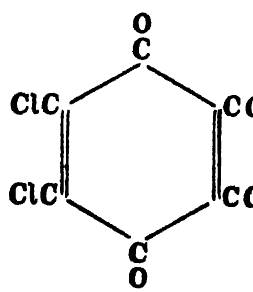
Chladni's Figures (*Sound*). Figures formed on a flat plate when dust, sand, or any fine powder is scattered on it, and it is set in vibration by a violin bow applied to its edge. The dust collects along the lines of least vibration, or NODAL LINES (*q.v.*)

Chlamys (*Cost.*) A cloak worn in ancient Greece. It was oblong in form, and the usual method of wearing it was to arrange one of the shorter sides round the neck, fastening the ends on the right shoulder by means of a clasp, thus allowing the garment to hang down in front and at the back.

Chloral *or* **Trichloracetaldehyde** (*Chem.*), CCl_3CHO. A colourless, oily, pungent-smelling liquid; boils at 97°. It has the reactions of an ALDEHYDE (*q.v.*) Treated with alkalis, it yields chloroform and a formate, $CCl_3CHO + NaOH = CCl_3H + HCOONa$. With water it forms a well crystallised solid, CHLORAL HYDRATE (*q.v.*) It is prepared by passing chlorine into alcohol in the cold at first; then, when the chlorine is less readily absorbed, in heat. The product so obtained is CHLORAL ALCOHOLATE, $CCl_3CH\left\langle\begin{matrix}OH\\OC_2H_5\end{matrix}\right.$, and the operation lasts about a fortnight. This substance is decomposed by sulphuric acid, setting free chloral, which can be separated and purified by distillation.

Chloral Hydrate (*Chem.*), $CCl_3CH\left\langle\begin{matrix}OH\\OH\end{matrix}\right.$. Forms colourless prismatic crystals; has a smell resembling that of a melon; decomposed by heat into its constituents, water and chloral. It is made by adding the proper amount of water to chloral and allowing to crystallise. It is extensively used as a hypnotic (sleep producing) agent, but it is a powerful poison.

Chloranil *or* **Tetrachlorquinone** (*Chem.*) Yellow crystalline plates which sublime without melting. It results from many benzene derivatives, such as phenol and aniline, when they are simultaneously chlorinated and oxidised, as, for example, by hydrochloric acid and potassium chlorate. It is used as an oxidising agent in the preparation of a number of dyes.



CHLORANIL.

Chlorates (*Chem.*) Salts of CHLORIC ACID, $HClO_3$ (*q.v.*) All chlorates are soluble in water; on heating, they evolve oxygen and a trace of chlorine, leaving a

chloride behind. The most important chlorates are those of potassium, sodium, barium. *See* POTASSIUM *and* SODIUM COMPOUNDS.

Chlorhydrins (*Chem.*) Chlorides of dihydric, trihydric, etc., alcohols. Thus ethylene chlorhydrin,

$$\begin{array}{l} CH_2Cl \\ | \\ CH_2OH \end{array}$$

is derived from the dihydric alcohol glycol,

$$\begin{array}{l} CH_2OH \\ | \\ CH_2OH \end{array}$$

by the replacement of one hydroxyl group by chlorine.

Chloric Acid (*Chem.*), $HClO_3$. Is only known in solution in water. The solution has a pungent smell, and is a powerful oxidising agent which sets fire to many organic bodies, such as paper or wood; it may be obtained by adding the calculated quantity of sulphuric acid to a solution of barium chlorate.

Chloride of Lime (*Chem.*) *See* BLEACHING POWDER.

Chlorides (*Chem.*) Are (1) compounds of elements with chlorine; (2) compounds of alcohol radicals (an alcohol minus the OH group or groups) with chlorine; (3) compounds of acid radicals (an acid minus the OH group or groups); (4) compounds of certain other radicals with chlorine. In this article only the first of the above groups is dealt with; the other chlorides will be dealt with individually. The chlorides of the non-metallic elements are gases or liquids, and most of them are decomposed by water, giving acids; they are not salts. The metallic chlorides are liquids, or solids; a few (those of antimony and bismuth, for example) are decomposed by water, giving OXYCHLORIDES, while the rest are not decomposed by water, most of them being dissolved by it—only silver and mercurous chlorides being practically insoluble in water. Chlorides may be obtained: (1) by direct union of the elements; (2) in case of many metals by solution of the metal, its oxide, hydroxide, or carbonate in hydrochloric acid; (3) by double decomposition—*e.g.* the chlorides of lead and silver and mercurous chloride by adding a soluble chloride to a solution of the corresponding nitrate; (4) those of boron, silicon, aluminium, and chromium by passing dry chlorine over a strongly heated mixture of the oxide and carbon.

Chlorine, Cl. Atomic weight, 35·45. A greenish-yellow gas with powerfully irritating smell; very heavy (2·5 times as heavy as air); soluble in water (1 vol. water at the ordinary temperature and pressure dissolves 2·5 vols. of chlorine). Below 10° the saturated solution deposits crystals of a hydrate, $Cl_2 8H_2O$. This gas was the first to be liquefied, as the operation is easily effected. It unites directly with most elements, forming chlorides. Phosphorus and arsenic and some other substances burn in it. Water is decomposed by it under the influence of light, forming hydrochloric and hypochlorous acids. It reacts with most organic compounds, either displacing hydrogen or adding itself directly to the compound, or in a few cases setting free the carbon: *e.g.* acetic acid, CH_3COOH, gives monochloracetic acid, $CH_2ClCOOH$; ethylene, C_2H_4, gives ethylene chloride, $C_2H_4Cl_2$. Some hydrocarbons treated with an excess of chlorine in bright sunlight give carbon and hydrochloric acid gas; such are marsh gas, (CH_4), and ethylene, (C_2H_4), while turpentine gives the same result without sunlight. The gas can be obtained by heating manganese dioxide with hydrochloric acid or any other peroxide; also by heating potassium permanganate or dichromate with the same acid; also by acting on bleaching powder (*q.v.*) with an acid, and in many other ways. *See* DEACON'S PROCESS. The principal uses of chlorine are: (1) In bleaching (*q.v.*) it bleaches in virtue of its action on water: $Cl_2 + H_2O = 2HCl + O$, the oxygen liberated being the effective agent—oxidising the colour to a colourless compound. (2) In the extraction of gold. (3) In the preparation of many important organic compounds. *See* CHLORAL HYDRATE. (4) As a disinfectant. It is best applied for room disinfection by washing the walls with a 1 per cent. solution; the washing should be repeated two or three times. A preparation known as "Chloros," which contains 10 per cent. of chlorine, is also a good disinfectant.

Chlorine Carriers (*Chem.*) Iodine, the pentachlorides of antimony and molybdenum, ferric chloride, all in dry state, have the power of greatly accelerating the action of chlorine on certain carbon compounds; they are called chlorine carriers. Carbon disulphide is readily converted into the tetrachloride by chlorine in presence of antimony pentasulphide. Nitrobenzene readily gives metachlornitrobenzene when treated with chlorine in presence of ferric chloride; without the ferric chloride there is no action at all.

Chlorine Monoxide (*Chem.*), Cl_2O. A yellow gas with irritating smell: explodes on heating, also on contact with organic matter such as sugar or turpentine. Its solution in water forms HYPOCHLOROUS ACID (*q.v.*) It is obtained by passing chlorine over cold dry yellow mercuric oxide.

Chlorine Peroxide (*Chem.*), ClO_2. A yellow gas with perfectly characteristic smell; readily explodes on heating and on contact with organic matter; very soluble in water. Obtained by very cautiously heating potassium chlorate with sulphuric acid; also obtained, mixed with chlorine, by the action of hydrochloric acid on potassium chlorate.

Chlorite Schist (*Geol.*) Usually a dynamically formed rock whose parent mass was one containing a large proportion of one or more of the FERRO-MAGNESIAN SILICATES (generally an amphibole). Percolating waters have changed the composition of these latter, and the differential movement of parts of the rock mass caused by earth-creep has given rise to the SCHISTOSE STRUCTURE (*q.v.*)

Chlorite Slate (*Geol.*) Slates coloured pale green by iron in the ferrous condition are often spoken of under this name. Most of the rock now remaining which has been called "Chlorite Slate" is really Chlorite Schist (*q.v.*)

Chloro Derivatives (*Chem.*) These are the chlorine substitution products of organic compounds, *e.g.* CHLOROBENZENE, C_6H_5Cl, is derived from benzene by replacement of an atom of hydrogen by an atom of chlorine. *See* BROMO DERIVATIVES.

Chloroform *or* **Trichlormethane** (*Chem.*), $CHCl_3$. A heavy, colourless, sweet-smelling liquid; boils at 61·5°; is slightly soluble in water; an excellent solvent for many organic substances. It is a powerful anæsthetic when inhaled. In presence of air and light it is oxidised to CARBONYL CHLORIDE (*q.v.*), a dangerous gas to inhale; 1 per cent. of alcohol preserves it. Heated with alcoholic potash it yields potassium formate; with alcoholic potash and an amine (*e.g.* aniline) it yields the nauseous-smelling ISOCYANIDES (*q.v.*) This reaction serves as a test. It is obtained from CHLORAL (*q.v.*); also by distilling a mixture of bleaching powder, water and alcohol on a water bath.

Chlorophyll (*Botany*). The green colouring matter of plants. The pigment can be extracted from various leaves, and is used as a delicate colouring agent for perfumes, essences, etc.

Chloroplastid (*Botany*). The agent in assimilation or PHOTO-SYNTHESIS (*q.v.*) It is a protoplasmic body holding a green pigment, chlorophyll (*q.v.*), which by its action upon light supplies the energy needed for assimilation.

Checking (*Mining*). *See* CHOCKS.

Chocks (*Mining*). Supports loosely built in to support the roof of a seam when the coal is removed. The process is called CHOCKING.

Choir (*Architect.*) The part of a church to the east of the nave, and often separated from it by a screen. It is used by the clergy and others assisting in the services, and is also known as the CHANCEL. *See* NAVE.

Choir Organ (*Music*). That part of an organ chiefly used in accompanying the choir in the softer parts of the service, and connected with the lowest keyboard of three-manual organs.

Choke Damp (*Mining*). CARBONIC ACID GAS (*q.v.*)

Choking Coils (*Elect. Eng.*) A coil of insulated wire of low resistance, wound on a core of laminated iron or iron wire; it possesses a large impedance (*q.v.*), and is therefore often called an IMPEDANCE COIL. It is joined up in series in an alternating current circuit to prevent too large a current from flowing through the circuit. These coils serve the same purpose as a resistance does in a continuous current circuit, but do not cause any appreciable waste of power if they are properly designed. The size of the core and the number of turns on the coil are determined in a manner similar to that adopted in designing a TRANSFORMER (*q.v.*)

Cholesterine (*Chem.*), $C_{27}H_{45}OH$. Forms shining crystalline plates; soluble in alcohol, ether, and chloroform. Said to be an alcohol. It occurs in nervous tissue and in bile; gallstones are often composed nearly entirely of it. Its chloroform solution, shaken with concentrated sulphuric acid, turns red, then violet, while the acid acquires a green fluorescence.

Choline (*Chem.*), $N\begin{cases}CH_2CH_2OH\\CH_3\\CH_3\\CH_3\\OH\end{cases}$

(*Oxyethyltrimethylammonium hydroxide*). A thick liquid (crystallises with difficulty), very soluble in water; it has a bitter taste. It is a powerful alkali, forming salts with acids—even carbonic acid. It is a PTOMAINE (*q.v.*), and is found in decaying corpses, also in pure cultures of the cholera bacillus. It is not very poisonous, being similar in its action to MUSCARINE (*q.v.*), but in much smaller degree. It is a splitting product of lecithin, a substance found in all nervous tissue. It has been made artificially by the union of ethylene chlorhydrin (*see* CHLORHYDRINS) and TRIMETHYLAMINE (*q.v.*)

Chopine (*Cost.*) A high wooden clog or patten worn on the feet. Chopines were worn in England during the fifteenth and sixteenth centuries, being introduced from Venice, where, among ladies, the height was regulated by the rank of the wearer.

Choragic Monument (*Architect.*) A monument erected in honour of the victorious Choragus (*q.v.*) in a Greek choral competition. The Choragic monument of Lysicrates at Athens is a fine example.

Choragium (*Archæol.*) The apartment where the chorus was trained in a Greek or Roman theatre, or the space where the choral dance was performed.

Choragus, Choregus (*Archæol.*) (1) In ancient Greece the leader or superintendent of the chorus. (2) The title of a functionary connected with musical studies in the University of Oxford.

Chord (*Geom.*) A straight line which joins the extremities of an arc of a circle or other curve.

—— (*Music*). Two or more notes sounded together.

Chorus. In ancient Greece a band of singers and dancers who performed at festivals and in the drama.

Chromate of Lead (*Min.*) A synonym for CROCOISITE (*q.v.*)

Chromates (*Chem.*) Salts of chromic acid, (H_2CrO_4). *See* POTASSIUM CHROMATE *and* DICHROMATE, *under* POTASSIUM COMPOUNDS; *and* LEAD CHROMATE, *under* LEAD COMPOUNDS.

Chromatic Aberration (*Light*). Since the focal length of a lens depends on the index of refraction (*q.v.*) of the glass, it follows that there will in general be different foci for light of different wave lengths. Thus an ordinary simple lens will have a focus for violet rays which may be separated by a considerable distance from the focus of the red rays, while the foci of the remaining colours of the spectrum will be between these two points. This dispersion or separation of colours is termed chromatic aberration. It may be corrected by combining two or more lenses, forming an ACHROMATIC LENS or COMBINATION. The commonest form consists of a convex lens of crown glass and a concave lens of flint glass placed in contact. Such a combination can be made achromatic for two colours only—*e.g.* it may bring red and violet rays to a common focus; but if we required rays of a third colour to be brought to the same focus, we should require a third lens. In practice, lenses required for visual purposes are usually achromatised for rays in the orange-red and the green-blue parts of the spectrum; while lenses required for photography are achromatised for rays near the violet end.

Chromatic Chord (*Music*). A chord having one or more notes foreign to the diatonic scale.

Chromatic Notes (*Music*). Those altered by accidentals.

Chromatics. The theory and science of colours; the branch of optics that treats of the properties of the colours of light and of natural bodies. *See* COLOUR.

Chromatic Scale (*Music*). Consisting entirely of semitones.

Chrome Alum (*Chem.*) *See* CHROMIUM COMPOUNDS.

Chrome Green (*Dec.*) A permanent green consisting of oxide of chromium. *See also* CHROMIUM COMPOUNDS.

Chrome Iron Ore. *See* POTASSIUM DICHROMATE, *under* POTASSIUM COMPOUNDS.

Chrome Leather. Leather of all kinds which has been tanned with chrome salts instead of with vegetable tanning materials.

Chrome Ochre (*Min.*) A clay containing a mixture of the sesqui-oxides of chromium, and occurring in association with CHROMITE (*q.v.*), from the decomposition of which it probably results.

Chrome Red. *See* LEAD CHROMATE, *under* LEAD COMPOUNDS *and* DERBY RED.

Chrome Yellow (*Dec.*) The most useful yellow of the decorator. It consists of chromate of lead, and is made in various shades, such as "primrose" (the lightest), "lemon," "middle," "deep," etc. May be mixed with other pigments, excepting those containing sulphur, such as ultramarine (*q.v.*) and cadmium yellow (*q.v.*)

Chromite (*Min.*) A chromate of iron, aluminium, and magnesium $(FeO,MgO)(Cr_2O_3, Al_2O_3)$, containing 40 to 64 per cent. of Cr_2O_3: cubic: occurring in iron-black octahedra in serpentine, a metamorphosed ultrabasic rock. The PORPHYR VERDE ANTIQUE owes its green colour to disseminated chromite. Found in the Urals, United States, etc.

Chromium, Cr. Atomic weight, 52·1. A hard white metal: less fusible than platinum: oxidised in moist air: dissolved by hot dilute hydrochloric and sulphuric acids, forming corresponding chromous salts: slowly attacked by dilute nitric acid: obtained by heating chromic oxide with carbon in the electric furnace, and again heating the product in succession with chromic oxide, with quick lime, and finally with the double oxide of chromium and calcium obtained in the last process as a by-product; also by heating chromic oxide with aluminium powder. *See* GOLDSCHMIDT'S PROCESS. Alloyed with iron (1·2 to 1·5 per cent. Cr) it forms CHROMIUM STEEL, used in making projectiles. Chromium does not occur native; it exists in combination in CHROMITE (*q.v.*), CHROME OCHRE, a complex silicate, and SELWYNITE, a similar mineral found in Australia, and in some chromates as CROCOISITE (*q.v.*)

Chromium Compounds (*Chem.*) Chromium acts as a basic element, forming two classes of salts (chromous salts and chromic salts), and also as an acidic element forming an acid oxide (chromium trioxide). The CHROMOUS SALTS resemble the ferrous salts in constitution and behaviour; *e.g.* they are strong reducing agents, and dissolve nitric oxide. CHROMIC OXIDE, Cr_2O_3, is a dull green powder when made by heating the hydroxide or a mixture of potassium dichromate and ammonium chloride; a brighter green when made by heating mercurous chromate. It is a basic oxide. Heated with alkalies in presence of air or an oxidising agent, it gives chromates, $2K_2CO_3 + Cr_2O_3 + 3O = 2K_2CrO_4 + 2CO_2$. Used as a pigment, chrome green, and in colouring glass and porcelain. CHROMIC HYDROXIDE: A grey-green precipitate formed by adding an alkali or alkaline sulphide to a soluble chromic salt. CHROMIC CHLORIDE, $CrCl_3$: A peach blossom coloured salt when obtained by passing chlorine over heated mixture of chromic oxide and carbon, insoluble in water; a green crystalline mass when obtained by dissolving the hydroxide in hydrochloric acid and crystallising the solution. CHROMIC SULPHATE: The hydroxide is dissolved in sulphuric acid in the cold, and solution on standing deposits violet blue crystals, which, heated with sulphuric acid, give red anhydrous chromic sulphate, $Cr_2(SO_4)_3$. The violet solution turns green on heating, owing to formation of basic salts. It forms alums (*q.v.*) CHROME ALUM, $K_2SO_4Cr_2(SO_4)_3 24H_2O$: Dark purple octahedra, red by transmitted light. Solution is dichroic (red green), and turns green, like the sulphate, on heating. Obtained by reduction of a mixture of potassium dichromate and sulphuric acid by sulphur dioxide or alcohol. Used in dyeing and calico printing. CHROMIC TRIOXIDE, CrO_3: Lustrous red prisms, very soluble in water; the solution behaves as an acid, chromic acid, $CrO_3 + H_2O = H_2CrO_4$. It is a powerful oxidising agent. Obtained by adding sulphuric acid to cold concentrated solution of potassium dichromate. CHROMYL CHLORIDE, CrO_2Cl_2: A dark red liquid boiling at 118°. With water forms chromic and hydrochloric acids. It converts methyl groups of aromatic hydrocarbons into aldehyde groups (Etard's reaction); *e.g.* toluene (*q.v.*) to benzaldehyde (*q.v.*)

Chromo Lithography. *See* LITHOGRAPHY.

Chromo Sensitive Material (*Photo.*) *See* PHOTOGRAPHY IN COLOURS.

Chromo Xylography. *See* ENGRAVING: CHROMO XYLOGRAPHY.

Chromyl Chloride. *See* CHROMIUM COMPOUNDS.

Chronograph. A registering timepiece, usually having a start, stop, and flyback seconds hand.

Chronoisothermal Curves (*Meteorol.*) Curves showing the hour of the day at which the average temperature at some given point on the earth's surface has the same value at different times of the year.

Chronometer. A finely made timepiece, with a balance wheel specially adjusted to ensure the keeping of correct time when the temperature varies. It also has a "dedent" escapement. For marine use the instrument is suspended in "gimbals," or slings, to preserve it from vibration and to keep it, as far as possible, horizontal.

Chryselephantine (*Archæol.*) A term applied to works of sculpture overlaid with ivory and gold, *e.g.* the statue of Athene by Pheidias.

Chrysene (*Chem.*), $\begin{array}{l} C_6H_4 - CH \\ \vert \\ C_1 \end{array}$

Forms white leafy crystals with violet fluorescence: melts at 250°. It occurs in the highest boiling portions of coal-tar.

Chrysoberyl (*Min.*) Beryllium aluminate, $BeO.Al_2O_3$. Alumina = 80·2, berylla = 19·8 per cent. It occurs in rhombic prisms of various shades of green. Its hardness = 8·5. It is cut as a gem. Found in the Mourne Mountains in Ireland, in Ceylon, Brazil, the Urals, United States, etc.

Chrysocolla (*Min.*) A hydrous silicate of copper, $CuSiO_3 . 2H_2O$. Oxide of copper = 28 to 45, silica = 26 to 40, water = 16 to 31 per cent. As an ore it only yields up to about 10 per cent. of copper. It is used as an ornamental stone. The colour varies in different shades of blue and green, perhaps due to colouring by impurities. Found in Cumberland, Westmoreland, Cornwall, Dumfriesshire, Saxony, Australia, etc.

Chrysoidine (*Chem.*) $C_6H_5-N=N-C_6H_3(NH_2)_2$ HCl (1 : 2 : 4). Shining black crystals, greenish by reflected light. It is a dye used for orange shades on wool, silk, and cotton mordanted with tannin. Prepared by action of diazobenzene chloride (*see* 'DIAZO' COMPOUNDS) on metaphenylene diamine (*q.v.*) *See also* DYES AND DYEING.

Chrysolite (*Min.*) A silicate of magnesium and iron, $2(MgFe)O . SiO_2$. Rhombic. Colour, pale green and transparent to dark green and translucent. The term is rather confined to the transparent variety, OLIVINE being used as a more general term. Olivine

is a common constituent of basic eruptive rocks. Chrysolite is cut as a gem. The best chrysolite comes from the Levant.

Chrysophenin. *See* DYES AND DYEING.

Chrysoprase (*Min.*) A green variety of CHALCEDONY (*q.v.*), semitranslucent; coloured by nickel oxide. It is cut for jewellery, and is supposed to bring the wearer good luck.

Chrysotile (*Min.*) A fine fibrous variety of SERPENTINE (*q.v.*), usually of rich yellow green colour, and of a silky lustre. It is sometimes used as an ornamental stone.

Chuck. (*Eng.*) A device for holding work on the mandrel of a lathe or for holding small drills. There are very many forms. *See* CUP CHUCK, DIE CHUCK, SELF-CENTRING CHUCK, *etc.*

Chuffs (*Build.*) Bricks full of cracks, caused by rain falling on them when being burnt.

Church Bells (*Her.*) Represented in perspective, the clapper visible below the rim of the bell and the shank visible at the top.

Chute *or* **Shoot** (*Mining*). An inclined shaft through which minerals are allowed to fall to a lower level: the term is also applied to channels carrying water, etc.

Chyle (*Zoology*). The milky fluid, containing fats, found in the lacteal vessels in the walls of the small intestine. *See* VILLI. The fats are formed from the fatty bodies absorbed from the CHYME.

Chyme (*Zoology*). The semi-liquid mass of food, mixed with gastric juice and peptones, after passing through the stomach.

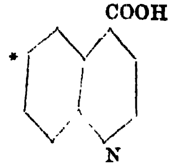
Ciborium. (1) A chalice or cup with a cover for holding the consecrated bread or host. (2) The PYX (*q.v.*) (3) The tabernacle for holding the pyx. (4) A portable altar. (5) A receptacle for relics. *See also* BALDACHINO.

C.I.F. (*Cotton*). A system of direct shipment to spinner by which the purchaser is allowed 6 per cent. and free Carriage, Insurance, and Freight.

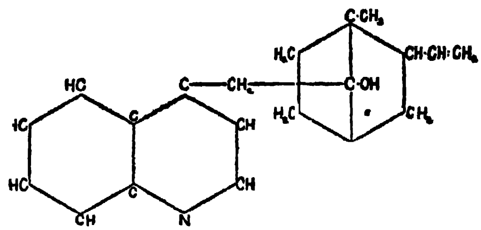
Cimbalo. *See* MUSICAL INSTRUMENTS: STRING.

Cinchona (*Botany*). A genus of the order *Rubiaceæ*, of economic importance as the source of PERUVIAN BARK. *C. succiruba* produces the red bark; *C. calisaya*, the yellow variety; *C. officinalis*, the brown variety. *See also* QUININE.

Cinchonine (*Chem.*) An alkaloid closely related chemically to quinine (*see* QUININE), but not having its valuable medicinal properties: it differs also from it in not giving a green colour with chlorine water and ammonia and in not yielding fluorescent salts. It occurs in cinchona bark along with quinine and many related alkaloids (about thirty); and it is separated from quinine by making use of the facts: (1) that its sulphate is more soluble than that of quinine; (2) that the alkaloid is less soluble in alcohol and in ether than quinine. It is a white crystalline solid (prisms); begins to sublime at 220° and melts at 254°: bitter taste: very slightly soluble in water. Unlike the majority of alkaloids, its alcoholic solution is dextrorotatory. It is a strong diacid base, and so forms two series of salts. It is easily transformed into a number of isomeric alkaloids; *e.g.* by boiling it with acetic acid it yields a far more poisonous isomeric alkaloid, cinchotoxin or cinchonicin. The following facts are very important in relation to the constitution of this alkaloid and the closely related quinine (methoxy-cinchonine). It is a ditertiary base. *See* TERTIARY BASES. It is an alcohol, as it unites with acid chlorides to form esters. It is an unsaturated compound (*q.v.*), as it adds on two atoms of bromine. It is a quinoline derivative, as on oxidation with chromic acid it yields γ-quinoline carboxylic acid. By a somewhat complex series of reactions cinchonine has been converted into lepidine (γ-methylquinoline) and a substance, meroquinine, which is a pyridine derivative. On these and other grounds the following formula has been suggested for cinchonine:



Cinchonic acid.



Quinine only differs from cinchonine chemically in having a methoxy group, (OCH_3), instead of H, in the places marked with an asterisk in the above formulæ.

Cinctures (*Architect.*) The annulets on the shaft of a column immediately above the base and below the astragal of the capital. The projecting blocks which sometimes form part of the shaft of a column are also known as cinctures.

Cinder Pig (*Metallurgy*). A poor variety of pig iron obtained by resmelting slags which are somewhat rich in iron.

Cinder Tap (*Met.*) The slag from puddling or re-heating furnaces.

Cinder Tub (*Met.*) A shallow iron truck with movable sides, into which blast furnace slag is run.

Cinematograph. The common name for apparatus for the production and exhibition in *rapid sequence* of a series of photographs of moving objects, creating the illusion known as "living pictures" or "animated photographs." Special forms of the apparatus are given other names for trade purposes, as the BIOGRAPH, which is probably the largest and best manufactured at present. The illusion depends on persistence of vision, each single picture remaining impressed on the retina till the following one appears. The instrument is a development of the Zoëtrope and was made possible by the introduction of flexible film into photography, to take the place of glass plates. Edison perceived the possibility of moving a long narrow strip of sensitive film along the focal plane of a small camera, and automatically exposing it to the image formed there by the lens, and after some experiment he introduced his "Kinetiscope," about 1894. His method of moving the film is still employed, but in other respects the apparatus has been greatly improved. The instrument consists of a small camera provided with light-tight chambers above and below, and with mechanism for moving the film and working the shutter of the lens. The long strip of film wound on a drum is placed in one chamber, one end is passed into the camera and along its focal plane to

an empty drum in the other chamber, the sensitive surface, of course, facing the lens. On turning a handle, the mechanism pulls down a portion of the film exactly the size for the picture, opens the shutter of the lens, and closes it again, and goes on repeating these operations in the same order at the rate of from twenty-five to fifty times a second, the film remaining stationary for the fraction of a second required for the exposure of each separate picture. In the larger and heavier instruments the motive power is supplied by an electric motor. The film thus exposed in the camera gives a series of very small negative pictures when developed, and from it a positive film must be printed for exhibition. These films are pulled through the apparatus by means of perforations along the edge, and the perforations in the positive must exactly coincide with those in the negative film. The same or similar apparatus, fixed in front of the condenser of a powerful magic lantern, is used for exhibition and worked in the same way. When exhibited, the same pictures are sometimes magnified nearly 15,000 times, and 1,200 pictures are stopped and moved on in a minute. In order to give a correct record of the scene depicted, the pictures should be exhibited at the same speed as they were taken, but they are usually exhibited somewhat quicker.

Cinerary Urn (*Archæol.*) A sepulchral urn for holding the ashes of bodies which have been burned. There are many examples in the British Museum.

Cinnabar (*Min.*) Sulphide of mercury, HgS. Mercury = 86·2, sulphur = 13·8 per cent. It occurs in deep red highly refractile rhombohedral crystals, and massive in darker red shaly masses. It is the chief source of mercury. The pigment VERMILION is prepared from it. Found in Idria, Almaden, etc., in Spain; Hungary, Mexico, Peru, California, Japan, etc.

Cinnamic Acid (*Chem.*), $C_6H_5CH:CH.COOH$. β-phenylacrylic acid. White needles or prisms: melts at 133°: slightly soluble in cold, readily in hot water. It is an unsaturated compound (*q.v.*), and takes up two atoms of bromine: formerly important in the synthesis of indigo: occurs in storax and a number of balsams: obtained artificially by acting upon benzaldehyde (*q.v.*) with sodium acetate and acetic anhydride (Perkin's reaction), $C_6H_5CHO + CH_3COONa = C_6H_5CH:CH.COONa + H_2O$. There are two unstable modifications of it—allocinnamic and isocinnamic acids. *See* STEREOISOMERISM.

Cinnamon. The drug and spice is the dried inner portion of the bark of the young branches of *Cinnamomum zeylanicum* (order, *Lauraceæ*).

Cinnamon Stone (*Min.*) One of the calcium Aluminium GARNETS (*q.v.*), often also called HYACINTH; it is an orthosilicate of calcium and aluminium, with the iron in the ferric state. The exact composition varies. The colour is yellow to brown. The hardness is slightly greater than that of quartz. Used as jewellery. It crystallises in forms of the cubic system. Localities are: Aberdeenshire, Wicklow, Ceylon, etc.

Cinquecento. Literally 500, but used as an abbreviation of "mille cinquecento," 1500. A term applied in Italy to the sixteenth century, the period when art revived and classical influence was paramount. It is also applied to decorative art and architecture characterised by the reversion to classical forms that commenced about 1500. The term is often applied incorrectly to ornament of the sixteenth century in general.

Cinquefoil (*Architect.*) An opening in Gothic tracery formed with five foils or spaces between cusps. *See also* FOILS, CUSPS, TREFOIL, QUATREFOIL, *and* MULTIFOIL.

Cipher. (1) The symbol 0, which denotes zero. (2) A cryptographic mark or device. Sometimes it takes the form of a monogram.

Cipolin. A white marble with green streaks.

Cippus (*Archæol.*) A small column or pedestal, generally rectangular, forming a sepulchral monument. It either contained the ashes of the deceased or marked the place of burial, and frequently bore an inscription. Cippi were also employed by the ancients as memorials of remarkable events, and as landmarks.

Circle. In geometry, a plane figure bounded by a single curved line, called the circumference, every point on which is equidistant from a certain point within, termed the CENTRE.

—— (*Lace Manufac.*) That portion of a twist lace machine where all the most delicate parts of the mechanism are situate. The centre of the circle is the point where the formation of the lace becomes perceptible. All the movements of the threads necessary for its formation take place in the lower portion of its circumference.

Circle of Curvature. A circle drawn from the centre of curvature of a curve, with radius equal to the length of the normal from that point to the curve, is called the "Circle of Curvature" of the curve for the point where it is cut by the normal. This circle of curvature may be regarded as the circle whose curvature coincides with that of the curve at the point where they touch.

Circle of Reference. *See* HARMONIC MOTION.

Circle on Circle (*Carp. and Join., etc.*) A piece of work which is curved both in plan and elevation: work of double curvature. A door or window with a round (arched) top, situate in a round building, is an example.

Circular Measure. The circular measure of an angle is the ratio of the arc of a circle, bounded by the two lines forming the angle, and having its centre at the apex, to the radius with which the arc is described. The circular measure of an angle of 180° is π, of 90°, $\frac{\pi}{2}$, and an angle whose circular measure is unity contains $\frac{180°}{\pi}$, or 57·296° very nearly. This angle is termed a RADIAN.

Circular Mitre (*Carp. and Join.*) The intersection of a straight and curved moulding of the same section.

Circular Plane (*Carp., Pattern Making*). A plane for working concave or convex surfaces. A modern form, made of iron, has a thin steel sole which can be bent into a circular arc of any required radius (within certain limits), to work on both concave and convex surfaces.

Circular Polarisation (*Light*) *See* POLARISATION.

Circular Saw. A saw in the form of a steel disc: used for *rapid* and heavy sawing in woodworking; also for metal, in which case the saw is made of much thicker steel and the teeth are formed more like the teeth of a milling cutter (*q.v.*)

Circulating Pump (*Eng.*) The pump used to keep cold water flowing through the CONDENSER (*q.v.*) of a steam or other engine.

Circulation in Boilers, etc. (*Eng.*) The movement of water in boilers, etc., due to connection currents set up by the fall in density of the heated water. It is promoted in boilers by a proper arrangement of water tubes and by keeping the water as much as possible above the heating surfaces. In condensers, pumps are necessary to keep up the circulation.

Circulation of Water (*Motor Cars*). In petrol cars a flow of water from a tank is maintained round the water jacket of the cylinder (*q.v.*) through a radiator or condenser (*q.v.*), the water returning to the tank. This keeps the engine cool, and prevents injury to the cylinder, as well as loss of power, which always occurs if the cylinder become overheated.

Circumferenter (*Surveying*). A form of MINERS' DIAL (*q.v.*) adapted for surveying with the fixed or "fast" compass needle. Also called the ROCK DIAL. It consists of a graduated horizontal circle, provided with a vernier and sights, and a compass needle suspended at the centre of the circle.

Circumflex Accent (*Typog.*) A mark placed over a letter thus, ê.

Circumpolar Star (*Astron.*) A star always above the horizon, *i.e.* one whose angular distance from the celestial pole is less than the terrestrial latitude of the place of observation.

Circus (*Archæol.*) A large oblong building used by the Romans for horse racing, chariot racing, gladiatorial contests, etc., which took place in the arena. Around the building rose tiers of seats for the spectators. The Romans seem to have established circuses wherever they settled.

Cire Perdue. *See* LOST WAX.

Cirque (*Geol.*) A name usually given to some geographical features occurring near the heads of valleys in districts that have been heavily glaciated. The features in question are shaped like a bowl which has been cut in halves from top to bottom. In some few cases such a feature may really be due to the conjoined action of several adjacent streams; but it is now recognised as being more generally due to the erosive action of ice, to which local circumstances have imparted a slow rotatory or eddying movement.

Cirro-Cumulus (*Meteorol.*) *See* CLOUDS.

Cirrus (*Meteorol.*) *See* CLOUDS.

Cissing (*Dec.*) A fault in a varnished surface in which small dull spots appear. Usually caused either by minute holes or grease spots. Remedy: thoroughly clean and rub down surface and re-varnish.

Cist *or* **Kist** (*Archæol.*) A stone coffin of prehistoric times formed by two parallel rows of slabs placed on edge, with one or more slabs placed horizontally across them. Sometimes the cist was excavated in the solid rock or formed in a tree trunk. *See also* CISTA.

Cista (*Archæol.*) The name given to a small box containing sacred objects, carried at the festivals of Demeter and Dionysus. (2) The ballot box used in the Roman comitia.

Cistern Barometer. *See* BAROMETER.

Cistern Pump. *See* FORCE PUMP.

Cisterns (*Hygiene, etc.*) Where the water supply of a town is on the intermittent principle, cisterns are necessary for the storage of water. They should be fixed in a well ventilated place, regularly cleansed, properly covered, and constructed of a material that will not impart any impurity to the water. It is extremely important to see that no communication exists between the cistern supplying the water closet and the storage cistern.

Cithara. An ancient musical instrument with from seven to eleven strings, somewhat like the lyre in shape. The modern zither is also derived from it, and preserves much the same form.

Citric Acid (*Chem.*), $CH_2COOH.COHCOOH.CH_2COOH$. Large colourless crystals: melts at 153°: readily soluble in water and in alcohol. It occurs free in a large number of fruits, and is obtained from lemon juice by precipitating the citric acid in it as calcium citrate (the precipitate only forms on heating), and decomposing this salt with sulphuric acid. This acid has been prepared artificially. It is much used in making effervescing drinks and to impart an acid flavour (*e.g.* to jellies).

Citrine (*Min.*) Quartz of a clear yellow colour; also called YELLOW TOPAZ.

Citron. *See* CITRUS.

Citronella Oil. An oil used in perfumery, distilled from a species of grass, *Andropogon nardus* (order, *Gramineæ*), extensively grown in Singapore.

Citrus (*Botany*). A genus of the order *Rutaceæ*, noted for the economic importance of its species and varieties. *C. medica* is the citron, whose variety *Limonum* is the lemon, *Limetta*, the sweet lime. *C. aurantium*, the orange, has two varieties—*Bergamia*, the Bergamot, and *Bigaradia*, the Seville orange.

City Solder. Solder stamped by the Worshipful Company of Plumbers.

Civil Engineering. The branch of engineering dealing with railways, roads, docks, harbours, waterworks, and many other branches of construction, but excluding mechanical and electrical appliances.

Cl (*Chem.*) Symbol for CHLORINE (*q.v.*)

Clack *or* **Clack Valve** (*Eng.*) The flap or hinged valve of a suction pump.

Clairecolle *or* **Clearcole** (*Dec.*) An undercoat of size employed on plaster surfaces to stop suction and form a ground for distemper. Made from glue, size, or concentrated size powder mixed with whiting and water.

Clam. Clamp (*Eng.*) Pieces of wood or soft metal (such as lead) fitted to the jaws of a vice for holding polished or delicate objects without injury.

Clamp (*Brickmaking*). A clamp is a stack of raw bricks, with cinders intermixed, to assist in their complete burning. *See also* BRICKS.

—— (*Eng., Carp., etc.*) An appliance used for gripping a piece of work in order to force its parts into close contact; the requisite pressure is usually applied by means of a screw.

Clamp Bricks. Bricks that have been burnt in a clamp; they are also known as STOCK BRICKS. *See also* BRICKS.

Clamping Screw (*Eng.*) Any screw for holding a detachable tool or part of a machine in place.

Clarendon (*Typog.*) A bold-faced condensed type, generally used in dictionaries. The TERMS in this work are printed in clarendon type.

Clarinet *or* **Clarionet.** *See* MUSICAL INSTRUMENTS: WIND (WOOD).

Clark Cell (*Elect.*) The best known form of "Standard Cell" (*q.v.*) Its positive pole is a platinum wire dipping into mercury. Above the mercury is a paste of mercurous sulphate; on this floats a saturated solution of zinc sulphate, in which dips a rod of zinc forming the negative pole. The E.M.F. is 1·434 volts at 15° C., falling slightly as the temperature rises.

Clark's Process. The object of this process is to soften water. The hardness of water is due to the presence of salts of lime and magnesia. In Clark's Process lime water is added, and combines with the carbon dioxide; the bi-carbonate of lime is thus rendered insoluble and precipitated. The precipitate carries down with it any suspended matters present in the water. It is only efficacious in removing what is called "temporary hardness." *See also* CALCIUM COMPOUNDS.

Clasp (*Bind.*) A catch formerly used for holding the covers of a book together when closed.

Clasp Nail. A nail used by pattern makers. It has projections from the head which enter the wood as well as the stem or shank of the nail. These projections give the nail a greater hold on the wood than a common nail would afford.

Clasp Nut (*Eng.*) The nut in a slide rest which engages the leading screw (*q.v.*) It can be disengaged at will, as it is cut through longitudinally, so that the two halves can be separated. In some cases only one half is used, and this can be raised out of contact with the screw.

Classical (1) Pertaining to the art, literature, antiquities, etc., of ancient Greece and Rome. (2) Conforming to the styles of the foregoing. (3) Applied to a production, either painting or music, characterised by beauty of form, taste, and restraint.

Classicism. Tendency towards the classical style.

Classification of Elements. *See* PERIODIC SYSTEM.

Clastic Rocks (*Geol.*) A general term for rocks which have been built up from fragments. Thus clay, sand, sandstone, quartzite, gravel, conglomerate, arkose, are all clastic rocks. In cases where the chief fragments are directly of volcanic origin, as in the case of tuff and agglomerate, the resulting rocks are distinguished as PYROCLASTIC.

Claude Glass. Named after Claude Lorraine. A dark or coloured mirror used for reflecting landscapes. They are useful for artists in selecting and composing pictures.

Claus Kiln. *See* CHANCE'S PROCESS.

Claw Coupling *or* **Clutch** (*Eng., etc.*) A pair of flanges on the opposing ends of two shafts, with projections which engage each other when the two flanges are brought together, thus connecting the shafts so that they turn together. This form of clutch enables the shafts to be coupled or uncoupled instantaneously.

Claw Wrench (*Eng.*) A spanner or wrench with one loose hinged jaw, which grips tighter the more the pressure on it increases. A PIPE WRENCH is a form of claw wrench.

Clay (*Geol., etc.*) A clastic or derivative rock consisting essentially of a hydrous silicate of alumina, which is nearly always mixed in variable proportions with sand, lime, iron, or other minerals, or even with organic substances. Dry clay gives forth an argillaceous odour when breathed upon; and when it is moistened with water it is rendered plastic, and can be moulded without subsequently losing its shape. In other respects it varies so much that no general description can be applied to it.

Clay Band. *See* CLAY IRONSTONE.

Clay Cracked (*Pot.*) Ware is described as clay cracked if, when removed from the bisque oven, a crack is found which is traceable to the clay stage of its production.

Clay Ironstone. Nodules or concretionary masses, often of a rudely spherical form, which are composed essentially of a carbonate of iron mixed with more or less argillaceous matter. They usually occur in shales or in clays, and very commonly in close association with carbonaceous matter. Cracks are generally present in the interior of the nodules, and are often lined with calcite. These are then spoken of as SEPTARIA. Clay ironstone is, or was, largely used for the manufacture of iron. Some clay ironstones, also, are used for making hydraulic cement.

Clay Press (*Pot.*) A press used to squeeze the superfluous water from SLIP (*q.v.*), to convert it into clay.

Clay Slate (*Geol.*) An antiquated term which was loosely employed for any metamorphosed argillaceous rock with a tendency to split into thin plates. Under this head were included slates of argillaceous composition, phyllites, graphitic schists, and many other rocks of the same general character which it is now found convenient to distinguish by special names.

Clay Wash (Clay Water) (*Moulding*). Clay greatly diluted with water. In moulding, various objects are coated with a film of moist clay by washing with clay water in cases in which the foundry sand is required to adhere to them.

Cleading (*Eng.*) LAGGING (*q.v.*)

Clean Casting (*Eng.*) One free from faults on the surface or skin.

Clean Cut (*Eng., etc.*) A cut which is smooth and regular, as opposed to one which is ragged or which shows chattering (*q.v.*)

Cleaner (*Eng., etc.*) Applied to various tools; in moulding, a flat-bladed tool used for smoothing the surface of a mould. *See* SLEEKER.

Clean Fire (*Eng., etc.*) One which is burning brightly and is free from cinders, clinkers, and ashes.

Cleaning Eye (*Plumb.*) A brass cap screwed into the bottom of a lead trap. Refuse can be removed from the trap by removing the cap.

Clean Lift (*Moulding*). The withdrawal of a pattern from a mould without injury to the latter.

Clean Timber (*Carp.*) Timber that is free from knots and blemishes.

Clean Water (*Eng.*) Water required for use in boilers is said to be "clean" when it is free from visible impurities; it may, however, contain lime, etc., in solution, and therefore produce a deposit when used in boilers.

Clearance (*Eng.*) (1) The amount of space left between two parts which have to fit or engage together. (2) The space between a piston and the end of the cylinder in an engine when the piston is at the end of its stroke.

Clearcole. *See* CLAIRECOLLE.

Clearing Hole (*Eng.*) One bored out to its full nominal size; distinguished from a tapping hole (*q.v.*), which is bored to a smaller diameter in order that an internal thread may be cut in it.

Clearing Solution (*Photo.*) A solution of alum slightly acidified, in which negatives may be soaked to remove yellow stains produced during development by an alkaline developer.

Clear Oil (*Eng.*) Oil purified till transparent or of a light colour.

Clear Span (*Build.*) The horizontal distance between the abutments of a beam or arch.

Clear Story. *See* CLERESTORY.

Cleat. A wood or metal contrivance on which the free end of a rope, blindcord, etc., is coiled in order to make it fast.

—— (*Carp.*) A piece of wood nailed on the surface of one timber, and acting as a "stop" to assist in supporting another timber which rests upon the first; *e.g.* cleats are nailed on to rafters to support the purlins.

—— (*Mining.*) A cleavage in coal, not parallel to the bedding plane. *See also* COAL.

Cleavage (*Geol.*) A term now restricted to the parallel and usually closely set planes of division with one uniform direction, which have been induced in certain rocks partly under the influence of intense lateral compression. A cleaved rock splits with more or less facility in the direction of the cleavage quite independently of any structural planes originally present in the rock. Most slates were clays and of sedimentary origin; but some excellent slates in the Lake District were originally bedded tuffs, and therefore of volcanic origin. *See* FLAGSTONE, PHYLLITE, SCHIST, etc.

—— (*Min.*) A term used for the planes of more ready division of a mineral, pointing to a weaker cohesion along these planes. Cleavage planes are usually parallel to some crystal plane.

Clef (*Music*). A character representing a fixed sound and giving the name of that sound to the line on which it stands. There are three clefs: C, 𝄡 representing the middle C of the grand stave of eleven lines; G, 𝄞, a fifth above it; F, 𝄢 a fifth below it. *See* STAVE. These are often spoken of as the TENOR, TREBLE, and BASS CLEFS respectively.

Clerestory (*Architect.*) The uppermost division of the nave wall of a church immediately above the triforium or blind story (the space between the vaulting and roof over the aisle, frequently used as a gallery). The clerestory is pierced with windows overlooking the roof of the aisle, and was evidently constructed with the idea of increasing the light in the nave, the aisle windows being usually insufficient.

Cleveland Iron Ore. An important ore of iron occurring in the Jurassic rocks of Cleveland, Yorkshire, and other parts of the kingdom. It consists mostly of LIMONITE, with a variable percentage of iron in the form of MAGNETITE. It is nearly always due to a partial or entire replacement of a calcareous oolite by ferruginous matter imported into the rocks from some source at a higher level.

Cliché (*Photo.*) A term sometimes applied to the "negative" in photography.

—— (*Typog.*) An electro or stereotype plate; especially a metal stereotype of a wood engraving. to print from.

Click (*Eng.*) A small pawl (*q.v.*) or catch of a ratchet wheel.

Clicker (*Typog.*) The compositor who receives copy and distributes it to the other compositors or companionship of whom he has charge.

Clinker (*Eng., etc.*) (1) The residue from a furnace or fire from which practically all the available carbon has been burnt out. It is often partly fused, and resembles slag. (2) A small hard brick used for paving

Clinkering (*Eng.*) The extraction of clinker from a fire.

Clinodiagonal (*Min.*) An axis of the Monosymmetric System inclined to the vertical axis at a definite angle in each mineral of the system, and at right angles to the Orthodiagonal (*q.v.*) *See* SYSTEMS OF CRYSTALLOGRAPHY.

Clinodome (*Min.*) A face parallel to the CLINODIAGONAL (*q.v.*)

Clinograph (*Drawing Office*). An instrument used by draughtsmen when drawing two or more similar angles in succession. It resembles the carpenter's bevel (*q.v.*) in principle, but has the stock and blade of the same thickness, like a footrule, in order that the instrument may lie flat upon the drawing paper. The clinograph is invaluable in graphic calculation in statics, when reciprocal figures have to be drawn. *See* GRAPHIC STATICS.

—— *or* **Clinostat** (*Surveying*). An instrument used for detecting deflections from the vertical in a bore hole; it measures and automatically registers the amount of the deflection.

Clinometer (*Surveying*). Any instrument for measuring vertical angles. There are many different forms adapted to various circumstances.

Clip (*Build.*) A slip of lead or copper to prevent slates or tiles from slipping on a roof.

Clip Drum: Clip Pulley (*Eng.*) A pulley with some form of movable clips in the rim. These grip the rope passing between them, thus preventing it from slipping over the pulley. Used for hauling in mines, etc.

Clipeus (*Armour*). A round shield carried by Greek and Roman soldiers, made of wickerwork covered with hide, or of beaten bronze. The SCUTUM was oval or oblong.

Cloaca (*Zoology*). A chamber formed by the last portion of the large intestine in the birds, reptiles, amphibia, and many fishes. The cloaca receives the openings of the genital and urinary ducts.

Cloanthite (*Min.*) An arsenide of nickel, $NiAs_2$. Nickel = 28·4, arsenic = 70·34 per cent., with traces

of impurities. Crystallises in tin-white cubes, but is often associated with the pinkish tinge of Cobalt Bloom, as cobalt usually replaces some of the nickel: in fact, a gradation occurs from Cloanthite to SMALTITE (*q.v.*) Found in Cornwall, Saxony, Bohemia, Sweden, Dauphiny, etc.

Clockmaking. *See* WATCH AND CLOCKMAKING.

Clock Stars (*Astron.*) Stars whose times of transit are known; they are observed in order to find the RATE and ERROR (*q.v.*) of an astronomical clock or a chronometer.

Clogging (*Eng.*) The hardening or thickening of lubricating oil. It tends to check, or even stops, the motion of moving parts of machinery.

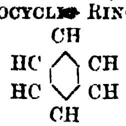
Cloissoné (*Dec.*) Mosaic work in glass or enamels. Japanese cloissoné is a mosaic of enamel on a metal ground. Cloissoné glass consists of two sheets of plain glass, with a design between formed of bent copper strips, the whole of the remaining space being filled in with glass globules of various beautiful colours.

Cloister (*Architect.*) The covered way connecting a cathedral with the refectory, chapter house, etc. It usually forms three sides of the quadrangle or garth, the fourth side being formed by the wall of the south nave of the cathedral, as at Wells.

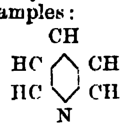
Close (*Architect.*) An enclosure around a large building, such as a cathedral. It is usually surrounded by houses which serve as official residences for the cathedral clergy. In many of the English cathedrals the close adds greatly to the general effect: Salisbury is perhaps the best example.

—— (*Music*). Used in the sense of cadence. "Full close" = perfect cadence; "Half close" = imperfect cadence.

Closed Chain Compounds (*Chem.*) When a number of atoms are joined together in a ring as distinct from a chain, the system is called a closed chain, and its derivatives closed chain compounds. When all the atoms in the ring are alike, the ring is called an ISOCYCLIC, when they are not all alike, a HETEROCYCLIC RING. Examples:



Benzene.



Pyridine.

Closed Coil Armature (*Elect. Eng.*) An armature in which there is a complete path for the current without passing through the External Circuit: the end of one coil or set of turns is joined to the beginning of the next.

Closed Shed (*Cotton Weaving*). The opposite to OPEN SHED. Between each pick inserted in the shed, the tappet, dobby, or Jacquard will allow the heald or harness thread to move to its bottom or central position, and thus close its shed previous to forming another for the next pick of weft. *See* OPEN SHEDDING, SHEDDING.

Closed Stokehold (*Eng.*) *See* FORCED DRAUGHT.

Close Grain. Material the fibres of which are very close together: a purely relative term, incapable of exact definition.

Close Mouth: Closed Mouth (*Eng.*) Applied to punching machines whose jaws are closed at the sides and open at the back and front, thus permitting the passage of narrow bars or rails, but not of sheets of metal.

Closer (*Build.*) A quarter of a brick used for bonding.

Close String (*Carp. and Join.*) In staircase work an outside STRING (*q.v.*) that is not notched out to support the steps.

Closet (*Her.*) A diminutive of the Bar, and one half its width.

Close Test. *See* FLASH POINT.

Close Topped Furnace (*Met.*) A blast furnace (*q.v.*) whose top is closed by a cone. *See also* FURNACES.

Closets, Earth (*Hygiene*). Consist of a wooden box with a receptacle for the excreta below, and a hopper containing dry earth above. When the plug is pulled, the dry earth is thrown on to the sewage. Dry earth is a very powerful deodoriser; the best kinds are dried clay, marl, and loamy soil.

Closing Up (*Eng.*) (1) The formation of the second head of a rivet after it is placed in position. (2) The completion of a foundry mould by placing the uppermost part in its final position.

Cloth (*Woollen Manufac.*) A woven, knitted, or felted structure composed of fibres.

Cloth Binding (*Bind.*) Binding in which the "boards" are covered with prepared calico, plain or embossed with a design.

Clothed (*Her.*) A shield almost covered by a lozenge, but having the corners uncovered.

Clothing: Cleading (*Eng.*) The covering of steam pipes and vessels with non-conducting materials. *See also* LAGGING.

Cloth Red. *See* DYES AND DYEING.

Cloud Negatives (*Photo.*) Separate negatives of clouds, used for printing-in skies in ordinary landscapes in which the whole sky usually appears uniformly bright. They are often taken on flexible films for greater convenience in handling.

Clouds (*Meteorol.*) The visible form assumed by moisture in the atmosphere, identical with MIST. Clouds consist of a great number of minute drops of water. In certain cases these drops may be frozen, so that a cloud may consist of particles of ice. *Forms of Clouds:* Clouds have been classified according to the general form which they present to an observer viewing them from the earth's surface. CIRRUS CLOUDS are feathery streaky clouds formed high up in the air; STRATUS is a form consisting of a sheet of cloud of approximately uniform thickness, occurring low down; CUMULUS is a billowy rounded form, often seen in summer; NIMBUS is the rain cloud, with well defined edges, generally very dark and heavy looking. Meteorologists also use the expressions CIRRO-CUMULUS, CUMULO-STRATUS, etc., to denote combinations of the simple forms. *Formation of Clouds:* It was formerly thought that if air containing water vapour were cooled down, either by sudden expansion or by contact with colder air, till it reached the temperature at which it became saturated, that clouds were necessarily produced. It has been shown, however, that this is not necessarily the case. Aitken and others showed that the presence of particles of dust is of very great importance; in the complete absence of dust the first drops would have a radius comparable with the dimensions of a molecule, and in this case the surface tension of the drops would cause the rate of evaporation to be so great that the drop could not continue to exist. If, however, fine dust particles are present,

the drops are first formed by condensation on the surface of the particles, and the drops thus commence their existence with dimensions so much greater than those of the molecule that the gain in size from condensation more than balances the loss from evaporation. This effect is easily shown by experiment: if damp air from which dust has been entirely removed be suddenly cooled by expansion, no visible condensation will occur; but the admixture of a very small amount of ordinary air, which always contains a great number of dust particles (upwards of 100,000 per cubic inch), will cause a visible cloud to appear when the damp air is allowed to expand suddenly. The researches of Aitken and others led to the belief that dust was always essential to the formation of clouds; but it has since been shown that the presence of gaseous IONS (*q.v.*) in the air is capable of producing the same result. These ions are charged particles, some having charges of negative, others of positive electricity. They may be produced by a variety of agencies—*e.g.* Röntgen, Kathode, and Lenard rays; the radiation from uranium, radium, polonium; by ultra-violet light. Under normal conditions, free ions are always present to some extent in the air, and the number will be increased when the air is exposed to the action of any of the above ionising agencies, and the necessary conditions for condensation and the formation of clouds will be set up.

Cloudy Web (*Cotton Spinning*). Uneven thickness in the sheet or web as it comes from the doffer, caused by defective carding.

Clout Nail. A nail with a large flat head.

Clove. The well known clove is the dried flower bud of an East Indian plant of the *Myrtle* family—*Eugenia caryophyllata*; order, *Myrtaceæ*.

Club (*Her.*) A primitive weapon sometimes used as a charge or placed in the hand of a savage.

Clustered Lotus Bud Capital (*Architect.*) This is one of the capitals used in Egyptian architecture. The column with which it is used represents a bundle of lotus flower stalks banded together at intervals, and the capital is a conventional treatment of a lotus bud, its main lines following those of the stalks in the column. *See* LOTUS FLOWER *and* LOTUS CAPITAL.

Clustered Pillar (*Architect.*) A pillar consisting of several shafts, a common form in Gothic architecture. It usually consisted of a large central pillar, either circular or square, surrounded by smaller shafts. *See* PILLAR *and* MONOSTYLE.

Clutch (*Eng.*) Any device for connecting two pieces of shafting in line, so that they turn together. *See* CLAW CLUTCH, FRICTION CLUTCH, *etc.*

Co. Chemical symbol for cobalt (*q.v.*)

Coach Screw (*Eng., Carp., etc.*) A large screw for heavy timber work, with a square head, which is turned by a spanner instead of by a screwdriver.

Coal. A stratified deposit of compressed and mineralised vegetable matter occurring in the fossil state. Changes have occurred in its chemical composition which have reduced the oxygen originally present to 15 per cent. or less, the relative amount of carbon being consequently increased to 70 per cent. or more. The structure present in the vegetable matter from which coal has been formed is but rarely traceable. Amongst unaltered vegetable products, the nearest approach to coal in respect of chemical composition is to be found in caoutchouc, gums, and resins. Coal presents a wide range in chemical composition, owing to the variable percentage of carbon present and the amount of mineral impurities with which it may happen to be mixed. The percentage of carbon may rise to 90 or more in the best fuel, and may fall to 60 or even less in the varieties which graduate into BROWN COAL and LIGNITE. Furthermore, owing to the fact that coal seams are not homogeneous from top to bottom, but consist of aggregates of thin laminæ, each of which may vary greatly in composition from those above it or below, it follows that different parts of a coal seam at the same spot may have quite different values as fuel. The variation in this latter respect may be still more strongly marked when a comparison is made, of the composition of various examples of the same seam taken from different parts of the coalfield in which the seam occurs. The variation referred to is usually connected with the aggregate percentage of mineral matter, usually clay, that originally entered into the composition of each of the several laminæ of which the coal seam is built up. It may be further affected by the presence of mineral matter, such as pyrites, developed within the seam after the original constituents of the coal were laid down. Three kinds of coal may be observed in each example of most coal seams from strata of Carboniferous age. One of these is quite amorphous, bright, and with a lustrous fracture like the surface of polished jet. This is often referred to as CHERRY COAL. Another kind is also amorphous, gives a conchoidal fracture, and the lustre is dull, like that of clay. This is CANNEL COAL. The third constituent, which is usually present in much smaller proportion, has the general appearance of charcoal, and distinctly shows traces of vegetable structure. It is indeed simply vegetable tissue more or less mineralised. This is a mineral charcoal, often called MOTHER OF COAL. Carboniferous Cherry Coal is largely composed of the resinous spores of lycopodiaceous plants; Cannel Coal represents vegetable tissues which have passed into a pulpy condition through prolonged maceration, while Mineral Charcoal is the representative of such of the vegetable tissues as have been able to resist the change arising from maceration. Another variety of coal, which is of great value as fuel, is known as ANTHRACITE. It contains a high percentage of carbon; is amorphous, heavy, hard; does not soil the fingers; and it gives off little or no smoke when it is being burned. Its peculiarities are due to changes which it has undergone within the Earth's crust; one of the factors concerned in the change appearing to be the presence of water at a high temperature. In the neighbourhood of rocks of an intrusive nature, coal seams have undergone more or less deterioration, and are, in many cases, thus rendered quite valueless. A further cause affecting the commercial value of coal seams is the fact that they tend to graduate horizontally into stratified rocks of other types, useless as fuel. Thus the argillaceous laminæ present in a seam may be small in proportion to the good coal at one place, and yet may show a gradual increase when followed in the direction of a place at no great distance; the change may even proceed so far as to end in a total replacement of the coal seam by carbonaceous shale, of no commercial use. The coal may gradually pass, in like manner, into clay ironstone or into oil shale. The origin of coal seams has been a fertile source of diversity of opinion for a long time. The orthodox view is that it has been

formed on the land as ordinary vegetable growth, when the part of the surface of the Earth where the growth took place has been undergoing intermittent subsidence. Another view, held at present by only a small number of persons, is that, in most cases, coal represents submarine deposits formed off the mouths of the rivers that brought down the vegetable spoils of the land. The salts dissolved in the sea water, and especially the sulphate of lime, are supposed to have been concerned in bringing about some of the chemical changes which have altered the composition of the vegetable substances. The varying powers of resistance to maceration presented by the different vegetable constituents, and the sorting action of water in motion, are sufficient to account for the formation of the layers of different composition. The most essential feature required for the growth of the plants that give rise to extensive beds of coal seems to be a moderately warm and humid climate, which has but a small diurnal and annual range of temperature. Coal occurs in rocks of almost all ages, from those of Carboniferous times—which afford the chief supply of Western Europe—down to others of comparatively recent age. Coal of Lower New Red or "Permian" age occurs in Westmoreland, but it is of no commercial value. Coals of Jurassic age occur in the North of England, and have long been worked for fuel in North-Eastern Scotland. Coal of Neocomian age is known in the South of England. In other parts of the world coal seams in every respect like those occurring in British Carboniferous rocks have been worked in strata belonging to all geological horizons, ranging from Palæozoic up to those of Late Tertiary age. The coals worked in the Midland counties, in Wales, and the parts of England adjoining, pertain to the Upper Carboniferous rocks; but in the North of England, and in Southern Scotland, commercially important coal seams also occur in rocks of Lower Carboniferous age. The coal seams worked in Ireland are usually regarded as being exclusively of Upper Carboniferous age. Amongst the changes which coal has undergone below ground is the development of two (or more) sets of cross fractures perpendicular to the planes of bedding. These divide the coal seams into nearly rectangular portions at close horizontal intervals. These natural divisional planes or joints are known as the CLEAT. They are important factors in the "winning" or extraction of the coal. Several other factors which affect the profitable working of coal remain to be noticed. One of the most important is the nature of the "roof" or bed overlying the coal seam. It is important, in this respect, that the roof should be rigid enough to stand, without much artificial support, over the parts whence the coal has been mined. Another factor is the amount of inclination from the horizontal position which the strata, including the coal seams, have undergone. The presence or the absence of the planes of dislocation (FAULTS) is always an important consideration. The facilities which the position of the mine afford for both ventilation and drainage are, again, of much importance. Lastly, the liability of coal seams to be CUT OUT (*i.e.* to disappear, or be suddenly terminated) has to be taken into consideration. One cause of this nature is due to old channels of erosion, along which the coal has been locally removed while the rocks were in process of formation. These are called WASH-OUTS. Another is due to the presence of sandbanks or other rising ground, against which the deposition of the carbonaceous matter has locally terminated. These banks are known as HORSES. The remaining factor is connected with the formation of eruptive masses, by which the coal seams and their accompanying strata have been invaded after their formation. These intrusive rocks not only cause a deterioration of the coal seams in their neighbourhood, but they also "cut out" (*i.e.* remove) the strata, including the part of the coal seams invaded, wherever they occur. The intrusive rock generally passes into the condition of WHITE TRAP, or WHITE HORSE, in the neighbourhood of the carbonaceous matter, chiefly as a consequence of the reducing action of this latter upon the iron compounds present in the intrusive mass.—J. J. G.

Coal Dust (*Moulding*). Mixed with foundry sand for moulding, and also used as blacking (*q.v.*), or facing for the mould itself.

Coal Gas. *See* GAS MANUFACTURE.

Coal Tar Distillation. *See* GAS MANUFACTURE: COAL TAR DISTILLATION.

Coal Tar Dyes. *See* DYES AND DYEING.

Coarse Hard (*Eng., etc.*) Applied to emery and emery wheels used for rough work.

Coarse Metal (*Met.*) *See* COPPER.

Coarse Stuff (*Plast.*) Lime and sand mixed with hair for the first coat of plastering.

Coat Armour (*Her.*) (1) A coat or garment, bearing armorial insignia, which was worn over armour. (2) Armorial insignia borne by a gentleman.

Coating (*Paint.*) A preparation of plaster placed on the wall for fresco painting.

Coating Machine (*Paper Manufac.*) A machine used for making "art" paper by coating ordinary paper with mineral matter, such as China clay, etc.

Coat of Arms (*Her.*) As now understood, a complete and distinctive heraldic composition: derived originally from the coat armour (*q.v.*)

Coat of Mail. A piece of armour for covering the upper part of the body, consisting of interlaced rings or overlapping plates of iron or steel, attached to a strong linen or leather jacket. The Greeks and Romans wore coats of mail, termed respectively "thorax," and "lorica." *See* ARMOUR (MAIL).

Cobalt, Co. Atomic weight, 59. A white metal with bluish shade (sp. gr. 8·7), harder than iron: magnetic. melts at 1500°: unchanged in air: slowly dissolved by hydrochloric and sulphuric acids, quickly by nitric acid. It is used in electroplating; articles so plated are described as "superior nickel plate." Obtained by strongly heating the oxalate out of contact with air; or reducing the oxide in hydrogen or by heating it with aluminium powder. *See* GOLDSCHMIDT'S PROCESS. Occurs with nickel, and also combined with arsenic and sulphur. This element has not been found native, but it exists in combination in nature in the minerals SMALTINE, COBALTINE, ERYTHRINE, ASBOLANE, and other rarer ones.

—— (*Dec.*) A useful blue pigment of a greenish hue. It is quite permanent, and works better in water than it does in oil.

Cobalt Bloom (*Min.*) A synonym for ERYTHRINE (*q.v.*)

Cobalt Compounds. COBALT OXIDE, Co_3O_4. An oxide of this formula is prepared on a large scale for making SMALT (*see* below), and for colouring glass and porcelain blue, and for preparing cobalt

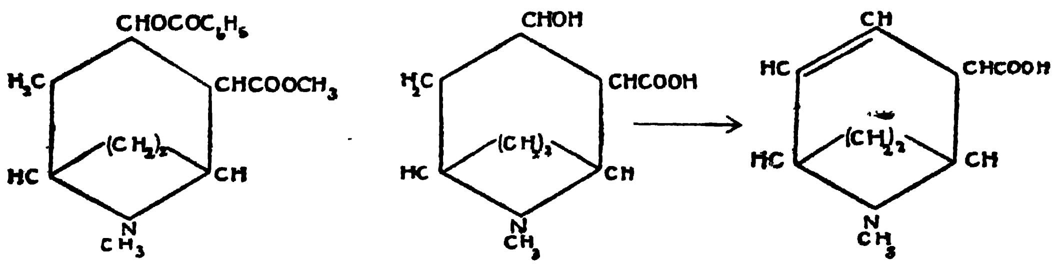
salts. The cobalt ore is roasted, dissolved in acid, and treated with sulphuretted hydrogen to separate arsenic, bismuth, etc.; the solution is then precipitated with sodium carbonate, and the precipitate, treated with oxalic acid, gives a mixture of the insoluble oxalates of nickel and cobalt. On adding ammonia and leaving exposed to air, the cobalt is dissolved and the solution evaporated, and the residue heated in air gives the oxide. SMALT is a double silicate of cobalt and potassium, and is made by heating cobalt oxide with potassium carbonate and finely divided quartz; it is extensively used as a pigment. COBALT CHLORIDE, $CoCl_2$, is blue when anhydrous, and pink when in solution, and is obtained by action of chlorine on the metal or solution of the oxide in hydrochloric acid. COBALT NITRATE, $Co(NO_3)_2$, a red deliquescent crystalline solid obtained by dissolving the oxide in nitric acid. It is used in blowpipe analysis. Solutions of cobalt salts are used as SYMPATHETIC INKS—the pale pink writing is almost invisible, but when warmed before a fire, a trace of moisture is driven off, and the colour becomes blue and is visible.

Cobalt Green (*Dec.*) A pigment composed of zinc and cobalt oxides. It is permanent, but inferior to chrome green (*q.v.*)

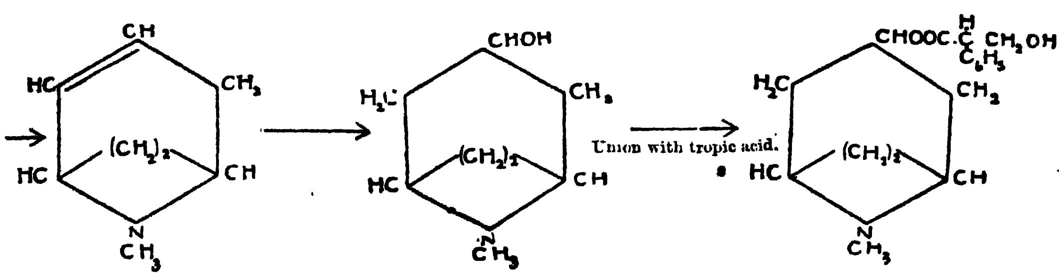
Cobaltine (*Min.*) A sulphide and arsenide of cobalt, CoAsS. It occurs in tin-white crystals of the cubic system. The crystals usually have a faint pink tinge. Also found massive. It is used in the manufacture of smalt. Found in Cornwall, many localities in Sweden and Norway, in Westphalia, etc.

Coca. *Erythroxylon Coca* (order, *Erythroxylaceæ*). The dried leaves are used for the preparation of the alkaloid COCAINE (*q.v.*)

Cocaine. A white crystalline solid; melts at 98°; readily soluble in alcohol, chloroform, and ether; with difficulty in water; lævorotatory. It is a valuable local anæsthetic; very poisonous. Occurs in leaves of *Erythroxylon coca* (South America), and is obtained from the leaves by treatment with caustic soda and petroleum of high boiling point. From solution in petroleum the base is extracted by hydrochloric acid, giving a crude hydrochloride, which is purified. It is also largely produced, synthetically, from ECGONINE, obtained from the mother liquor resulting in the preparation of cocaine. The ecgonine is converted into the methylester by methyl alcohol and hydrochloric acid gas, and this is then treated with benzoyl chloride, yielding cocaine hydrochloride. Cocaine is recognised by the pleasant smell of methyl benzoate, which it gives on warming for some time with alcoholic potash, and by its numbing action when a drop of its solution is placed on the tongue. The following facts are important in relation to the constitution of cocaine: Boiled with water, it gives methyl alcohol, (CH_3OH), and benzoyl ecgonine; boiled with strong acids, it gives methyl alcohol, benzoic acid and ecgonine; cocaine can be reproduced from these (*see* above). It is a tertiary base (*q.v.*) Ecgonine contains a methyl group attached to nitrogen, as it yields methylamine, (CH_3NH_2), when heated with baryta; it is an alcohol, as it loses one molecule of water and forms ANHYDROECGONINE on treating with acetic anhydride and hydrochloric acid gas. Anhydroecgonine is an acid, and it is unsaturated because it adds two atoms of bromine; also, on heating with hydrochloric acid, it loses carbon dioxide and forms tropidine. This last fact establishes the relation to atropine. These facts are all explicable by the following formulæ:



COCAINE. ECGONINE. ANHYDROECGONINE.



TROPIDINE. TROPINE. ATROPINE.

Cocculus Indicus. The one seeded dry fruits of a Malayan climber, *Anamirta cocculus* (order, *Menispermaceæ*). Used in medicine and sometimes as an adulterating agent in porter, etc. The seeds contain an alkaloid, Picrotoxin.

Cochineal. The scale insects allied to the common plant lice (*Aphis*) include the cochineal insect, *Coccus cacti* (order, *Rhynchota*), which infests a Mexican cactus (*see* OPUNTIA). The wingless female insect, dried, is the source of the colouring matter.

The dried bodies are treated with boiling water and a small quantity of alum or cream of tartar, under which treatment they yield a rich crimson pigment used in the manufacture of CARMINE and other LAKES (*q.v.*) *See* DYES AND DYEING.

Cock (*Eng.*) A general term used in engineering, etc., for a tap for the passage of water, or other fluid, or occasionally for some other form of valve opened by hand. The word "tap" (*q.v.*) is applied by engineers to a special tool for cutting internal screw-threads.

Cockatrice. A mythical composite creature partly serpent and partly cock, identical with the basilisk (*q.v.*)

Cocked Bead (*Carp. and Join.*) A half round bead standing above the general surface of the work.

Cockling (*Textiles*). Irregular weaving of warp threads caused by uneven tensioning, thus giving a raw appearance to the cloth.

Cock's Eye (*Plumb.*) *See* BIRD'S EYE.

Cock Up (*Typog.*) Applied to a large type used as the initial letter of the first word of a book or chapter, the foot ranging with that of the other type in the line.

Cocoa. This article of food is prepared by roasting and grinding the seeds of *Theobroma cacao* (order, *Sterculiaceæ*). The fruits contain from fifty to a hundred seeds. Cocoa is nutritious, containing a large amount of fat and starch. Its active principle is THEOBROMINE (*q.v.*) It is often adulterated by the addition of sugar and starch, also by mineral matter, which is added for the purpose of colouring.

Cocoanut. *Cocos nucifera* (order, *Palmæ*). This tropical palm is the source of many important economic products. The fibrous covering of the nuts is used for matting, brushes, and ropes.

Cocoon. *See* SILK.

Cod. The codfish, *Gadus morrhua* (family, *Gadidæ*), and its near allies form an important economic group of food fishes. The oil and skins are also valuable. *See* COD LIVER OIL.

Coda (*Music*). A tail or ending: that portion of a composition or movement which serves as an ending.

Codeine (*Chem.*) $C_{17}H_{18} . CH_3 . NO_3$. An alkaloid. It forms colourless crystals; soluble in water (1 in 80); readily soluble in alcohol and chloroform. It is methyl morphine (*see* MORPHINE), and its physiological action is similar to that of morphine, but less in degree. Occurs with morphine in opium (·3 to 2 per cent.) It can be made from morphine (*q.v.*)

Codetta (*Music*). A short coda.

Cod Liver Oil. A valuable oil obtained from the liver of the common cod. Of the three varieties, pale, pale brown, and brown, the first only is used for medicinal purposes, and is obtained by steaming fresh livers taken from the fish as soon as they are brought ashore. The other two varieties are obtained from livers partly decayed, and are largely used in the manufacture of certain leathers. Sp. gr., 0·922 to 0·930 at 60° F.

Coefficient. A numerical quantity (commonly obtained by experiment) which enters into a formula as a multiplier.

Coefficient of Elasticity. *See* ELASTICITY.

Coefficient of Expansion. (*Heat.*) *See* EXPANSION.

Coefficient of Friction. *See* FRICTION.

Coefficient of Leakage (*Elect. Eng.*) The ratio of the total number of magnetic lines produced by the field magnets of a dynamo, etc., to the total number which passes through the coils of the armature.

Coefficient of Magnetic Induction (*Elect.*) *See* PERMEABILITY.

Coefficient of Magnetisation (*Elect.*) *See* SUSCEPTIBILITY.

Coefficient of Mutual Induction (*Elect.*) If there be two neighbouring circuits, and unit current in one of them cause a certain number of lines of force to pass through the second circuit, then that number of lines is termed the COEFFICIENT OF MUTUAL INDUCTION of the two circuits.

Coefficient of Rigidity. *See* RIGIDITY.

Coefficient of Self Induction (*Elect.*) The total number of lines of force that are caused to pass through a circuit by a unit current flowing in it.

Coefficient of Transformation (*Elect. Eng.*) The ratio of the E.M.F. in the secondary coil of a transformer to the E.M.F. in the primary coil. *See also* TRANSFORMER.

Cœlom (*Zoology*). A term applied to the body cavity of an animal. The cœlom is bathed in a watery fluid (the serous fluid).

Coercive Force (*Elect. Eng.*) The amount of magnetising force that must be applied to an electromagnet in the reverse direction to the original force which was used to magnetise it, in order to reduce the remaining magnetism to zero. The better the quality of the iron the less the remaining magnetism; hence the less the coercive force necessary. *See also* HYSTERESIS.

Cœrulein, Cerulein. *See* DYES AND DYEING.

Cœruleum (*Paint.*) An artist's pigment of a greenish blue hue. It is made from oxides of tin and cobalt; is perfectly fast to light (*i.e.* is not affected by light). It may be imitated on the palette by mixing ultramarine, viridian (*q.v.*), and white.

Cœur (*Her.*) Sometimes used to denote the centre of a shield; otherwise called the centre or fesse point.

Coffee. The so-called COFFEE BEANS are the horny seeds of a cherry-like fruit, *Coffea arabica* (order, *Rubiaceæ*). Coffee has a stimulating effect on the nervous system, its active principle being CAFFEINE (*q.v.*) Coffee is frequently adulterated, more especially when sold roasted and ground. The adulteration can be detected by microscopic examination. The addition of chicory is perfectly legitimate, providing that disclosure is made of the mixture at the time of purchase.

Coffer (*Architect.*) A sunk panel in a dome, vault, or soffit (*q.v.*)

Coffer Dam (*Civil Eng.*) A water-tight enclosure constructed in a river, lake, etc., reaching from the bottom of the water to the surface. It is emptied of water by pumps to enable engineering or building operations to be carried on in the bed of the river.

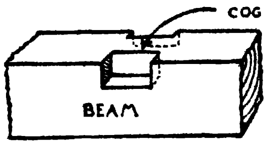
Coffered Ceiling (*Plast.*) A ceiling moulded in the form of panelling.

Coffering (*Mining*). Lining a shaft with masonry, the stones being shaped in plan like the voussoirs of an arch, and built up into successive circular courses.

Cog (*Build.*) *See* COGGED JOINT.

—— (*Eng.*) The tooth of a gear wheel; more especially a wooden tooth, formerly much used in MORTICE WHEELS (*q.v.*)

Cogged Joint (*Carp. and Join.*) A joint having a projection, termed a COG, in the centre.



COGGED JOINT.

Cogging (*Eng.*) Fitting the teeth of a mortice wheel.

—— (*Met.*) The conversion of steel ingots into blooms in a cogging mill or rolls.

Cognisance (*Her.*) A badge or device adopted as a distinctive mark, not placed upon a shield, or used as a crest; *e.g.* the ostrich feathers of the Prince of Wales.

Cognoscente (*Art*). A connoisseur.

Coherer (*Elect.*) A form of detector for electric waves. *See* WIRELESS TELEGRAPHY.

Cohesion (*Phys.*) The property of holding together possessed by the particles of a solid or (to a less extent) by a liquid.

Coif (*Cost.*) (1) In early use, a close fitting cap or hood tied under the chin and worn out of doors by both sexes. The head covering of women in foreign countries. (2) A cap worn by serjeants-at-law, afterwards represented by a white border or a small patch of black silk on the top of the wig.

Coil (*Eng., etc.*) (1) A number of turns of wire, rope, etc. (2) Turns of piping used for the purpose of radiating heat. (3) In electricity, a number of turns of wire (usually insulated) wound either on a solid core or on a hollow reel; especially an INDUCTION COIL (*q.v.*) *See also* SOLENOID.

—— (*Motor Car*). An INDUCTION COIL (*q.v.*) which gives a hot spark for igniting the explosive charge in the cylinder. The coil is usually worked by an accumulator of two cells, giving about 4 volts.

Coiler (*Cotton Spinning*). A mechanism attached to the carding and drawing machines for coiling the strands or SLIVERS (*q.v.*) in a special tube-shaped can.

Coins. Flat pieces of metal of various thickness and value, generally bearing the image of the sovereign, or some symbolical figure or figures. Ancient coins, especially those of Greece, are of great importance as objects of art, and they also serve to illustrate the history of art. *See* BLANKS.

Cointise (*Cost.*) A fanciful dress. The pendant scarf on ladies' headdresses; sometimes worn by knights on their helmets in jousts as a "favour."

Coke. The product of the destructive distillation of coal (*cf.* CHARCOAL). GAS COKE is the result of heating coal in retorts in gasmaking. OVEN COKE, or HARD COKE, used for smelting and various metallurgical operations, is manufactured in special ovens or furnaces. The essential requirement in coke used for these latter purposes is freedom from sulphur, arsenic, and phosphorus, but up to the present time it has not been found possible to eliminate all sulphur. Coke is also used to a large extent as a medium for the bacterial treatment of sewage, for which purpose it seems to answer well.

Coke Bed (*Met., Foundry, etc.*) (1) A layer of coke placed at the bottom of a cupola. (2) A layer placed below large moulds, forming a porous mass which affords a means of escape for the gases produced during the pouring of the metal into the mould.

Coke Breeze. Crushed coke: used as fuel, as a filling for hollow floors in building, and for various other purposes.

Coke Mill (*Foundry*). A mill for grinding coke into powder for use as blacking (*q.v.*) in a foundry.

Coke Plate (*Met.*) Thin sheet made from ordinary puddled iron. It was originally so called to distinguish it from iron refined by means of charcoal.

Colas' Process (*Photo.*) A printing process in which the paper is coated with ferric salts, which are converted into ferrous salts under the action of light. The print is developed by gallic acid, which blackens the portions unacted on by the light. This process gives a negative from a negative, and a positive from a positive; hence, in copying a tracing, it gives black lines on a white ground.

Colcothar (*Chem.*) The commercial name for a red pulverulent ferric oxide, (Fe_2O_3). Also known as ROUGE.

Cold Air. *See* REFRIGERATORS.

Cold Bend (*Eng.*) Testing iron bar and plate by bending. The angle at which cracking begins is a test of the quality of the iron; hence this is often laid down in the specifications of contracts for ironwork.

Cold Blast (*Met.*) The old method of working blast furnaces, etc., by a blast of cold air; it was less economical, but produced a better quality of iron than the modern Hot Blast. It is now almost obsolete.

Cold Chisel (*Eng.*) A chisel of strong hard steel, made of one piece of metal, and tempered so as to be able to cut iron when struck with a chipping hammer, but not made so hard as to be liable to fracture under the blows. This requires the steel to be tempered to a colour varying from brownish yellow to light purple, *i.e.* from 500° to 530° F. *See* TEMPERING. Also used for cutting brick, stone, etc.

Cold Iron Saw (*Eng.*) A small thick circular saw with the cutting edge of the teeth parallel to the axis of the saw; run at a slow speed.

Cold, Production of (*Physics*). *See* REFRIGERATORS.

Cold Riveting (*Eng.*) Closing up rivets without previously heating them. This method of riveting is always used with copper rivets, but is not used with iron ones, except in the smaller sizes.

Cold Rolling (*Eng.*) The rolling of iron, cold, gives considerable tensile strength, but lowers the toughness; much greater smoothness of surface is obtained than when rolled hot.

Cold Set (*Eng.*) A short chisel fastened to a long rod at right angles to its length, used by smiths for cutting iron bars without heating.

Cold Short (*Eng., Met.*) Iron or steel which is brittle "in the cold" (*i.e.* below a dull red). This defect is chiefly due to the presence of phosphorus, arsenic, or silicon. *Cf.* RED SHORT.

Cold Test (*Eng.*) *See* COLD BEND.

Cold Water Test (*Eng.*) Hydraulic testing of a boiler with cold water, as distinguished from tests with hot water or steam. The water is forced into the boiler under pressure, and the seams, etc., are examined for leakage, yielding, etc.

Collar (*Eng.*) A ring on a shaft either turned up out of the solid metal or added as a separate piece, usually to prevent end play or longitudinal motion of the shaft.

—— (*Orders*). An ornament in the form of a chain worn round the neck, especially as the insignia of an order of knighthood. A collar is part of the investiture, and is worn by the knights of the following English Orders: Order of the Bath, St. Michael and St. George, and the Star of India.

Collared (*Her.*) Wearing a collar.

Collaring (*Met.*) The adhesion of a bar to the rollers during the operation of rolling.

Collar Roof (*Carp.*) A roof having a horizontal beam (collar) fixed to the rafters one-half or one-third of the way up, to prevent them spreading or sagging. *See also* ROOFS.

Collate (*Typog. and Bind.*) To examine or to place in order, by their signatures, the sheets of a book: a SIGNATURE being a letter or figure in the white line at the foot of the first page of each sheet or section of a book.

Colla Voce (*Music*). With the voice. Used in accompaniments.

Collecting Rings (*Elect. Eng.*) The insulated rings on the shaft of an alternate current machine by which the current is led away from, or into, the machine from the external circuit. They are used in most cases when a current has to be led into, or out of, any circuit (*e.g.* a ROTOR, *q.v.*) carried on a revolving shaft. Each end of the wire forming the circuit is attached to one ring; a brush or conductor of suitable form, supported by an insulated holder, presses on each of the rings as they revolve; the external circuit is connected to these conductors, and through them to the revolving part of the machine.

Collidines (*Chem.*) The TRIMETHYL PYRIDINES. *See* PYRIDINE.

Collodion. A solution of PYROXYLINE (*q.v.*) in alcohol and ether. It is used in making artificial silk, plates for photography, and for covering small wounds to exclude air, etc. Collodion-covered or "wet" plates are now superseded in ordinary cases by gelatine films, but are still used in certain special kinds of photographic work.

Colloid (*Phys.*) Substances of the nature of jelly (*e.g.* glue, gelatine, albumen). They are non-crystalline, can only diffuse very slowly through a membrane, and probably possess very large molecules.

Colloidal (*Phys*) Having the properties of a COLLOID (*q.v.*) Many bodies, *e.g.* silica, can exist both in a crystalline and in a colloidal or amorphous form.

Cologne Earth (*Paint.*) A deep brown pigment prepared from lignite or partially fossilised wood. It is transparent and durable.

Cologne Yellow (*Paint.*) A pigment produced by mixing chromate and sulphate of lead with sulphate of lime.

Colon (*Typog.*) A punctuation mark, thus :

Colonnade (*Architect.*) A range of columns either attached to a wall or at some distance from it. *See* PORTICO *and* PERISTYLIUM.

Colophon (*Typog.*) A device or emblem placed at the end of a book or manuscript. Formerly (*i.e.* in early printed books) it conveyed the information now given on the title page.

Colossus (*Sculp., etc.*) A statue or figure many times larger than life size. Amongst remarkable examples are the statue of Apollo at Rhodes, the Egyptian Sphinx, the figure of Osiris, and the modern statue of *Liberty*, from the design by Bartholdi, erected at the entrance to New York harbour.

Colour (*Botany*). Any part of a plant which is not green is said to be "coloured." Hence, in botany, a white flower is said to have colour.

—— (*Build.*) In the builder's use of the word, to "colour" is to paint either in oil or distemper: the term is applied chiefly to work on walls or ceilings.

—— (*Phys.*) The sensation of colour is due to the effect (or sensation) produced upon the retina of the eye by light of some particular wave length (*q.v.*), or by a mixture of light of several wave lengths. The sensation is only produced by light whose wave length varies from about ·00003938 cm. to ·00007594 cm. Waves lying outside these limits are not detected by the eye, though they may be detected by other means, such as their thermal or their chemical effects. A given colour can only be fully described by means of three properties which it possesses: (1) HUE or Tint, (2) LUMINOSITY, and (3) PURITY. The first of these depends on its frequency, and is analogous to the Pitch (*q.v.*) of a sound; the second depends on the amplitude of the vibrations, and is analogous to the Loudness of a sound; the third depends upon its freedom from admixture with white light, and is to some extent analogous to the Timbre or Quality of a sound. The colour of an object is due to the light which it sends to the eye; accordingly, in the case of a body which is not self-luminous, the apparent colour will depend upon the nature of the light by which the body is illuminated; it is therefore not an inherent property, and will vary when the object is viewed by different kinds of light. In ordinary language, the colour of a body means that particular colour or hue which it sends to the eye when it is illuminated by sunlight, either direct or diffused. *See also* COLOURS (*Pigments*), SPECTRUM, SPECTRUM ANALYSIS, *etc.*

Colour Base (*Chem.*) The name given to a basic substance which is itself colourless, but whose salts are dyes. Thus triamidotriphenyl carbinol,

$$\begin{matrix} H_2NC_6H_4 \\ H_2NC_6H_4 \end{matrix} > \underset{\displaystyle OH}{\overset{}{C}} - C_6H_4NH_2$$

is colourless, but its salts are dyes of an intense red colour.

Colour Blindness (*Light*). The inability of a person to distinguish one colour from another. It corresponds to the lack of a "musical ear," which is the inability to distinguish tones or sounds of different frequencies. Both these defects are usually partial only; a colour-blind person is as a rule able to distinguish certain colours, but not all.

Coloured Screens (*Photo.*) *See* PHOTOGRAPHY IN COLOURS *and* ISOCHROMATIC PHOTOGRAPHY.

Colouring (*Paint.*) A term used with reference to the manner or style in which the colours have been handled in a painting, but more especially with reference to the general effect produced by the colours employed. *See* COLOURIST.

Colourist. A painter who excels or who aims at excellence in colouring, *i.e.* brilliance and harmony. The painters of the Venetian School, notably Titian and Veronese, excelled as colourists, as also did

Velasquez, Rubens, Rembrandt, Eugène Delacroix, Constable, and, in recent times, some members of the pre-Raphaelite School.

Colourless (*Botany*). A green part of a plant is said to be colourless. *See* COLOUR (*Botany*).

Colour, Local. Tone or colour appropriate to a particular object in a picture: realistic representation of scenes, with proper accessories.

Colour Photography. *See* PHOTOGRAPHY IN COLOURS.

Colour Printing. *See* PRINTING; CHROMOLITHOGRAPHY, *under the head* LITHOGRAPHY; *and* CHROMOXYLOGRAPHY, *under the head* ENGRAVING (CHROMOXYLOGRAPHY).

Colours (*Pigments, Dec., etc.*) The word colour is commonly applied to pigments used for imparting colour to various objects. The study of this subject is a very complex one, and is surrounded by many difficulties, not the least of which is the fact that the colour sense varies largely in different individuals, while about one person in eighteen is partially colour blind, *i.e.* cannot distinguish between certain different colours. There is no settled nomenclature for colours, and this adds to the difficulty. A consideration of colour may conveniently be divided into two distinct parts, one relating to colour in the scientific sense (*see* COLOUR), and the other the colour of the artist, dyer, and house painter. Colour has no concrete existence, but must be considered merely as a sensation. A plant, for example, which is of a bright green colour when viewed in the daylight. loses that colour wholly when taken into a dark room. All objects are seen by rays of light reflected from such objects on the retina of the eye by means of a set of lenses. Certain nerves susceptible to colour are excited at the same time, so that a perfect picture as to form, colour, and shading is produced. Ordinary sunlight is not simple, but complex, consisting of all the colours in combination. This was first demonstrated by Newton in his classical experiment. He pierced a hole through the closed shutter of a window upon which the sun was shining, so as to admit only a beam of sunlight. Having placed a glass prism in the path of this beam, he obtained a spectrum (*q.v.*), having upon it all of the colours of the rainbow, each merging into the other immediately adjacent to it. He thus established the fact that white light is composed of a number of beams or rays of coloured light. The splitting up or refraction of light in order to produce all the colours in a spectrum may be done in various ways on a scientific basis, such as by a glass prism, a diffraction grating (*q.v.*), etc. In each case the spectrum is essentially the same, including, first, red, then red-orange, followed by orange, orange-yellow, yellow, green-yellow, yellow-green, green, blue-green, cyan blue, blue, blue-violet, and violet. We have thus a series of colours, one merging into the other, and giving a very great variety of hues. Indeed, it is probable that a sensitive eye can distinguish between some two million different colours. No doubt the power to distinguish the small differences in hue is a matter of cultivation. Savages are probably able to distinguish only the most striking differences, such as the bright reds, greens, and yellows. It is probable, too, that in the early history of mankind the eye was uncultivated, and that it is among cultured people that the greatest sensitiveness in distinguishing colours is found Insects are without doubt susceptible to colour and it is here that nature causes colour to play a useful part; *e.g.* the hue of the petals of a flower is such as to attract (in conjunction with the perfume) the fertilising insects. If any colour in a spectrum be separated from the rest (this can be readily accomplished by piercing a screen upon which the spectrum is thrown), and if this single colour is allowed to pass through a second prism, it will be found that it may again be divided up, excepting in the case of red, green, and violet, which remain unchanged, and are therefore termed the three PRIMARY COLOURS. As will presently be explained, these primary colours do not correspond with what were formerly accepted as primaries, *viz.* red, blue, and yellow, the latter being based upon the results obtained from the admixture of pigments. If three magic lanterns are fitted respectively with red, green, and violet glasses of exactly the right hue, and the beams of these different coloured lights are allowed to fall upon the same spot on a screen, white will be the result. There is some difference of opinion as to the exact hue of the three primary colours named, but the consensus of opinion is that the red is similar to that produced by the admixture of carmine and vermilion (the well known post office red, for example), while the green is emerald green (*q.v.*), and the violet somewhat bluish in hue. The most convenient method of considering the differences in effect produced by coloured lights or coloured pigments or dyes is to consider that such pigments or dyes are not the colours themselves, but the bodies which produce the sensation of colour. The accepted theory is that when white light falls upon a green plant, for example, all the rays are absorbed excepting the green rays, which are reflected to the eye. When admixtures of coloured light are made, either by means of magic lanterns or by revolving discs, the result is very different from the admixture of the same coloured pigments. Thus red and green light when mixed give yellow, but red and green pigments yield a brown. Blue and yellow lights give a greyish white, while, as is well known, blue and yellow pigments give a green. In dyes the difference is even more striking. David Paterson gives a number of instances—*e.g.* red and yellow-green in dyes give a terra-cotta shade when mixed, but in the case of light a very pale pink; a deep shade of red and green in dyes yields black, and in coloured lights a grey. Blue and red dyes produce a deep red or maroon, but in light a violet purple. The same difference is apparent in house painters' and artists' pigments. For example, a mixture of yellow and black gives a good neutral green. It should therefore be considered that the admixture of pigments changes their qualities by the absorption of light, or at least the reflected rays are, in the aggregate, changed, and hence the appearance is different. In practical work the mixture of coloured light is generally discarded, although a knowledge of the subject is essential to its investigation. When different colours are arranged side by side in minute quantities, and are viewed from a distance, the rays of light reflected from each combine, giving practically the same result as would be obtained, not from an admixture of the different coloured pigments employed, but of the lights they represent. Colour printers frequently combine colours in the same way, as, for instance, in producing a series of red tints by "ruling up," or introducing very fine white lines between the coloured ones. It is stated that experiments conducted recently with a view to ascertaining which colours may be most advantageously employed for painting guns so as to render them least con-

spicuous to the enemy, resulted in the discovery that if the primary colours were used in dots and in the proper proportion they would, when viewed at a distance, be almost invisible, the explanation being that the light of the three colours reflected over a long distance combined so as to form a white light, and consequently the gun was rendered practically invisible. It has already been stated that the three primary colours or sensations are red, green, and violet; the three primary pigments are usually red, blue, and yellow, and it will be observed that the term "red" is used in both cases. It need hardly be pointed out that "red" does not refer in each case to the same colour, which is another illustration of the inconvenience which arises from a want of nomenclature of colours. If the position of the six colours, *viz.* the three primary pigmentary colours and the three primary colours of light or sensations, be taken from a spectrum, it will be found that they do not coincide. The red pigment is of a somewhat violet hue, while the red colour light is a distinct orange hue, and this explains the whole difference. We may thus set out the colours as corresponding with the spectrum: Red (pigment), red (sensation), yellow (pigment), green (sensation), blue (pigment), violet (sensation). The study of complementary colours is one which is of the utmost interest in the solution of problems relating to colour harmony, and is indeed the foundation upon which a study of the subject is founded. Speaking broadly, a complete colour harmony may be said to consist of such a combination of all the colours as, when viewed as a whole, one set of colours tends to neutralise the others. Thus the eye is not unduly excited by a single colour, or excess of a single colour, as it would be when the combination was out of harmony. A room painted in a single colour becomes distressing to the eye, because it unduly excites the nerves of that particular colour, which soon become tired. Setting down the above-mentioned primary colours in regular order, and calling the "red" of the colour sensation "orange," we have the following table:

PRIMARY COLOURS. *Pigments.*		PRIMARY COLOURS. *Sensations.*
Blue is complementary to	.	Orange.
Red is complementary to	.	Green.
Yellow is complementary to	.	Violet.

If the spectrum be so arranged as to form a circle, that is, the red joining the violet, there will be found to be no distinct break between the two, the red merging into the violet, as might be expected. A colour circle of this kind can be used by the decorator to ascertain at a glance the colour complementary to any other colour. For example, a bright crimson red immediately faces, or is opposite to, emerald green, and this emerald green consists of a mixture of blue and yellow; hence we have the three colours which form in theory white, or a combination of all the colours in one. COLOUR MIXING: Although the general understanding is that all colours may be made from an admixture of red, blue, and yellow pigments, yet in practice it is found convenient to use a much more extended palette. Speaking generally, it may be said that the more expert a mixer is the fewer number of palettes he will require. The palettes of well known artists differ exceedingly, and each shows some individuality. Professor Church gives the following palettes: Sir Joshua Reynolds, (1) Flake white, yellow ochre, lake, ultramarine, black. (2) Flake white, Naples yellow, yellow ochre, carmine, vermilion, ultramarine, and black. Sir John Gilbert, R.A. (fifteen pigments), Chinese white, yellow ochre, raw sienna, vermilion, light red, Venetian red, Indian lake, cobalt, artificial ultramarine, indigo, Prussian blue, Antwerp blue, burnt sienna, Vandyke brown, ivory black. Church gives the following selection as a general working set for oils of twelve pigments: Flake white, cadmium, yellow aureolin, yellow ochre, vermilion, madder, carmine, light red, viridian, artificial ultramarine, raw umber, cappagh brown, and ivory black. By way of a contrast, the palette of the Hon. John Collier may be given. This is as follows: Flake white, raw sienna, yellow ochre, orange vermilion, Chinese vermilion, rose madder, burnt sienna, emerald oxide of chromium, cobalt blue, ivory black, and raw umber. Many artists' primary consideration is obviously the permanent character of the pigments employed and the avoidance of those which will destroy one another. With house painters the cost is of much greater importance. The earth colours, such as siennas, ochres, and umbers, and the cheaper colours, such as Prussian blue, ultramarine (artificial), and the chromes are used freely with small quantities of vermilion, black, and the finer colours. The house painter obtains a series of reds by using either vermilion or its equivalent, known as fast red, mixed with either white ochre or Venetian red. His blues are mostly produced from ultramarine and Prussian blue, the former being discarded when the base is white lead, owing to the fact that it is adversely acted upon because of the sulphur it contains. In yellows he has a variety of different shades of chrome yellows, ranging from a very light "canary" to a deep orange, which is almost red. Cadmium yellow (*q.v.*), although expensive, is most useful, while zinc yellows are also used to some extent, owing to the fact that they are not affected by impure air, as the chromes are. Drabs, fawns, and light browns generally are easily obtained from a mixture of French ochre or Italian sienna, mixed with white lead, a little Indian red, Venetian red or black being introduced where necessary to give variety. The brilliancy of a colour in house painting is frequently added to by the process known as GLAZING (*q.v.*), or giving a coat of transparent colour over a suitable ground, such, for instance, as sienna and lake on a less vivid but solid colour. *See also* HUE, TINT, SHADE. A. S. J.

Colours, Blended (*Paint.*) The harmonious effect produced by the gradual blending of one tone or colour with another.

——, Complementary. Two colours are complementary to each other if, when mixed, they make white. It is to be noted that this is true of COLOURS, but not of pigments. *See* COLOURS (*Pigments*).

——, Heraldic. *See* HERALDRY.

Colour, Shot (*Textiles*). A material woven in various colours in such a manner that when observed at different angles the colours appear to change.

Colours of Thin Films (*Light*). Brilliant colours are given by any sufficiently thin transparent film, *e.g.* a film of oil floating on water. The colours are due to interference (*q.v.*) between light waves reflected from the two surfaces of the film. The colours vanish, however, if the thickness of the film become small compared to the wave length of the light falling upon it, and the film then appears black.

Colours, Primary (*Light*). A primary colour is one which cannot be produced by the mixture of any

two (or more) different colours. The colours usually accepted as the primaries are Red, Green, and Blue; but there are reasons for considering that Violet is primary, rather than Blue. The question of primary colours was first studied by artists, who decided that they were Red, Yellow, and Blue, as it was impossible to produce *pigments* of either of these hues by the admixture of any two other pigments. But a pigment owes its hue to a combination of the processes of reflection and absorption, and experiment has shown that green, and not yellow, is a true primary. *See also* COLOURS (*Pigments*).

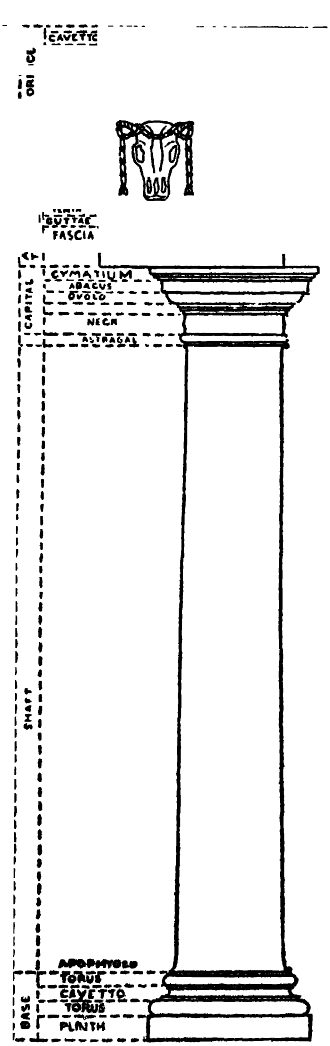
Colours, Prismatic. *See* SPECTRUM *and* SPECTRUM ANALYSIS, *etc.*

——, Secondary (*Paint.*) Colours resulting from a mixture of two of the so-called primary colours (*q.v.*), or, more correctly, pigments of these colours. They are Orange, obtained from red and yellow; Green, from blue and yellow; Purple, from red and blue.

——, Tertiary (*Paint.*) Various grey colours produced by the mixture of two secondary colours (*q.v.*), such as red-grey, blue-grey, yellow-grey; or violet-grey, green-grey, orange-grey, according as the primaries or secondaries are in excess.

Columbier. Drawing paper about $34\frac{1}{2} \times 23$ in. in size.

Column (*Architect.*) A vertical support of considerably greater length than thickness. In Greek, Roman, and Renaissance work the column is one of the chief divisions of the order, and is again subdivided into three parts, the base, shaft, and capital, except in the case of the Greek Doric order, in which the column has no base. *See* ARCHITECTURE, ORDERS OF: DORIC, IONIC, CORINTHIAN, TUSCAN, COMPOSITE, ENGAGED COLUMN, *and* CABLED COLUMN.



COLUMN: ROMAN DORIC.

—— (*Eng., etc.*) A vertical support subjected to compression. An overloaded column almost invariably fails by bending, not by crushing, of the material, and therefore the column should be designed to resist flexure; *i.e.* the MOMENT OF INERTIA (*q.v.*) of its cross section should be as large as it can conveniently be made. This is best effected by making the column hollow. A given weight of material then forms a much stiffer support than it does if made into a solid column.

Columnar Structure (*Geol.*) A rock structure which takes the form of polygonal columns, often hexagonal in outline. It is clearly traceable to the effect of cooling, upon a rock which has been at a high temperature; and the longer axes of the prisms or columns usually extend at right angles to the surfaces of cooling. It is often developed to a remarkable extent in basalts; but it is by no means of rare occurrence also in coal seams, in clays, or in sandstones, which have been exposed to heat.

Colza Oil *or* **Rape Oil.** Colza oil is obtained from the seed of the Rape plant, *Brassica napus* (order, *Cruciferæ*), by pressure. The residue forms OIL CAKE, used for feeding cattle. The oil is largely used for lubricating and illuminating purposes, and in lesser quantities for making soft soaps and blacking. When employed for lubricants it is usually thickened by blowing. *See* BLOWN OIL. It possesses a characteristic taste and smell, and when refined is pale yellow; sp. gr. 0·912 to 0·920 at 60° F.

Comb (*Bind., Dec.*) An instrument with wire teeth used in MARBLING (*q.v.*); it is also used in decorators' work. *See* COMBING *and* GRAINING.

Comb Bar (*Lace Manufac.*) A very accurately shaped and finished bar of iron, in some cases faced with brass, upon which the "comb leads" are screwed side by side, thus forming a continuous series the width of the machine.

Combed Yarns (*Cotton Spinning*). A good quality of spun yarn, usually Egyptian or Sea Island Cotton, which has undergone the combing process in addition to CARDING (*q.v.*)

Comber Board (*Cotton Weaving*). A length of wood or a number of wood slips placed in a frame. They contain finely bored holes, through which are passed the harness thread or coupling of a Jacquard. Used for keeping threads and couplings in position and determining their set or closeness. Also termed COMPASS BOARD.

—— (*Silk Manufac.*) Slips of wood framed together to width of figured harness, and perforated with holes disposed in lines through which the couplings or lashes carrying the mails and lingoes in mounture are led. From this point they are connected by necking cords with the Jacquard machine.

Combination (*Lace Manufac.*) A term used in the manufacture of lace curtains, signifying that a more complex movement of the threads has been necessary than in the case of ordinary curtains.

Combination Tones (*Sound*). Tones or notes sometimes heard when two notes which produce beats are sounded together. Their frequencies are either the sum or the difference of the frequencies of the two separate tones which are being sounded. In the first case the tone is termed a SUMMATION TONE, in the second a DIFFERENCE TONE. In certain circumstances, additional combination tones, termed BEAT TONES, may also be detected.

Combined Carbon (*Met.*) Carbon chemically combined with iron occurs in cast iron and steel, some form of binary compound—a CARBIDE (*q.v.*) —probably being formed. *See also* IRON.

Combing (*Cotton Spinning*). Combing is a very important and necessary process where fine yarns of good quality are required to be spun. The object is to eliminate all fibres under a certain length, so that those remaining may be uniform and placed parallel, thus producing a regular and clean sliver. The most successful is the Heilmann comber. Others in use are Hübner's, Imb's, Staub & Montford's, Delette's, Gegauff, Nasmith's.

—— (*Dec.*) Graining done with a comb, a flat flexible metal plate divided up into parallel tongues. *See also* GRAINING.

—— (*Woollen Manufac.*) The process of straightening fibres of materials, *e.g.* wool, mohair, alpaca, and cotton, in which the short and nappy fibre is removed. The straightened material forms the TOP, and the extracted fibres the NOIL.

Combining Weights *or* **Combining Proportions** (*Chem.*) The proportions in which elements or compounds enter into reaction with each other. These proportions are either the same as the atomic or molecular weights or some simple multiple or submultiple of these.

Combs (*Lace Manufac.*) In a lace machine, thin strips of iron, brass, or steel, segmental in shape, forming grooves on which the carriages work.

Combustion (*Chem.*) The chemical union of substances when this "union" is accompanied by the evolution of light and heat.

Combustion Chamber (*Eng.*) (1) The part of a furnace or boiler flue where the major part of the gaseous products are burnt. (2) The part of a gas (or oil) engine in which the explosion of the charge occurs.

Combustion, Spontaneous. *See* SPONTANEOUS COMBUSTION.

Come Prima (*Music*). As at the beginning.

Comets (*Astron.*) Bodies consisting of or analogous to swarms of METEORITES (*q.v.*) which describe a parabolic or elliptic orbit round the sun. Comets moving in space outside the solar system have no luminosity; but this is developed as they approach the sun, and the mass gradually becomes differentiated into a dense bright part, the NUCLEUS, and a streaming TAIL pointing away from the sun. The spectrum of a comet shows that its luminosity is not entirely due to reflected light; the increasing luminosity as it approaches the sun is due to increased activity, resulting in increased temperature, and is accompanied by modifications in its spectrum.

—— (*Her.*) A star of six points with a fiery tail.

Comma (*Sound*). The difference between a MAJOR TONE (the interval $\frac{9}{8}$) and a MINOR TONE (the interval $\frac{10}{9}$); that is, the interval $\frac{81}{80}$.

—— (*Typog.*) A punctuation mark: thus ,

Commercial Uses of the Microscope. *See* MICROSCOPE, COMMERCIAL USES OF.

Common Colours (*Dec.*) In painters' work, common colours are defined as white, black, red, umber, ochre, etc. No "art shades" or colours other than simple ones in ordinary use are included.

Common Joists (*Carp., Build.*) The ordinary JOISTS (*q.v.*) to which the floor boards are nailed; they rest on the WALL PLATES (*q.v.*) or on other joists termed BINDERS. *See also* FLOORS.

Common Salt (*Chem.*) *See* SODIUM CHLORIDE, *under* SODIUM COMPOUNDS.

Common Time (*Music*). That rhythm which has the accents occurring alternately. Originally marked by a semicircle thus, C, to distinguish it from TRIPLE TIME (*q.v.*) It is now printed thus, $\mathbf{C}$.

Communicable Disease. *See* INFECTIOUS DISEASE.

Commutator (*Elect. Eng.*) The device by which an alternating current produced in the rotating coils of the armature of a dynamo is converted into a unidirectional or continuous current in the rest of the circuit. In the simplest possible case, where the armature carries one coil only, the commutator consists of two segments, forming the two parts of a SPLIT RING. The segments are insulated from direct contact with each other, but each is connected to an end of the coil. In actual practice the armature always contains a number of coils, and these are connected to the corresponding segments or BARS of the commutator. The bars are strips of copper or phosphor bronze, arranged round the surface of a drum or cylinder fixed on the shaft of the armature, and insulated by means of mica, vulcanised fibre, etc. *See also* DYNAMO.

Comodo (*Music*). Conveniently, moderately.

Companionship (*Typog.*) A number of compositors working under the management of a CLICKER (*q.v.*)

Comparator (*Phys.*) An instrument for comparing a given scale of lengths with a Standard Scale. It consists essentially of two READING MICROSCOPES (*q.v.*) fixed accurately at a given distance apart, this distance being kept absolutely constant during the observations.

Compass. An instrument used for describing circles and for taking measurements. *See* BEAM, BOW, HAIR, TRIANGULAR, PROPORTIONAL COMPASSES; *see also* CALLIPERS *and* ELLIPTIC TRAMMEL.

—— (*Music*). The range of sounds that can be produced by a voice or instrument; it is measured by the interval between the highest and lowest notes.

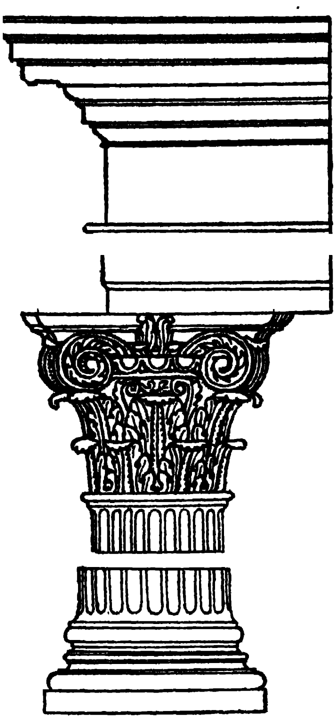
Compass Board (*Cotton Weaving*). *See* COMBER BOARD.

Compass, Magnetic (*Elect.*) A magnetic needle (*q.v.*) mounted on a fine pointed pivot in a suitable case: a card, graduated into degrees and having the cardinal points (*q.v.*) marked upon it, is fixed to the case underneath the needle. In the FLOATING CARD COMPASS the card is attached to the needle, so that the diameter joining the points marked N. and S. makes an angle with the needle equal to the magnetic declination (*q.v.*) The card and needle are so mounted as to turn together; then, when the needle comes to rest in the magnetic meridian, the abovementioned diameter will lie in the true geographical meridian. The floating card compass is very convenient for use in an area over which the magnetic declination (*q.v.*) is constant.

Compass Saw (*Carp.*) A narrow straight saw for cutting curves.

Compensated Pendulum (*Phys.*) A pendulum provided with some means of maintaining a constant length during changes of temperature, *i.e.* of counteracting the expansion or contraction of the rod. *See* PENDULUMS (HARRISON'S AND GRAHAM'S).

Compensating Collars (*Eng.*) Rings or collars, on a shaft, that can be adjusted so as to take up "wear." They are used especially in those machines in which there is a longitudinal thrust on the shaft, *e.g.* in a drilling machine.



COMPOSITE ORDER (*Architect.*)

Compensating Gear (*Motor Cars*). DIFFERENTIAL GEAR (*q.v.*)

Compensation Balance (*Watches, etc.*) A balance designed to correct the errors in time due to variations in the temperature.

Complement. The difference between an angle and 90° (*i.e.* a right angle) is termed the Complement of the angle.

Complementary Bows (*Meteorol.*) *See* RAINBOWS.

Complementary Colours. *See* COLOURS, COMPLEMENTARY.

Complete Combustion (*Eng., etc.*) A process in which all the carbon and other oxidisable constituents of a fuel are fully oxidised; that is, burnt up or combined with the maximum amount of oxygen.

Compo (*Build.*) Mortar made of cement and sand: the term is, of course, a builder's abbreviation of COMPOSITION.

Component. (1) A single separate part of a machine or structure. (2) In theoretical mechanics the components of a force are the various separate forces which, acting together, would produce the same result as the given force. A force may be split up into any number of components.

Components (*Cycle*). Parts of a cycle such as the brackets, hubs, cranks, and pedals which are sold machined and finished ready for building up the frame and wheels; they are the parts which a small maker cannot profitably make for himself, owing to the lack of elaborate machinery.

Compony *or* **Gobony** (*Her.*) A border or other ordinary divided into alternate tinctures.

Compo Pipe. Small gaspiping, composed of an alloy instead of pure lead.

Compose (*Typog.*) To set up type for printing.

Composing Frame (*Typog.*) A frame standing about breast high, on top of which the type cases in use rest at different angles. The lower part of the frame contains racks for holding cases not in use.

Composing Machine (*Typog.*) A mechanical contrivance for setting up type. The LINOTYPE (*q.v.*) is one of the best known examples.

Composing Rule (*Typog.*) A brass RULE (*q.v.*) laid in a composing stick, and against which the type is set: it facilitates the process and is shifted as each line of type is completed. Known also as a SETTING RULE.

Composing Stick (*Typog.*) An implement in which the compositor sets type. It has an adjustable part which allows the line of type to be set to the length required.

Composite Order (*Architect.*) A Roman modification of the Corinthian order, consisting of a combination of the Ionic and Corinthian capitals, the other features of the Corinthian order being little changed. *See* ARCHITECTURE, ORDERS OF: CORINTHIAN *and* IONIC.

Composite Truss (*Build.*) A TRUSS (*q.v.*) composed of wood and iron or wood and steel. *See also* ROOFS.

Composition (*Fine Arts*). The combination of the several parts of a subject in such manner that each part is in harmony with and subordinate to the whole, the subject being so presented as to be both easily understood and agreeable.

Composition of Forces (*Mechanics*). The process of finding what single force (or RESULTANT) would, if acting alone, produce the same effect as a given number of separate forces (the COMPONENTS). *See also* GRAPHIC STATICS.

Composition Pedals (*Music*). A mechanical contrivance for changing the STOPS (*q.v.*) on organs.

Compositor (*Typog.*) One who sets or composes type.

Compound (*Chem.*) A substance composed of two or more elements, chemically united; *i.e.* so united as to produce a new substance, whose chemical and physical properties differ from those of its constituents.

Compound Engine (*Eng.*) A steam engine in which steam is partly expanded in one cylinder and then allowed to enter a second (or low pressure cylinder), in which it is further expanded. A third or even fourth cylinder may be added, the engine being then termed a TRIPLE or QUADRUPLE EXPANSION ENGINE.

Compound Harness (*Cotton Weaving*). A method of mounting or tying up HARNESSES (*q.v.*) on a Jacquard, by which economy is anticipated either in labour, designing of patterns, or cost of pattern cards. There are several forms, the following being the chief: (1) Bannister; (2) Damask; (3) Double cloth or split; (4) Quilting; (5) Tapestry.

Compounding (*Eng.*) The addition of a low pressure cylinder to an engine which previously possessed a high pressure cylinder only. By this means an additional amount of useful work may be obtained which was previously wasted when the steam was allowed to escape at a high pressure.

Compound Levers (*Eng., etc.*) A system or train of levers in which the short arm of one lever acts on the long arm of the next. It is used in large weighing machines and in some testing machines.

Compound Microscope (*Light*). A combination of lenses in which a real and magnified image of an object is formed by one lens (or set of lenses) of short focal length, called the OBJECTIVE; this real image is viewed by a second lens (or set of lenses) called the EYE PIECE, which forms a magnified virtual image of the first image. By this means very high magnification is obtained.

Compound Oils (*Eng., etc.*) A mixture of several oils, which is sometimes used for lubricating. Thus a mineral oil is added to an animal or vegetable oil in order to prevent the latter from becoming too viscous, or in order to prevent decomposition.

Compound Pendulum (*Phys.*) *See* PENDULUM.

Compound Radical (*Chem.*) A group of elements entering into and being expelled from chemical combination like a single element. Thus the groups (CN), (CH_3), (OH) are compound radicals; they form chlorides, hydroxides, etc., like an element.

Compound Table (*Eng.*) A TABLE (*q.v.*) of a machine tool to which motion in two directions can be given: a third motion, one of rotation, is sometimes provided for.

Compound Time (*Music*). *See* TIME.

Compound Train (*Eng.*) A series or set of toothed wheels used on screw-cutting lathes in which there are two or more wheels connecting those on the mandrel and the leading screw of the lathe.

Compound Winding (*Elect. Eng.*) *See* DYNAMOS.

Compressed Air (*Eng.*) Used for driving machinery, for ventilating, or for excluding water in mines, tunnels, and submarine workings. The air is compressed by large pumps, driven by power, in a central engine house, and is led through pipes to the machines. In mining operations the exhaust air, after leaving the machines, helps to ventilate the workings.

Compressed Gases. Various gases can now be obtained compressed into steel cylinders under very high pressure, which may be as much as 1800 lb. per square inch or even more. Large quantities of oxygen and hydrogen are sent out in this way for use with the oxyhydrogen light and for other scientific and commercial purposes. Chlorine (used in gold extraction), carbon dioxide, ammonia, sulphur dioxide, etc., can also be obtained in this form.

Compressed Steel (*Eng.*) Ingots of steel which have been allowed to solidify under pressure. By this means the steel becomes homogeneous, and its strength is very greatly increased.

Compressibility of Gases (*Phys.*) Gases can be compressed to an enormous (though not unlimited) extent. The relation between the pressure and volume is in accordance with Boyle's Law (*q.v.*) so long as the pressure is not too great. *See also* ELASTICITY.

Compressibility of Liquids (*Phys.*) This is very slight, and can only be detected at all by very careful experiments. For practical purposes (in engineering, etc.) it can always be neglected entirely.

Compressibility of Solids (*Phys.*) This varies greatly: it is very small, and therefore may be neglected in the case of metals and many elementary substances, but with substances of complex constitution or of organic origin (such as wood, cork, rubber, etc.), it may become very considerable. *See also* ELASTICITY.

Compression (*Phys., Eng., etc.*) (1) The reduction of the length or other dimensions of a body by the application of external force. (2) The CUSHIONING or shutting in of a small amount of steam in a cylinder just before the return stroke after the exhaust port is closed. (3) The reduction in volume of the charge in a gas engine by the back stroke of the piston before the ignition or firing of the charge. This compression of the charge greatly increases the efficiency of a gas engine, as can readily be found by experiments. In modern engines the charge is often compressed till its pressure is over 80 lb. per square inch.

Compression Engines (*Eng.*) Gas engines in which the charge is subject to compression (*q.v.*) This is now adopted in practically all gas engines.

Compression Line (*Eng.*) *See* INDICATOR DIAGRAM.

Con Amore (*Music*). With love, lovingly.

Con Anima (*Music*). With soul.

Con Brio (*Music*). With brilliancy.

Concave Lens (*Light*). A lens thinner in the centre than at the edges. One face must be concave, the other may be plane, concave, or convex; if the latter form is used, its centre of curvature must be more distant from the lens than that of the concave surface. The focal length of a concave lens is a positive quantity.

Concave Mirror (*Light*). A reflecting surface which is usually a part of a hollow sphere. This does not bring a parallel beam to a true focus. (*See* SPHERICAL ABERRATION.) A PARABOLIC MIRROR (*q.v.*), which has a true geometrical focus, resembles a spherical mirror very closely as far as appearance goes; but its cross section is a parabola instead of a circular arc, thus making it somewhat flatter towards the circumference than a spherical mirror.

Concentric Chuck (*Eng.*) A SELF CENTERING CHUCK (*q.v.*)

Concertina. *See* MUSICAL INSTRUMENTS, WIND (KEYED).

Concord (*Music*). A chord requiring neither preparation nor resolution.

Concordant Intervals (*Music*). Are the perfect eighth, fifth, and fourth, and the major and minor third and sixth; also called CONSONANCES.

Concordant Tones (*Sound*). Two notes or tones which, when sounded together, produce no sensation of roughness or discord due to beats. This is not the same thing as the absence of beats; they may be present, but not sufficiently prominent to be detected by the ear.

Concrete (*Build.*) A mixture of lime or cement mortar with some coarse material, such as broken bricks, stones, slag, coke, etc. It is much used for foundations, heavy masonry, paving and in many kinds of building and civil engineering work.

Concretionary Structures (*Geol.*) These are due in all cases to chemical action; but the precise condition under which these forces act is at present very imperfectly understood. Solutions of various substances that happen to be present in a rock tend to concentrate around some nucleus, which is not uncommonly of organic origin, and the process of aggregation often goes on until the whole of the substance which happens to be within migrating distance of the nucleus has drained from the

surrounding rock and has collected around that point. Flints, nodules of chert, and clay ironstone are familiar examples of concretions.

Condensation (*Chem.*) The union of two or more molecules, which may be the same or different, to form a new molecule, the occurrence generally, but not always, being accompanied by the splitting off of water, alcohol, etc. Substances which induce this kind of change are called CONDENSING AGENTS. Example of condensation :

$$\underset{\text{Aldehyde.}}{CH_3.CHO} + CH_3CHO = \underset{\text{Aldol.}}{CH_3CHOH.CH_2CHO}$$
$$= \underset{\text{Croton aldehyde.}}{CH_3CH:CH.CHO} + H_2O$$

Examples of condensing agents are zinc chloride, hydrochloric and sulphuric acids, aluminium chloride.

—— (*Phys.*) The reduction of a gas or vapour to its liquid form by cold or pressure or both combined. *See also* LIQUEFACTION OF GASES.

Condensed Thread (*Textile Manufac.*) *See* SLIVER.

Condenser (*Light*). A MICROSCOPE CONDENSER is a lens used to produce powerful illumination of the slide or other object which is being viewed. A LANTERN CONDENSER, on the other hand, is not required in order to increase the intensity of illumination of the slide, but to cause the rays to converge after passing through the latter, so that they may also pass through the remaining lenses, which focus the picture on the screen.

—— (*Phys., Eng., etc.*) Any arrangement for condensing gases or vapours. In a steam engine the arrangement for condensing the steam by bringing it into contact with either cold water or a cold surface. The former arrangement, which was the one first used, constitutes an INJECTION or JET CONDENSER; the latter, which is generally used in steamships, is known as a SURFACE CONDENSER (*q.v.*)

—— (*Cotton Spinning*). A machine used in the spinning of coarse waste yarns, attached to a carder for the purpose of splitting up the web from the doffer into strips, and at the same time rolling it into a round strand preparatory to the spinning process. The yarns are called CONDENSER YARNS. *See* CARDING.

—— (*Gas Manufac.*) *See* GAS MANUFACTURE.

—— (*Woollen Manufac.*) The delivering section of a set of carding engines that divide the endless fleece of fibres into soft fluffy threads. *See* CARDING.

——, **Electrical.** Any two conducting surfaces separated by a DIELECTRIC (*q.v.*) A sheet of glass coated on both sides with tinfoil, or a pile of alternate sheets of tinfoil and mica, are common forms. Condensers are used as standards of electrical capacity in various quantitative experiments, and are also used in Induction Coils, Tesla Coils, etc. (*q.v.*)

Condenser Tubes (*Eng.*) Tubes used in SURFACE CONDENSERS (*q.v.*); they are usually brass, ¾ in. and upwards in diameter.

Condensing Agents (*Chem.*) *See* CONDENSATION (*Chem.*)

Conditioning (*Cotton Spinning*). When yarn is taken from the spindles it usually contains about 3 per cent. less than its natural moisture. It is therefore CONDITIONED by keeping a few days in a damp place, so as to regain the loss.

Conductance (*Elect.*) The inverse of resistance: if the resistance of any conductor be r, then its conductance is $\frac{1}{r}$.

Conduction of Electricity. The passage of electricity through the material or over the surface of a body. The nature of the process is well understood in the case of liquids and gases (*see* CONDUCTIVITY OF LIQUIDS), and there are reasons for supposing that the process of conduction in solids may be of a similar nature, *i.e.* it may be due to the action of IONS (*q.v.*) The conductivity of metals is much greater than that of electrolytes, but "there does not seem to be sufficient difference between the *laws* of conduction through metals and electrolytes to make it necessary to seek an entirely different explanation for metallic conduction."—J. J. THOMSON.

Conduction of Heat. The passage of heat through matter, without visible motion of the particles. These particles are probably set in vibration, but do not move permanently from their original positions or acquire a motion of translation, as in CONVECTION (*q.v.*)

Conductivity for Heat, Coefficient of. The amount of heat which flows in unit time through unit area of a layer of substance of unit thickness when unit difference of temperature is maintained between the two sides. If k be this coefficient for any substance in the form of a plate, of area A and thickness d, and if t_1 and t_2 be the temperature at which the opposite sides of the plate are maintained, then the quantity of heat Q which flows through the plate in T seconds is given by the equation

$$Q = k\frac{A(t_1 - t_2)T}{d}.$$

Conductivity of Liquids (*Phys.*) As a rule the electrical conductivity of liquids depends upon charges of electricity being carried through the liquid by the formation of IONS (*q.v.*) in the liquid. These are atoms, or groups of atoms, into which substances in solution or liquid are broken up by the action of the electricity. Water, if pure, conducts little, if at all; but the addition of any substance which can be split up into ions, such as a mineral, acid, or salt, renders it a good conductor. This process is thus analogous to CONVECTION (*q.v.*)

Condy's Fluid (*Chem.*) A liquid prepared by adding potassium permanganate to aluminium sulphate solution. It is a good disinfectant.

Cone (*Math.*) A geometrical solid produced by the rotation of a triangle about one side.

—— (*Eng.*) A stepped driving pulley (*q.v.*)

—— (*Met.*) The cap or cover of a blast furnace (*q.v.*)

Cone Bearing (*Eng.*) A bearing in which a solid cone on the shaft or spindle runs in a bearing formed by a hollow cone of hard steel or brass; commonly used in lathes as a bearing for the mandrel.

Cone Clutch (*Eng.*) A friction clutch in which the respective parts of the shaft carry a hollow and a solid cone, one fitting into the other. These are caused to turn together by the friction between the surfaces when they are brought into close contact. A cone clutch can be thrown in or out of gear without any sudden shock to the mechanism with which it is connected.

Con Energia (*Music*). With energy.

Cone Plate (*Eng.*) A vertical plate fixed on the lathe bed to support the end of cylindrical work, the free end of which revolves in a tapering hole in the plate, thus dispensing with the use of the back centre, and allowing boring tools or drills to be inserted through the hole in the plate, in order to act on the work as it rotates.

Con Espressione (*Music*). With expression.

Conformable Succession (*Geol.*) Successive beds of rock which have been formed over the same spot one after the other (without any important interruption or hiatus, representing strata which have been deposited in the meantime elsewhere) are said to be in conformable succession. If an older set of rocks has undergone disturbance, so as to be tilted from its original position, then partly denuded, and another set of rocks deposited across their edges, the succession is said to be UNCONFORMABLE. The relationship implies lapse of time.

Con Forza (*Music*). With force.

Con Fuoco (*Music*). With fire : passion.

Congé (*Architect.*) *See* APOPHYGE.

Conger Eel. *Conger vulgaris* (family, *Murænidæ*). The conger is closely allied to the true eel, and its flesh is much used for making soups.

Conglomerate (*Geol.*) An indurated rock formed of rounded and sub-angular fragments of derivative origin, worn by the action of water and afterwards compacted by some cementing material. When the fragments are angular, the rock is distinguished as a BRECCIA. AGGLOMERATE is always of volcanic origin.

Congo Red (*Chem.*)

$$\begin{array}{l} C_6H_4 \underset{(4)}{-} N : N \underset{(2)}{-} C_{10}H_5 \left\langle \begin{array}{l} NH_2 \ (1) \\ SO_3Na \ (4) \end{array} \right. \\ (1) \,| \\ C_6H_4 \overset{(4)}{-} N : N \overset{(2)}{-} C_{10}H_5 \left\langle \begin{array}{l} NH_2 \ (1) \\ SO_3Na \ (4) \end{array} \right. \end{array}$$

A reddish-brown powder. The salt is soluble in water, but the free acid is only soluble with difficulty, and is blue in colour. It is obtained by union of tetrazodiphenyl—from benzidine (*q.v.*)—with α-naphthionic acid. It dyes wool or cotton red, but the colour is changed to bluish shades by acids. It is important as an INDICATOR (*q.v.*) Alkalis turn it a brilliant scarlet, while acids turn it blue : an alcohol solution must be used. It is also used as a stain in Bacteriology. *See also* DYES AND DYEING.

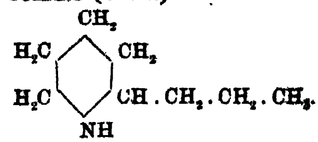
Con Grazia (*Music*). With grace.

Conical. In the form of a CONE (*q.v.*)

Conical Spring (*Eng.*) A spring produced by winding a strip of metal on the surface of a cone: often used in buffers, etc.

Conical Turning (*Eng.*) The production of taper work, usually effected by setting the loose headstock or poppet of a lathe out of the line of centres, and then taking a cut parallel to the bed with the slide rest. As the point of the tool moves parallel to the axis of the lathe bed, the surface of the work will be turned in the form of a cone. In other cases, when a short cone of large vertical angle is required, the upper part of the slide rest is set at an angle with the bed.

Conine, Coniine (*Chem.*)



An alkaloid: the poisonous principle of HEMLOCK. A colourless liquid; faint mousy odour, alkaline, dextro-rotatory, sparingly soluble in water (1 in 90). It is a powerful poison, affecting the motor nerves so that the limbs become paralysed. It is obtained by treating the juice from hemlock seeds with alkali, distilling in steam, and purifying the crude distillate. It has been prepared synthetically, and its constitution is proved by heating it with hydriodic acid, when it yields ammonia and normal octane.

Coning (*Eng.*) Forming the rims of railway wheels in the shape of part of a cone. This taper or conical form facilitates the turning of curves on the line.

Conjugate Conductors (*Elect.*) Two conductors are said to be conjugate if they are connected (by other conductors) in such a manner that an electromotive force in one of them does not produce any current in the other. *See also* WHEATSTONE'S BRIDGE.

Conjugate Foci (*Light*). Two points such that light diverging from one of them and falling on a lens or mirror, either *converges to* the second (which is then termed a REAL IMAGE of the first) or else appears to *diverge from* the second (which is called a VIRTUAL IMAGE of the first point).

Conjunction (*Astron.*) The position of a planetary body when its elongation (*q.v.*) is zero, *i.e.* when its longitude equals that of the sun; *e.g.* the moon is in conjunction with the sun at NEW MOON.

Con Moto (*Music*). With motion.

Connecting Rod (*Eng.*) A rod which transmits the motion of the piston rod to the crank pin of an engine. *See* STEAM ENGINE, *etc.*

Connective Tissue (*Zoology*). The term applied to a thin membranous tissue, consisting of irregular cells and fibres in a soft gelatinous matrix. This tissue covers and supports all the organs of the body.

Connector (*Gasfitting*). A socket on a pipe with a long thread and a back-nut; it serves to make a joint or connection between two pieces of barrel or piping, either of the same or of different diameters.

Connemara Marble. *See* BUILDING STONES.

Connoisseur. A good judge of some branch of the fine arts : one having a critical knowledge of works of art.

Consecutives (*Music*). Intervals occurring between the same parts or voices.

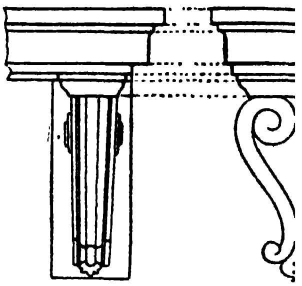
Consequent Poles (*Elect. Eng.*) Consequent poles may be regarded as poles (*q.v.*) produced by the junction of two or more similar poles; they are frequently employed in the magnetic circuit (*q.v.*) of dynamos. The magnetising coils are in pairs, one coil being on either side of each pole piece, and the magnetising forces of these two coils act in opposite directions. The effect is analogous to that produced by two cells in parallel (*q.v.*); the lines of force correspond to the electric current, and that part of the

magnetic circuit which consists of the armature and the two pole pieces corresponds to the external circuit in the case of the two cells. *See also* DYNAMOS.

Conservation of Energy (*Phys.*) Energy may be communicated from one body to another, or it may be changed from one form to another, but it can neither be created nor destroyed.

Console. A table supported by two legs placed in front, the back being fastened to the wall.

—— (*Architect.*) An ornamental bracket or corbel. *See* MODILLIONS, *etc.*



CONSOLE (*Architect.*)

Consolidation of Strata (*Geol.*) Fragmentary or clastic rocks are in some cases compacted into hard masses by the mere pressure of thick piles of other rocks which have been deposited over them. But more generally their consolidation is due to the infiltration of waters holding in solution various mineral substances which have been eventually deposited as a cement between the particles. Lime, iron, silica are common substances deposited in this way.

Consonance (*Music*). *See* CONCORD.

—— (*Sound*). The effect of CONCORDANT TONES (*q.v.*)

Con Spirito (*Music*). With spirit.

Constant (*Eng.*, *Physics*, *etc.*) A coefficient, used in various formulæ, which depends on the dimensions, form, or nature of the substance or the material to which the formula refers. A constant may either be capable of being calculated or be a quantity which can only be found by experiment.

Constant Current (*Elect. Eng.*) (1) A current whose amount or value is allowed to vary as little as possible. (2) A CONTINUOUS CURRENT, as distinguished from an alternating current, is often (though not very correctly) termed a constant current.

Constant Voltage (*Elect. Eng.*) An electrical pressure or voltage kept at a uniform value, as, for example, when it is required to supply a number of lamps in parallel, so that the actual current in each lamp does not vary, even though the number of lamps is altered. The ordinary house supply of electricity is always on the constant voltage system.

Constitution (*Chem.*) The arrangement of the atoms of the elements to form a molecule of a compound. Thus, carbon monoxide has the formula CO, as is proved by analysis and the agreement of this formula with the observed vapour density; it unites with its own volume of chlorine in sunlight, and so the most probable CONSTITUTION of the product (carbon being tetravalent) is $O = C \langle {Cl \atop Cl}$. When this gas is treated with ammonia we get hydrochloric acid and urea. Hence we infer the constitution of urea is $O = C \langle {NH_2 \atop NH_2}$.

Constitutional Formulæ (*Chem.*) *See* CHEMICAL FORMULA.

Contact Difference of Potential (*Elect.*) When two metals are placed in contact, there is a small potential difference (*q.v.*) between them, which is independent of the extent of surface in contact, but depends on the physical and chemical nature of the metals. Contact differences of potential also occur between other substances; the most important cases in practice are those of the metals and carbon in contact with various acids.

Contact Metamorphism (*Geol.*) A term applied to the changes which are brought about in rocks by the chemical action of the heated waters which are present where eruptive rocks are in process of formation. Solution of certain constituents, recombination, and incipient crystallisation result from these causes; and the process may be continued in some cases so far that more or less complete metamorphosis of the rocks affected may result. The nature of the new minerals developed by the change is largely dependent upon that of the original substances acted upon.

Contact Printing (*Photo.*) The usual printing processes in photography in which the sensitised surface is placed in contact with the negative to be copied during the exposure to light.

Contact Vein (*Mining*). A vein which occurs between two different kinds of country rock (*q.v.*)

Contagion (*Hygiene*). When disease is communicated from one person to another by actual contact, the term CONTAGION is used. It is employed in a sense distinct from INFECTION. By this latter term is meant the transmission of disease through the medium of air, food, water, etc. Some diseases are both contagious and infectious.

Contemporaneous Erosion (*Geol.*) Where sedimentary rocks are in process of formation on the land or in shallow water, it frequently happens that a portion which has only lately been deposited, may locally undergo removal. Sandbanks in deltas, or near the mouth of rivers, are particularly liable to such accidents, which may happen again and again on the same spot, even within a short space of time. Hence the phenomenon does not necessarily afford any indication of a lapse of time, as does that of UNCONFORMITY (*q.v.*)

Con Tenerezza (*Music*). With tenderness.

Continuous Alternating Transformer (*Elect. Eng.*) A combination of a motor and a dynamo, often with the armatures on the same shaft, or even with a single armature for turning a continuous into an alternating current, or *vice versa.*

Continuous Beam (*Eng.*) A beam which rests upon more than two supports. The stresses, deflection, etc., are calculated by means of the theorem of THREE MOMENTS (*q.v.*)

Continuous Brake (*Eng.*) A brake which is applied to a number of wheels simultaneously, and is controlled from one point.

Contortion of Strata (*Geol.*) Piles of strata which have been deposited in horizontal positions may be carried downward by subsidence of the earth's crust, and thus be subjected to lateral (as well as vertical) compression. A continuance of the process bends the strata into folds, which may eventually be so closely pressed together that crumpling and contortion may result. Fine examples may be met with in almost any region where the strata have undergone much disturbance.

Contour (*Art*). (1) The outline of a figure: the expression is generally used when speaking of rounded or sinuous bodies. (2) The line dividing the different coloured parts of a design.

Contourné (*Her.*) Reversed on the field, as when a beast is represented with its face towards the sinister side.

Contours (*Surveying*). Lines joining all points at the same given height above an assumed level, called the DATUM LINE or DATUM LEVEL.

Contraction. The diminution in length, area, or volume of a body, however produced.

Contraction of Area (*Eng.*) This applies specially to the diminution of the cross section of a bar at the point where it contracts in a testing machine. The greater the amount of the contraction the better the material, as a general rule.

Contraction Rule (*Pattern-Making*). A pattern-maker's measuring rule, on which all dimensions are increased in proportion to the amount of contraction which a casting will undergo in cooling: ·1 in. per foot in iron, and ·15 in. in brass, is usually provided for.

Contralto (*Music*). The lowest of the voices of women.

Convection Currents (*Heat*). *See* CONVECTION OF HEAT.

Convection of Heat. The passage of heat through liquids and gases by the actual motion of streams of heated particles, which, being lighter than the surrounding fluid, tend to rise as " Convection Currents." Convection usually plays a more important part than conduction in the spread of heat through a fluid; water, for example, is so bad a conductor that if a comparatively short column be heated at the top, the upper layers can be made to boil, while the lowest layers are kept almost at freezing point.

Converter (*Metallurgy*). *See* BESSEMER CONVERTER *and* STEEL.

Converters (*Elect.-Eng.*) TRANSFORMERS (*q.v.*)

Converting (*Metallurgy*). The manufacture of steel from wrought iron by the cementation process, but also applied to the Bessemer process (*q.v.*) *See also* STEEL.

Convex Lens (*Light*). A lens thickest in the centre. One face must be convex, the other may be plane, convex, or concave. A convex lens gives a real image of an object which is farther off than its First Principal Focus, and a virtual image of an object which is nearer.

Convex Mirror (*Phys.*) A reflecting surface, convex in form, and usually forming part of the surface of a sphere. The focal length is negative.

Cooking (*Hygiene*). The object of cooking is to render food more digestible and palatable. It also destroys any bacteria or parasites which may be present in the food. The ordinary methods of cooking are boiling, broiling, stewing, roasting, baking, and frying. All cooking utensils should be kept scrupulously clean.

Cooling (*Eng.*) The cooling of cast or forged metal work should in general be gradual, as this prevents the setting up of internal stresses and greatly increases the strength of the object.

Cooling Gas Engines. *See* PETROL ENGINES *and* GAS ENGINES.

Cooling, Newton's Law of (*Heat*). The rate at which a body cools is proportional to the difference in temperature between it and the medium in which it is placed. This law is only true when the differences of temperature are not very large.

Cooper's Ventilator (*Hygiene*). The purpose of this is to act as an outlet for the vitiated air. It is constructed on the " hit and miss " principle, and consists of several small pieces of glass fitted over similar sized openings in the pane of the window.

Cop (*Cotton Spinning*). The cylindrical form in which the yarn is built up when spun on the mule. It consists of a rounded bottom, with the top or finishing part cone shaped. There are three sizes of cop spun, *viz.* (1) Pin cop, (2) Bastard cop, (3) Twist cop.

—— (*Woollen Manufac.*) The conical form in which the yarn is spun on the self-actor (*q.v.*)

Copal. The term copal is applied to a number of semi-fossil resins, mostly derived from a tree, *Trachylobium verrucosum* (*Leguminosæ*), grown in Africa. The resin is found in the soil near the roots. It is largely used in the manufacture of the best varnishes. The most esteemed variety for this purpose is Sierra Leone copal, which requires a temperature of 400° F. to melt it. From it is obtained pale and very durable varnishes.

Copaline (*Min.*) One of the Bitumens (*q.v.*) It is a carbon compound with hydrogen and oxygen. Pale yellow, waxy, occurring in small fragments at Highgate Hill, London; also called HIGHGATE RESIN.

Cope (*Foundry*). The upper part of a mould.

—— (*Cost.*) An ecclesiastical vestment semicircular in form and resembling a cloak. It is worn by all grades of the clergy and sometimes by choirmen or cantors. Often embroidered, hooded, and adorned with orphreys, fastened by a clasp. It is distinguished from the chasuble as being processional, the chasuble (*q.v.*) being eucharistic.

Coping (*Build.*) The projecting course on the top of a wall.

Copper, Cu. Atomic weight, 63·6. A brownish red metal: melts at about 1050°: tough, malleable, ductile (sp. gr. 8·9). It is the best conductor of electricity known, and next to silver the best conductor of heat. In dry air it undergoes no change, but in moist air it becomes covered with a film of basic carbonate of copper. Hydrochloric acid has scarcely any action upon it, unless the metal is very finely divided, when cuprous chloride and hydrogen are produced. Sulphuric acid does not act upon it in the cold, but the hot concentrated acid forms copper sulphate and sulphur dioxide; nitric acid, except when very pure, dissolves it readily, forming copper nitrate and nitric oxide principally, but also some nitrous oxide and nitrogen. Copper displaces mercury, silver, and gold from their solutions. It enters into the composition of many important alloys —*e.g.* brass, bell metal, gun metal, bronze, German silver, platinoid, etc. The principal ores of copper are COPPER PYRITES, GREY COPPER ORE, CUPRITE, COPPER GLANCE, MALACHITE, AZURITE (*q.v.*); it also occurs in a free state, especially on the southern shore of Lake Superior. In Wales the metal is extracted as follows: (1) The ore is carefully roasted to expel a part of the sulphur and arsenic which is present in it, much of the iron sulphide forming iron oxide, while only a little of the copper

sulphide is oxidised. (2) This product is now melted to cause the union of the oxide of iron with silica of the ore, and slag containing copper, termed METAL SLAG, from the fourth operation is added. The result of the operation is a slag of iron silicate, termed ORE FURNACE SLAG, and a product called COARSE METAL, consisting of copper, iron, and sulphur. (3) The roasting process is now repeated. (4) The product is again melted, with the addition of ROASTER SLAG and REFINERY SLAG from the next two processes. As the result of this last fusion the METAL SLAG is produced, which is used in Operation 2, and a product called FINE METAL, WHITE METAL, or BLUE METAL obtained, which is practically cuprous sulphide (Cu_2S), with small quantities of other sulphides, such as iron. (5) This FINE METAL is now partially oxidised, then melted, when the oxides and sulphides react to produce copper and sulphur dioxide. This impure copper is called BLISTER COPPER, because its surface is blistered, owing to escape of sulphur dioxide as the metal solidifies. (6) The blister copper is now REFINED by being carefully roasted (exposed to oxidising action of air) to a certain extent and then melted. When melted, powdered anthracite is thrown on the surface, and poles of green wood are plunged into the molten metal, the object being respectively to prevent further oxidation and to reduce copper oxide, which exists dissolved in the melted metal. The refined copper is called TOUGH PITCH COPPER. If the "poling" is insufficient the metal is brittle or DRY. It is also possible to "overpole" the copper, when it again becomes brittle. All the above processes are carried out in reverberatory furnaces (*q.v.*) In America, blast furnaces of the RASCHETTE type (*q.v.*) are very largely used to produce a rich copper sulphide; and Bessemer converters (*q.v.*) are used to produce copper from the rich sulphide; but the blast is introduced at the sides. Much copper is also produced from Spanish pyrites, which have been burned by the sulphuric acid manufacturer. The burnt pyrites are roasted with common salt and then dissolved in water; to the solution zinc iodide is added to precipitate silver, which is recovered from the silver iodide; and from the solution the copper is precipitated by scrap iron, the precipitated metal being subsequently melted and refined like blister copper. The refining of copper is now carried out extensively by electrolysis. The impure copper (*e.g.* blister copper) is cast in slabs, which are suspended in a solution of copper sulphate contained in insulated, lead lined, wooden vessels. The slabs are connected to the positive pole of a dynamo, while the negative pole is connected to a thin sheet of pure copper, also suspended in the copper sulphate solution at a short distance from the slab. A current of small density and low voltage is used, and pure copper is deposited on the thin plate or Cathode. The impurities are deposited as a mud at the positive pole, and from the mud gold is recovered in many cases

Copper (*Min.*) This element occurs in the native state in films in some sandstones and in groups of octahedra. It sometimes contains small traces of silver or bismuth. Found in Cornwall, Devonshire, Wicklow, Siberia, Burra-Burra in Australia, and in large quantities at Lake Superior. A great number of minerals contain copper in combination; among the more important are Copper Pyrites, Malachite, Azurite, Cuprite, Tetrahedrite, Melaconite, Bournonite, Tenorite, Dioptase, Chrysocolla, Brochantite, Chalcanthite, Chalcocite, Erubescite, and Stannite.

Copperas (*Min.*) A naturally occurring hydrous sulphate of iron, $FeSO_4 . 7H_2O$. Iron = 25, sulphuric acid = 29, water = 45 per cent.. Also called MELANTERITE. In monosymmetric crystals, green, yellow, or white. More often in encrusting masses or as an efflorescence on pyrites, from the decomposition of which it results. Ohio and Goslar in the Harz, etc. The name Copperas is often applied in commerce to ordinary sulphate of iron.

Copper Bit *or* **Soldering Iron.** A pointed copper tool which is heated and used to melt the solder in making a joint.

Copper Compounds. Copper forms two series of compounds known as the cuprous and cupric compounds. CUPROUS OXIDE, Cu_2O: A red powder used in making ruby glass. It is made by heating a solution of copper sulphate containing excess of caustic soda and some tartaric acid with glucose (*see* Fehling's solution). CUPROUS CHLORIDE, Cu_2Cl_2: A white crystalline solid insoluble in water, soluble in hydrochloric acid, also in ammonia. It is made by dissolving cupric oxide in excess of strong hydrochloric acid, and boiling the solution with copper: when the liquid is nearly colourless it is poured into a large quantity of water. CUPRIC OXIDE, CuO: A black powder; hygroscopic; insoluble in water, but soluble in acids forming cupric salts. It is made by heating the metal in air (*e.g.* scale on a copper kettle) and by heating the nitrate. It is used in colouring glass green, and in organic analysis, because when heated with an organic compound it converts the carbon to carbon dioxide and the hydrogen to water. CUPRIC SULPHATE, $CuSO_4$: A white solid which readily absorbs water, becoming blue and forming BLUE VITRIOL, $CuSO_45H_2O$; it is made by heating the latter compound, and is used to detect the presence of water in so-called absolute alcohol. Crystallised copper sulphate, $CuSO_45H_2O$ (blue vitriol), is obtained from solution of copper sulphate in water by allowing it to crystallise. This solution may be prepared by dissolving the oxide in dilute sulphuric acid, or by heating the metal with concentrated sulphuric acid, adding water when cool, and filtering. On the large scale copper pyrites ($CuFeS_2$) is heated in air in such a way as to form copper sulphate and ferric oxide the product is extracted with water and carefully crystallised. It is used in electrotyping, in the Daniell's cell, in dyeing and calico printing, in preserving grain from "smut," and in colouring bottled peas green. Copper and copper compounds, when heated in the non-luminous gas flame, impart to it a characteristic green or blue colour. Zinc, iron, and magnesium throw out copper from solutions of its salts, an equivalent of the metal taking its place.

Copper Drift (*Eng.*) A piece of copper with a flexible handle, which is placed on finished metal work when it is struck with a hammer, in order to prevent injury to the surface.

Copper Glance (*Min.*) A cuprous sulphide, Cu_2S. Copper = 79·8, sulphur = 20·2 per cent. Also called REDRUTHITE and VITREOUS COPPER ORE. In twinned crystals of the rhombic system; also massive. Lead colour or with a greenish tarnish. It is a valuable ore, on account of its high percentage of copper. From Cornwall, Devon, Siberia, Saxony, Thuringia, North and South America, etc.

Copper Losses (*Elect. Eng.*) The waste of energy through the resistance of copper circuits in electric plant. The energy is dissipated in the form of heat.

Copper Nickel (*Min.*) A synonym for KUPFERNICKEL (*q.v.*)

Copper Pipe (*Eng.*) Extensively used for the steam pipes of large engines, etc. It can expand and contract during changes of temperature without tearing or cracking.

Copperplate. A polished plate of copper with bevelled edges, upon which an engraving is executed. *See* ENGRAVING AND ETCHING.

Copper Pyrites (*Min.*) A sulphide of iron and copper, $Cu_2S.Fe_2S_3$. Copper = 32 to 34, iron = 29 to 31, sulphur = 34 to 36 per cent. Also called CHALCOPYRITE. The commonest form of crystal is a twin of tetragonal tetrahedra. Also massive. Colour, brassy yellow, often with a darker tarnish. Very brittle, softer than iron pyrites, which it externally resembles. The chief ore of copper. Cornwall, Cumberland, Devon, Sweden, the Harz, etc.

Copper Uranite (*Min.*) A hydrous phosphate of copper and uranium, $(CuO.2U_2O_3)P_2O_5.8H_2O$. Uranic oxide = 59 to 61, phosphoric acid = 14 to 16, oxide of copper = 8·5 to 9, water = 14 to 15 per cent. Also called Torbernite, Chalcolite, and Uranmica. Occurs in implanted tabular tetragonal prisms of an emerald green colour. Cornwall, Devon, Saxony, and Bohemia.

Copping Rail (*Cotton Spinning*). An attachment on the mule which is connected to the faller wire for determining the chase or building up of the cylindrical body of a COP (*q.v.*)

Copra. The dried kernels of the cocoanut palm, *Cocos nucifera* (*Palmæ*), imported into this country. Under pressure, copra yields cocoanut oil, used in the manufacture of candles.

Coprolite (*Geol.*) A term correctly applied only to the fossil remains of the droppings of fish. Such exuviæ generally contain more or less of phosphatic matter, which is of great value, if obtained in sufficient quantities, for artificial manures. As a consequence, coprolites have been much in request for that purpose, and when other substances which afford the desired phosphatic matter have been met with, the term coprolite has been applied commercially to these, quite irrespective of their origin.

Copy (*Art*). The reproduction of an original picture or work of art. When an artist copies his own production it is termed a REPLICA.

—— (*Typog.*) Manuscript, typewritten, or printed matter handed to a compositor to be set in type.

Copying (*Photo.*) Effected either by making an ordinary negative with the camera or by some form of contact printing. The latter is very easily applied to tracings, and is generally carried out by some form of BLUE PROCESS (*q.v.*)

Copying Machine (*Eng.*) A machine for the production of a large number of similar objects by a tool, guided in a suitable manner by an automatic device.

Copyright (*Literary and Artistic*). Copyright is "personal" property, and may be defined as the sole right to produce, after publication, copies of a book, article, lecture, play, musical composition, painting, drawing, print, photograph, or a piece of sculpture. "Publication," in most of these instances, consists of tendering a work for sale publicly; in the case of a piece of sculpture it is effected by the exhibition of the work. With respect to lectures and plays, a dual right exists: (1) publishing, (2) delivering or performing. Before publication the author may restrain anyone else from publishing his work by an action at common law. The copyright of a work first published in the United Kingdom extends to all parts of the British dominions, but is subject in certain details to the local laws. In the United Kingdom, COPYRIGHT IN BOOKS lasts for forty-two years from the date of publication, or, in the event of the author dying, for the period covering his life, plus a period of seven years, should the two periods not exceed forty-two years. As regards POSTHUMOUS BOOKS, copyright dates from publication. The copyright of articles appearing in magazines and periodicals, unless otherwise stipulated, vests for a period of twenty-eight years in the editor or proprietor engaging and paying the writers of the articles; but such articles may not be published separately. In the case of PAINTINGS, DRAWINGS, and PHOTOGRAPHS, the right lasts for the life of the author, plus a period of seven years; and in the case of PRINTS the period is twenty-eight years. For SCULPTURE the period is fourteen years, plus a further similar period if the author be living at the end of the first period. Copyright in PLAYS extends for the same period as that in books. This is also the case with MUSIC. In the UNITED STATES, copyright lasts for a period of twenty-eight years, plus a period of fourteen years on re-registration; but to secure copyright for a British book it must be published simultaneously in both countries. Those countries which are signatories to the BERNE CONVENTION OF 1887, supplemented by the ACT OF PARIS OF 1896, are bound to secure for an author, who is a subject of any one of them, the same rights as the laws of his own country afford. The following countries form this union: The British Empire, Belgium, Germany, France, Hayti, Italy, Japan, Luxemburg, Monaco, Norway, Spain, Switzerland, and Tunis. Austria and Hungary have a separate convention with Great Britain.

Coquerelles (*Her.*) A French heraldic charge. Three filberts in their husks, conjoined.

Coral. A term generally applied to the hard and usually calcareous substance secreted from sea-water by the action of the coral animals, which belong to the Coëlentera. A great variety of substances have been thus formed, amongst which may be mentioned the PRECIOUS CORAL, the ORGAN PIPE CORAL, innumerable forms of coral structures which go to form coral reefs, and many other structures.

Corallian (*Geol.*) A subdivision of the Oolitic or Jurassic rocks, so called because the remains of the hard parts of various extinct forms of Coëlenterate animals are met with in the rocks on this horizon in the part of England where the rock first received the attention of geologists.

Coralline Crag (*Geol.*) *See* CRAG.

Coralline Oolite (*Geol.*) Another name for CORALLIAN (*q.v.*)

Corbel (*Architect., Build., etc.*) A projection from a wall to support a load.

Corbelling (*Build.*) Courses of bricks oversailing each other; also the supporting of some part of a building by means of corbels.

Corbel Table (*Architect.*) A series of corbels supporting an overhanging parapet; used in Norman and Early English work. In castles and fortifications the parapet and corbels were so arranged that missiles could be thrown from behind the parapet through openings between the corbels. These openings are known as MACHICOLATIONS.

Corbie Step Gable (*Architect.*) A gable formed with a series of steps. It is also known as a Crow-step Gable.

Cordite. *See* EXPLOSIVES.

Cordon (*Her.*) Used in French heraldry. A cord with tassels surrounding the shield of an ecclesiastic.

Cordovan (*Leather*). Cordovan leather is prepared from the skins of goats, formerly from horse hides. It is used in bookbinding and for boots and shoes.

Corduroy (*Cotton Weaving*). Literally king's cord. A form of weft pile weaving for heavy cloths, suitable for men's wear, which gives a rib longitudinally in the cloth. After weaving, it is cut, sheared, and finished. Often dyed.

Core (*Build.*) (1) The filling between a relieving arch (*q.v.*) and the wood lintel. (2) The mortar projecting from the joints inside a flue. (3) Broken stone, bricks, and other building materials used in filling up hollows in the ground, etc.

—— (*Carp., etc.*) The iron bar used to strengthen a wreathed handrail, etc.

—— (*Foundry*). A mass of sand or loam formed in the shape of a cavity, which has to be produced in a casting. The core is either struck (*see* CORE BAR) or produced in a core box (*q.v.*), and is fixed into the recesses in the mould produced by core prints (*q.v.*) When the casting is complete the core is extracted from the cavity in the metal by being broken up and removed piecemeal.

Core Bar (*Foundry*). An iron bar round which a cylindrical core is formed. For large cores of circular section no core box is used, but the bar is coated with foundry sand and loam, and "struck" to shape by rotating it against the edge of a suitably formed board, called a CORE BOARD or LOAM BOARD.

Core Box (*Pattern Making*). A wooden structure containing a cavity (similar to one required in a casting) in which the core is formed by ramming in core sand (*q.v.*) The box can be taken to pieces and the core removed without injury.

Cored Hole (*Eng., etc.*) Cast holes (*q.v.*)

Core Discs (*Elect. Eng.*) Discs of soft iron from which the hollow cylinder forming the core of an armature is built up.

Core Oven (*Foundry*). An oven for drying cores before placing in the mould.

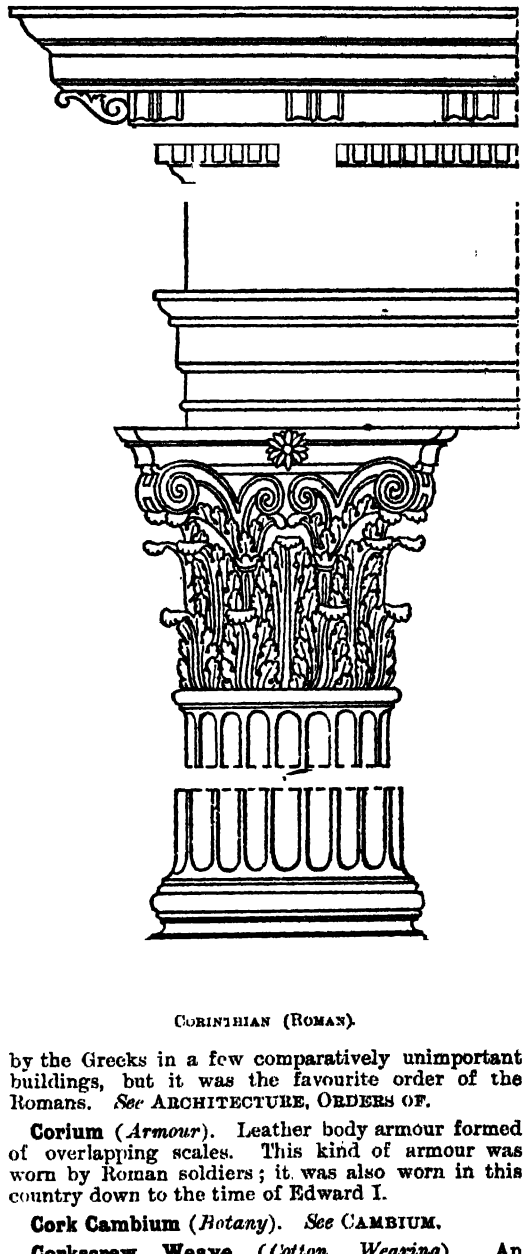
Core Plates (*Foundry*). Thin disc-shaped castings which are fixed on a core-bar in order to serve as a support for large cores. They are broken up when the removal of the core has to be effected.

Core Prints (*Pattern Making, etc.*) Projections on a pattern which form recesses in the mould into which the ends of a core (*q.v.*) are fitted. The length of the core is adjusted to equal the combined length of the hole in the casting, together with the two prints; *i.e.* a core for a hole 9 in. long, if each print were $1\frac{1}{2}$ in., would be 12 in.

Core Sand (*Foundry*). A mixture of sand with some substance to render it porous and to enable it to harden on drying.

Corf (*Met. and Mining*). A shallow basket used for handling minerals in mines. In some districts (chiefly South Yorkshire and Staffordshire) applied to a colliery "tub" (*q.v.*) and spelled CORVE.

Corinthian Order (*Architect.*) The lightest and most ornate of the classic orders. It was only used



CORINTHIAN (ROMAN).

by the Greeks in a few comparatively unimportant buildings, but it was the favourite order of the Romans. *See* ARCHITECTURE, ORDERS OF.

Corium (*Armour*). Leather body armour formed of overlapping scales. This kind of armour was worn by Roman soldiers; it was also worn in this country down to the time of Edward I.

Cork Cambium (*Botany*). *See* CAMBIUM.

Corkscrew Weave (*Cotton Weaving*). An elongated twill, travelling at a greater angle than an ordinary twill.

Corliss Engine (*Eng.*) An engine fitted with Corliss gear (*q.v.*) instead of a slide valve of the ordinary type.

Corliss Gear and Valves (*Eng.*) A form of valve gear used in many large stationary engines. Two valves are placed at each end of the cylinder. Each valve is usually a segment of a circle, and uncovers its port or opening by revolving when acted upon by a series of levers driven from the engine; disc valves and double-beat valves are also used. One valve at each end is an exhaust valve, and opens fully and practically instantaneously, thereby allowing a free escape of steam. When the exhaustion is completed the valves are closed instantly by some form of spring. The remaining valves admit the steam, and the rate at which they open is controlled by the governor. These arrangements secure great regularity and economy in the action of the engine.

Corm (*Botany*). An underground bud whose disc (stem) is much swollen with reserve material. The scale leaves are thin and sheathing. It is often mistaken for a root.

Cornbrash (*Geol.*) One of the subdivisions of the Oolites, which, in the district where it is typically developed, consists very largely of broken and comminuted fragments of shells and other calcareous matter.

Cornea (*Zoology*). The transparent portion of the sclerotic (*q.v.*) coat of the eye.

Corner Cramps (*Join.*) Cramps for drawing up the corners of picture frames, etc.

Corners (*Bind.*) (1) The material covering the corners of "half-bound" books. (2) The triangular tools used in gold or blind tooling.

Cornet. *See* MUSICAL INSTRUMENTS, WIND (BRASS).

Cornice (*Architect.*) A projecting moulding crowning the feature to which it is applied. The cornice of an order is the subdivision of the entablature above the frieze. *See* ENTABLATURE *and* ARCHITECTURE, ORDERS OF.

Cornish Boiler. *See* BOILERS.

Cornish Engine. A large type of beam engine commonly used for pumping. *See also* STEAM ENGINE.

Cornish Granite. *See* BUILDING STONES.

Corn Oil. A product of Indian corn or maize (*Zea mais*) which is extensively grown in the United States, and there eaten as a vegetable. The oil is clear yellow, and is used to a limited extent in paint manufacture. It will not, however, dry unless a liberal amount of driers is added.

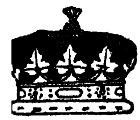
Cornucopia (*Art*). An ornament in the form of a wreathed horn overflowing with fruit and flowers. Symbolical of peace and prosperity, and generally an attribute of figures emblematical of plenty, liberality, etc.

Corona (*Architect.*) The lower part of the projecting portion of a Greek, Roman, or Renaissance cornice. It consists of a vertical face and a soffit (*q.v.*) The latter is recessed upwards so as to form a drip. *See* CORNICE, ENTABLATURE, COLUMN, BED MOULD, *etc.*

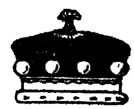
Coronæ (*Meteorol.*) Coloured rings seen round the moon (or more rarely, the sun) when viewed through a mist or thin cloud. They are due to DIFFRACTION (*q.v.*)

Coronet. An inferior crown worn by princes and the nobility, and denoting a dignity below that of the sovereign. It varies in form according to rank. That of the Prince of Wales bears on the edge four crosses "pattée" between the same number of fleurs-de-lis, and from two opposite crosses there rises an arch, surmounted by an orb and a cross. The coronet of a duke bears strawberry leaves; that of a marquis strawberry leaves alternately with pearls; that of an earl has the pearls raised above the leaves; that of a viscount is surrounded by pearls; that of a baron has six pearls only.

PRINCE OF WALES' CORONET.



DUKE'S CORONET.



BARON'S CORONET.

—— (*Her.*) The ensign of princely and noble rank.

Corozo Nut. The seed of a South American tree, *Phytelephas macrocarpa*, allied to the palms. The hardened albumen of the nut furnishes VEGETABLE IVORY.

Corpuscle (*Biology*). The solid bodies suspended in the blood. There are two kinds: (1) RED CORPUSCLES are flat discs, varying in size and structure according to the animal in which they occur. They are very numerous; in man there are about 5,000,000 per cubic millimetre. (2) WHITE CORPUSCLES or LEUCOCYTES are true animal cells, resembling the organism Amœba. Their number is about $\frac{1}{500}$ that of the red corpuscles. *See also* BLOOD *and* HÆMOGLOBIN.

—— (*Elect.*) An ELECTRON (*q.v.*)

Corpuscular Theory of Light. A theory (held by Newton) that light was due to particles emitted by luminous bodies; also known as the Emission Theory. It is now replaced by the Wave or Undulatory Theory. Many of the characteristics of Newton's theory are retained, however, if it is remembered that "the things emitted are Faraday Tubes" (*q.v.*) instead of material particles.—J. J. THOMSON.

Corrections (*Typog.*) Emendations made on a proof (printed sheet) before it is finally printed off. They should be made on the margin of the sheet and against the line where the faults occur. *See* PROOF CORRECTIONS.

Corrector of the Press (*Typog.*) A proof reader.

Corrosion (*Eng.*) Chemical action which causes destruction of the surface of a metal. Usually it is by oxidation. To diminish corrosion, paint, oil, and other substances are employed, or iron may be galvanised (*q.v.*) or treated by some process such as that of Barff. No process has yet been found which can prevent corrosion completely.

Corrosive Sublimate (*Chem.*) A common name for mercuric chloride. *See* MERCURY COMPOUNDS.

Corrugated Furnace Tubes (*Eng.*) Tubes with corrugations running right round the circumference. They are often used, as they present an increased heating surface, and also cause less strain in the main shell of the boiler, when they expand or contract, than straight tubes.

Corselet (*Armour*). A cuirass or piece of armour for covering the body, usually worn by pikemen, who were sometimes styled CORSELETS. Attached to the corselet in the case of footmen was armour for the thighs, called TASSETS.

Corsite (*Geol.*) A variety of diorite which shows a remarkable orbicular structure, due to an unusual disposition of its component minerals during its consolidation. It is sometimes called Napoleonite or Orbicular Diorite.

Cortile (*Architect.*) An interior court in a dwelling house.

Corundum (*Min.*) Native sesqui-oxide of aluminium, Al_2O_3. Aluminium = 53·4, oxygen = 46·6 per cent. It crystallises in hexagonal pyramids, and also occurs massive. Colour very varied. The massive form yields EMERY (*q.v.*) The finer coloured varieties yield many of the gems. *See* RUBY, SAPPHIRE, *and* AMETHYST (ORIENTAL). Found in East Indies, Piedmont, St. Gothard, Auvergne, New York, Burmah, etc. *Cf.* Carborundum.

Cos, Cosine. *See* TRIGONOMETRICAL RATIOS.

Cosec, Cosecant. *See* TRIGONOMETRICAL RATIOS.

Cost (*Her.*) *See* COTISE.

Costing (*Manufactures*). The determination of the cost of producing or distributing any given work.

Cost Sheet (*Manufactures*). A statement of the cost of production of given work. It should show the cost of labour, materials, general charges, depreciation of tools, etc., and each of these items may be further subdivided with advantage where several varieties of labour and materials are used in each piece of work.

Cot, Cotangent. *See* TRIGONOMETRICAL RATIOS.

Cothurnus (*Archæol.*) A Grecian hunting-boot laced up in front and reaching to the middle of the leg; also worn by tragic actors. *See* BUSKIN.

Cotise, Cottise (*Her.*) A diminutive of the bend, being one-half of the bendlet and one-fourth of the bend. When borne alone, it is termed a "Cost," but when borne in pairs, "Cotises."

Cotised (*Her.*) When an ordinary, such as a bend or fess, is bordered on both sides by a cotise, barrulet, etc.

Cottar (*Eng.*) A tapered pin or wedge used for tightening up and fixing parts of machinery.

Cottar Way (*Eng.*) A tapered slot through which a cottar passes. *See* COTTAR.

Cotton. *Gossypium* (various species; order, *Malvaceæ*). Three species of this plant yield the well-known material cotton, which is formed from the fibres covering the seeds. The seeds are used also in making cotton seed oil (*q.v.*) and oil cake. When woven into a fabric, cotton is durable, non-shrinkable, does not absorb moisture, and is a good conductor of heat. These features point to the conclusion that it should not be worn next the skin.

Cotton Manufacture. This industry may be divided into two distinct branches, *viz.* (1) Spinning; (2) Weaving. There are a few firms in England who carry on both industries, but it is the exception rather than the rule. On the Continent and in America the two are usually worked together under separate inside management. A firm who take both branches would be styled cotton spinners and manufacturers. It is the province of the spinner to convert by mechanical methods the fine short cotton fibres obtained from the cotton tree into a continuous uniformly twisted thread of unlimited length, the coarseness or fineness of which may be varied to suit the requirements of the trade. The manufacturer, in his turn, has to prepare the spun yarn so that when a number of threads are run together in parallel order in a convenient form in the loom woven cloth is produced. COTTON SPINNING: The primitive method of spinning was by means of the distaff (*q.v.*) and spindle, which gave place later to the domestic hand spinning wheel. In the year 1530 this was superseded for special purposes by the Saxony spinning wheel. This wheel both put the twist into the thread and wound it on a bobbin by means of a flyer. A very good spinner would be able to work a wheel containing two spinning spindles. An average number of spindles which at the present day may be attended to by a mule spinner and his two assistants is about two thousand. According to Dr. Ure, the earliest period that cotton is known to have been used in England as a textile staple was in the latter part of the fifteenth century. This industry, together with weaving, was carried on as a domestic occupation until the invention of Robert Kay's fly shuttle on the hand loom gave an impetus to the spinning industry, and was the means of bringing out in quick succession the inventions of Hargreaves, Arkwright, and Crompton. The advent of Arkwright's water frame, about 1769, was the means of gradually changing the whole system of domestic manufacture from the manual to the mechanical, and eventually establishing our present day factory system. The value of a cotton fibre for spinning purposes is determined by the following characteristics: length, fineness, uniformity in diameter and convolutions, cleanliness; the best and strongest spun yarns being those in which the greatest number of fibres in proportion to thickness of thread may be consolidated in a cross section. The following are the chief commercial staples of cotton used, given in order of importance and value: (1) Sea Island; (2) Egyptian; (3) Brazilian; (4) American; (5) Indian. The finest yarns are spun from Sea Island and Egyptian; the coarsest and low qualities from Indian cotton. The bulk of the cotton used for medium class yarns is American, and it is for this staple that there is the greatest demand. It may be mentioned here, that recently a cotton growing association has been formed in England among the spinners and manufacturers to experiment and eventually cultivate in some British possession a cotton fibre equal to, if not better than, the American, so that the control of the cotton market may be taken out of the range of speculators "who toil not, neither do they spin." The Germans are also adopting the same course in their African possessions. After the cotton lint or fibre is picked from the pod, it undergoes the process of "ginning" near to the cotton fields, and is then graded. It is afterwards packed by steam or hydraulic pressure in the form of an oblong bale, ready for transit to any part of the globe. In America the compressed rolled bale is very extensively used. It is in the bale form that the spinner receives it, and after being tested for weight, quality, and moisture, it undergoes the various stages of manipulation until a solid, approximately uniform, and cylindrically twisted thread is produced. The following is the order of processes that cotton would pass through in a modern English mill fitted up for spinning medium counts of yarns: (1) Bale breaker, (2) Mixing or Blending, (3) Open-

ing, (4) Scutching, (5) Carding, (6) Drawing (three heads), (7) Slubbing, (8) Intermediate slubbing, (9) Roving, (10) Spinning either by the ring frame or mule. When fine yarns of good quality are being spun it is necessary to introduce three other processes between the carder and drawing frame—*viz.* (*a*) Sliver lap machine, (*b*) Ribbon lap, (*c*) Combing; also, in many cases, an extra flyer frame, called a jack frame, would be used to follow the roving frame. Some spinners will sell the yarn for "twist" or "weft" direct from the spindle in the mule cop or ring bobbin; whilst others will have attached a reeling, warping, and doubling business. In the majority of cases, however, doubling is treated as another branch, along with gassing. When reeling and warping are attached there is a greater outlet for the sale of yarns, as, in addition to the cop and bobbin, it may be sold in the hank, balled warp, or chain lengths to suit the convenience of the manufacturer. The chief points of difference between the English and American systems of spinning may be summed up as follows: In England cotton is only carded once and drawn three times, and the majority of spinning spindles are on the mule, although a large number of rings are in use. In America they usually card the cotton twice and draw it twice, whilst their spinning machines are invariably ring frames, so that ring weft on a bobbin may be supplied direct to the weaver in addition to being used for warp. Reeling is practically unknown. A system of spinning is also in vogue, especially on the Continent, for respinning waste yarns into coarse counts, known as waste spinning. COTTON WEAVING: By weaving is meant the art of forming a cloth or fabric by the interlacing of strands or threads of various thicknesses one with another in order to form one broad sheet. Two distinct sets of threads, known as the warp and the weft, are used in the formation of the cloth. Early records point to the fact that in a simple way weaving was practised by the Egyptians, Chinese, Hindoos, and Greeks long before the art became known in England. It is said that we are indebted to the Romans for its introduction into this country, since on their invasion they commenced to weave woollen cloths for the use of their soldiers. The adoption of cotton as a textile staple was much later. *See* COTTON SPINNING. The inventions of Arkwright and Crompton in the spinning industry had the effect of giving a greater supply of yarn to the hand loom weaver than could be dealt with; hence there soon followed the invention of the power loom by Dr. Cartwright. His idea was to produce a machine that would be partially automatic in its action, and so, by enabling one person to attend to more than one loom at the same time, afford the means of dealing with the stock of yarn produced by the spinning spindles. The success of his invention revolutionised the weaving industry, and it may be said that our present day loom still retains, in the main, the chief features of Cartwright's invention. From this time onward the cotton industry continued to expand until it was found necessary to treat spinning and weaving as two separate branches of industry, as we find them to-day. The industry has also spread to such an extent on the Continent and in the United States of America—to a lesser degree in India, China, and Japan—that these countries make themselves felt as keen competitors, especially in our foreign trade. In order to produce cloth satisfactorily and economically, certain preparatory processes are necessary. These processes provide a warp beam containing warp threads in such number and length that any desired quality and width of cloth may be produced when in the loom. In present day manufacturing there are two main divisions—*viz.* (1) Grey Goods; (2) Coloured Goods. Each of these may be again split up into (*a*) Plain weaving; (*b*) Fancy weaving. A manufacturer of plain goods will produce fabrics of a simple or plain character, such as calicoes, twills, sateens, muslins, lawns, etc., known as "tappet" work. A fancy goods manufacturer will produce, in addition to the above, fabrics of a fancy weave character, comprising small figured or floral effects which require tact and skill in the arrangement of design. This necessitates the employment of more costly machinery in the form of dobbies or jacquards. The general English system of preparing grey and coloured warp threads for the loom are herewith given. GREY GOODS: The warp yarn is received in the twist cop, or ring bobbin, and undergoes the following processes: (1) Winding; (2) Beam warping; (3) Slashing and sizing; (4) Twisting or drawing in; (5) Weaving in the power loom, fitted up with either tappet, dobby, or jacquard. COLOURED GOODS: Two distinct systems of preparation are in vogue, each of which has its advantages, namely (A) Warping; (B) Yorkshire dressing. *System A:* The twist yarn is received in the grey hank state, and, after being bleached or dyed the required colours, undergoes the process of hank sizing, in addition to which the following processes are gone through: (1) Drum winding; (2) Warping; (3) Beaming or running on machine; (4) Drawing in or twisting; (5) Weaving as above. *System B:* The twist yarn, received in the form of balls or chains, is warp dyed and sized, and passed on to the dresser, who puts it through the process of Yorkshire dressing. From this stage the processes are as 4 and 5 in System A. The Scotch system of preparing coloured warps is mostly by the long chain or Scotch beaming process, which is similar to Yorkshire dressing, only that each colour is previously run on to a separate beam before all are run together on the weaver's beam in their pattern. The American system is similar to the Scotch, that is for coloured goods. The warps are made on a lease or chain warping machine, afterwards being dyed the required colours. The colours are then each run on to separate beams, only in their *unsized* condition. All the coloured ends from the beams are then run together on the weaver's beam in their correct pattern by means of the slasher sizer. Two size boxes are usually employed, one for white threads to run through, and the other for all colours. The American system for grey work is similar to the English.—H. B. H.

Cotton Blanket. *See* BLANKET.

Cotton Cords (*Eng.*) Ropes of cotton one-half to five-eighths of an inch in diameter, sometimes used for transmitting power in place of leather belts.

Cotton Covering (*Elect. Eng.*) Insulation consisting of one or more layers of fine cotton wound round wires in which high insulation is not necessary, *i.e.* where the voltage of the current in the wire is low.

Cotton Felt (*Paper Manufac.*) An endless cloth used for keeping paper in contact with heated cylinders during the operation of drying.

Cotton Gin. A machine used for separating the cotton lint from the seeds after picking from the pod. There are several kinds—the primitive Churka

gin, roller gin, saw gin. The two latter are mostly used, and of these there are several single and double acting patterns.

Cotton Seed Oil. Is obtained from the outer shells of the seeds of various kinds of the cotton tree, *Gossypium.* Until recent years these husks were deemed worthless, but now the cotton oil industry is an exceedingly large one, crushing of the seed being carried out in many places in England and abroad. The oil when expressed is of a ruby colour, and when refined pale yellow. It possesses a pleasant nutty flavour, and is very largely employed as a salad oil, for adulterating olive oil, butter, and lard, and in the manufacture of margarine. It is also used for pastry, fish frying, and in the manufacture of lubricating oils, soaps, and candles. When used as a food it is necessary to free it from stearin (*q.v.*) This is sometimes effected by merely allowing the oil to stand in storage tanks, and sometimes by chilling or by placing the oil in cylindrical bags of finely woven linen and allowing it to filter through, which it does slowly, leaving the stearin behind. Its specific gravity at 60° F. is 0·922 to 0·928.

Cotyledons (*Botany*). The temporary seed leaves of an embryo plant, functioning either as an absorbing organ or as storage places. There are two present in the seeds of dicotyledons, one in monocotyledons.

Cotyliscus (*Archæol.*) A small Greek vase with one handle, resembling the amphora in form.

Couch Roll (*Paper Manufac.*) A felt-covered roll used for squeezing out surplus water from the wet sheet of paper after it leaves a machine wire.

Coulisse, Cullis. The slides or grooves in which the side scenes run on the stage of a theatre. Applied also to a side scene itself and to the space between the side scenes.

Coulomb (*Elect.*) The quantity of electricity conveyed by a current of one ampère (*q.v.*) in one second.

Coulomb's Balance (*Elect.*) *See* TORSION BALANCE.

Coulomb's Law (*Elect.*) In electro-statics the force between two charges of electricity is proportional to their product, and inversely proportional to the square of their distance apart. In magnetism the force between two magnetic poles follows the same law.

Coumarin (*Chem.*) $C_6H_4\left\langle\begin{array}{l}^{(1)}CH : CH \\ \qquad\quad\ | \\ ^{(2)}O - CO\end{array}\right.$

A white crystalline solid with pleasant aromatic odour. Melts at 67°. Easily soluble in alcohol and hot water. Obtained by the action of acetic anhydride and sodium acetate on the aldehyde of salicylic acid. It occurs in Tonka beans, melilot, and woodruff. Used in perfumery.

Count (*Textile Manufac.*) *See* COUNTS.

Counter. (1) The curved part of a ship's stern. (2) That part of a horse that lies between the shoulders under the neck. (3) An imitation coin made of inferior metal. (4) A token.

Counterbalancing (*Eng.*) *See* BALANCING.

Counterbracing (*Eng.*) Strengthening a structure by means of tie rods running in opposite directions.

Counterchanged (*Her.*) When the field is parted per chevron or other ordinary, one half the field being metal and the other a colour, the tinctures of charges which fall upon the metal and colour are reversed.

Counter Cramp (*Carp. and Join.*) A cramp for drawing up and fixing the end-grain joints of strings (*q.v.*), counters, etc.

Counter Electromotive Force (*Elect. Eng.*) An E.M.F. in the armature of a motor while running, produced by its tendency to act as a dynamo, and thereby opposing the flow of the current which is being supplied to the motor. An ordinary continuous current motor takes less current as its speed rises, for the counter E.M.F. increases with the speed.

Counter Floor (*Carp. and Join.*) A foundation for laying a parquet floor on.

Counter Lath (*Carp., etc.*) Laths nailed across each other: similar to brandering (*q.v.*)

Countermark (*Archæol.*) The name given to impressions that are sometimes found on ancient coins and medals, and which have been effected subsequent to the first stamping of the coin. It is not certain why such marks have been made on ancient coins, but during the Peninsular War the British authorities were also in the habit of stamping Spanish dollars with a small countermark of the head of George III.

Counter Passant (*Her.*) Said of two beasts passing each other in opposite directions.

Counter Plate (*Engrav.*) Additions required to an engraving are made upon another plate and then printed off upon the original engraving. This second plate is called the counter plate.

Counterpoint (*Music*). The art of combining melodies. Contrapuntal study is divided into five species: (1) Note against note of the Canto Fermo. (2) Two notes against one of the Canto Fermo. (3) More than two notes against one of the Canto Fermo. (4) Syncopated. (5) Florid.

Counter Potent (*Her.*) One of the furs. The potents are arranged head to head, as in counter vair (*q.v.*) *See also* HERALDRY.

Counter Proof (*Engrav. and Print.*) A proof taken off another fresh-printed proof, the copy on the second proof being, of course, reversed.

Counter Shaft (*Eng.*) A subsidiary shaft driven from the main shaft, for transmitting and distributing power. It usually carries a coned pulley (*q.v.*) corresponding to a similar pulley on the machine which it drives.

Counter Sinking (*Eng., etc.*) Forming a recess at the top of a drilled hole to receive the head of a screw or rivet.

Counter Subject (*Music*). That part which accompanies the "Answer" in a fugue.

Counter Tenor (*Music*). *See* ALTO.

Counter Vair (*Her.*) One of the furs. The bells or cups are all of the same tincture, and placed base to base and point to point.

Countess Slate (*Build.*) A roofing slate 20 in. by 10 in.

Counting Glass (*Linen Manufac.*) Magnifying glasses made up in little frames having apertures of different sizes cut to standard gauges. When laid on a piece of linen, the number of threads appearing through the aperture are counted, and indicate the fineness of the cloth. These are also called "wet glasses" (*q.v.*)

Country Rock (*Mining*). The rock through which a vein runs.

Counts (*Cotton Spinning*). Refer to the diameter and weight of cotton yarns for a standard length. Single thread counts are denoted by the number of hanks of 840 yds. in 1 lb. (avoirdupois) or 7,000 grs. (Troy). Example: a 20 cotton thread = 20 hanks to 1 lb. ∴ 20 × 840 = 16,800 yds. to 1 lb. Folded-yarn counts are determined by the number of threads twisted together. Low coarse counts are denoted by yards per ounce.

—— (*Woollen Manufac.*) Applied to yarns as indicative of size or thickness and the number of yards in a given weight. Cotton counts are based on the number of hanks of 840 yds. in 1 lb.; Worsted, on the number of hanks of 560 yds. in 1 lb.; and Woollen on the number of skeins of 1 yd. in 1 dram.

Couped (*Her.*) Cut straight. When a charge, such as a head or leg of a man or beast, is cut off evenly and not erased.

Couple (*Mech.*) A system of two opposite equal parallel forces not in the same straight line. A couple can only produce a turning movement, not translation or movement from place to place.

Couple Close (*Carp.*) A roof having the lower ends of the rafters tied to prevent them from spreading.

Coupled Wheels (*Eng.*) Locomotive wheels connected by connecting or coupling rods. This ensures the distribution of the weight over two or more pairs of wheels, and increases the uniformity of running.

Couple, Electric. Any pair of substances, in contact or connected together, which can give rise to a difference of electrical potential, *e.g.* zinc coated with copper, or a plate of zinc and copper connected by a wire.

Couple Roof (*Carp.*) A roof having no tie at the lower end of the rafters. Cf. COUPLE CLOSE.

Couple, Thermo-Electric. Two metals which produce a difference of potential when heated at their junction.

Coupling (*Eng.*) (1) The appliance for connecting rolling stock on a railway. (2) In general, the connection of any two pieces of mechanism so that they operate together, *e.g.* shafts, wheels, engines, etc.

Coupling Lash *or* **Leish** (*Silk Manufac.*) The thread carrying lingoe (*q.v.*) and attached to mail, and carried from mail to necking cord, in figured harness.

Coupling of Dynamos (*Elect. Eng.*) Running two (or more) machines to supply the same circuit simultaneously.

Couplings (*Cotton Weaving*). An attachment to a Jacquard harness. It is suspended from the neck cords, and consists of sleeper cord, mail, and lingoe. One coupling is required for each separate warp thread in the width of cloth.

Course (*Build.*) (1) One layer of bricks or stones of the same height. (2) The vertical distance between two horizontal joints.

Coursed Rubble (*Build.*) Rough stones squared and built in courses varying in height.

Couteau de Chasse. A hunting knife of the sixteenth and seventeenth centuries. The sheath contained also smaller knives and other implements useful to the hunter.

Cove (*Plast., etc.*) A hollow curved moulding.

Coved Ceiling (*Plast., etc.*) A ceiling having a large hollow cornice.

Cover (*Cotton Weaving*). A term used to indicate that the warp threads are spread in the cloth width at equal distances, so as to destroy any raw or naked appearance which may arise by the threads passing in pairs or more through the splits in reed (*q.v.*)

Cover Chief (*Cost.*) A headdress resembling a nun's veil. In common use during the Middle Ages.

Covering Power of Pigments (*Dec.*) Often confused with the term "body" (*q.v.*) It refers to the extent of surface a pigment will cover, or the superficial area over which it will spread when thinned to a consistency suitable for being applied with a brush. The surface in square feet covered by 10 lb. of the following materials applied evenly to wood is, according to Hurst: Red lead, 113; white lead, 221; zinc oxide, 378; red oxide, 453; chrome yellow, 252; Brunswick green, 310; lampblack, 382; ultramarine, 462.

Cover Stones (*Build.*) Flat stones laid on the top of girders, etc., as a foundation for the wall above.

Cow Hair. Is mixed with plaster, foundry loam, etc., to ensure cohesion or porosity.

Cowls (*Hygiene*). Used for the purpose of aiding ventilation of buildings. They are fixed on outlet ventilating shafts, and are said to increase the exhausting action which the wind exerts when passing over the tops of these shafts. They prevent down-draughts, and also prevent the entrance of rain. The disadvantage of cowls is the uncertainty of their action.

Cowper Stove (*Met.*) A Regenerative Stove (*q.v.*) for heating the blast by the combustion of the furnace gases.

Cowrie, Cowry. *Cypræa moneta* (class, *Gastropoda*). A small shell found in Eastern seas and used as money in Africa and East Indies.

Cowrie Pine, Kauri Pine. *See* TIMBERS.

Cow's Milk (*Foods, Hygiene*). The quality and quantity varies with the age, breed, food, and condition of the cow. Milk is a perfect food, containing all the proximate alimentary principles—*i.e.* proteids, fats, carbohydrates, salts, etc.—necessary for the sustenance and development of a child. It is therefore of the highest importance that it should be supplied pure and unadulterated. That this is not so is well known. Water is the chief adulterant; but cane sugar, glycerine, carbonate of soda, boric acid, formalin, etc., and annatto, for colouring are also added. Milk plays a very important part in the cause and spread of many of the infectious diseases. Great care should be taken that milk is not placed where it will be liable to contamination, as it readily absorbs gases and vapours, and, moreover, affords a good breeding ground for the growth and multiplication of micro-organisms

Coypu. *Myopotamus coypu* (family, *Octodontidæ*). A South American rodent of beaver-like habit. The under-fur, which is imported in large quantities, is known as PUTRIA or RACOONDA.

Cr. (*Chem.*) Symbol for CHROMIUM (*q.v.*)

Crab. A windlass or winding mechanism similar to that of a crane. It includes a barrel on which the chain or rope is wound, and a winch or crank handle whose shaft is usually connected to the barrel by toothed gearing. The term is also applied to a similar machine driven by power.

Crabbing (*Woollen Manufac.*) A compound process of boiling and blowing pieces of cloth with steam while lightly wound on a perforated roller, to prevent subsequent wrinkling of the cloth, etc.

Cracking of Varnish (*Dec.*) This fault in a varnished surface is sometimes caused by applying the varnish over a coat of paint that has not dried hard; or by applying a coat of hard varnish over an elastic varnish. If the fault arise from the varnish itself, it is usually due to an excess of drying material being used in the manufacture.

Crackle (*Pot.*) A species of pottery, the glazed surface of which is crazed or cracked in the firing process. Japanese pottery of this description is highly valued.

Cracowes (*Cost.*) Shoes with long pointed toes. First worn in the fourteenth century at Cracow in Poland. In England it was necessary to pass a law regulating their length.

Cradle (*Dec.*) A movable scaffold consisting of a platform railed in on two sides and suspended by ropes by which it is raised or lowered. Used by painters and builders when ladders cannot be conveniently employed. The loose ends of the ropes are held by men on the ground, but in some patented patterns the cradle may be operated by those who are in it.

—— (*Eng.*) A name often used in mechanism for a support or system of supports, especially for those carrying an object which can be easily lifted out and replaced.

—— (*Lace Manufac.*) In a lace machine, a curve concentric with the centre of an oscillating movement, and forming a "bed," which gives support and prevents or minimises vibration.

—— (*Mining.*) A rocking frame for washing ores.

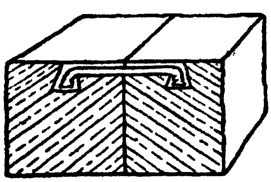
Cradling (*Carp. and Join.*) (1) The rough bracketing round a girder to which the lathing is nailed. (2) An arrangement for glueing up treads and risers (*q.v.*) in making a staircase.

Crag (*Geol.*) A name for a geological formation (as distinguished from a geographical feature). This term is applied to certain shelly sands and gravels which were formed during Pleiocene times, chiefly in East Anglia. Thus there is the CORALLINE CRAG (so called from the abundance of polyzoa, not of corals, which it contains), the RED CRAG, NORWICH CRAG, etc.

Cragleith Stone. *See* BUILDING STONES.

Cramming (*Plumb.*) To plug up a pipe with bread, etc., while a joint is being made.

Cramp (*Build.*) A bar of iron with the ends bent at right angles; used for fixing stones together.



CRAMP.

—— (*Join., etc.*) A tool made in a great variety of forms, by means of which sustained pressure can be applied to a piece of work; *e.g.* cramps are used to hold glued joints together while the glue is setting. The pressure is usually applied by means of a screw.

Cramponné (*Her.*) A charge is cramponné when its termination is in the form of a cramp: an iron used in building, having each end bent. *See* CRAMP.

Crampoon (*Build.*) A clutch for holding blocks of stone or balks of timber when they are required to be raised by means of a crane.

Crancelin (*Her.*) A coronet extended in bend; also blazoned a bend treflée vert. It is borne in the arms of Saxony.

Crane. A crane is a piece of machinery used for raising heavy weights to some distance above the level of the ground. In the simplest form the crane consists of a roller or drum, round which a chain is wound, and which is turned either by hand or by power. The chain passes over a pulley wheel, fixed on the end of a long beam called the jib. The jib is usually hinged at its lower end to the frame of the machine, from which it projects at an angle, and this angle can in many cases be altered. In order to keep the jib at its proper angle, either tie rods or chains are fixed to it. These tie rods or chains are brought down and fixed to some part of the frame or baseplate. If the chains are so arranged that they can be lengthened or shortened, the angle of the jib can be easily adjusted. A crane whose jib can be adjusted in this way is termed a DERRICK. The whole frame is usually carried on a vertical axis or crane-post, so that the crane can turn through a considerable angle or even make a complete revolution. This pivot is fixed in the base or foundation in the case of stationary cranes, and in the case of portable cranes to a very strong carriage, which runs on rails. A crane of this type usually has the following separate motions: (1) The ordinary hauling action of the crane, by which the load is raised or lowered. (2) A derricking motion, by which the jib can be fixed at any convenient angle, thus altering the area over which the crane can work, and enabling the load to be moved or "swung" nearer to or farther from the crane after it is raised. (3) A rotary motion about the vertical axis of the crane, enabling the load to be swung round through any part of a circle. (4) A travelling motion whereby the crane can run along its line of rails. All these motions can be obtained from the action of the engine which drives the crane, and which is mounted on the framework of the crane itself. To counteract the tendency of such a crane to overturn, some heavy weight is fixed on part of the frame opposite to the point at which the jib is fixed. This weight may be any heavy mass of convenient size, or in the case of steam cranes it may consist of the engine and boiler themselves. These arrangements constitute what is called a BALANCE CRANE. In many cases the power of the crane is supplied by a hydraulic engine or an electric motor; the former is chiefly suited to the working of stationary cranes. The jib is sometimes dispensed with, and the hauling mechanism is then fixed on beams overhead, so that it can run along in either of two given directions. Such a crane is called a TRAVELLER, or TRAVELLING CRANE, and is used in engineering shops. Large girders are fixed along two longer walls of the shop, and a frame consisting of a couple of girders equal to the distance between these two longer girders can be moved along the latter on wheels. A crab or hauling mechanism is then mounted on two shorter girders, so that it can run along them when required. The power is very commonly transmitted to a traveller from a fixed engine or motor placed on the floor of the shop, but the most convenient arrangement is to have an electric motor contained in the crane itself, as the current can easily be conveyed to it. For harbour works, etc., some form of traveller is frequently used, running on rails, as a jib crane is

scarcely strong enough to deal with the enormous weights which have to be moved. A GOLIATH CRANE is a traveller in which the cross girders are mounted on standards which are provided with wheels at their bases, so that the whole structure can run along on rails laid down for the purpose. A HERCULES CRANE is a travelling crane with a horizontal jib. An ACCIDENT CRANE is a portable crane mounted on a railway truck.

Crane Post (*Eng.*) The vertical pillar in a crane. To the top are attached the tie rods supporting the jib; the bottom is fixed to the base plate of the crane.

Crank (*Eng.*) A lever keyed at right angles to a shaft or made solid with it, by means of which the shaft is turned, or imparts motion. When the shaft is of small diameter, it is often bent, in order to form the crank, as in the case of the crank shaft of a foot lathe. There are several forms, single-, double-, disc-cranks, etc.

Crank Axle (*Cycles*). The spindle to which the two cranks and the driving chain wheel are fastened; it runs in ball bearings in the bottom bracket. *See also* CYCLES.

Cranking (*Eng.*) (1) Bending in some special manner. (2) The curving or hollowing out of a cutting tool behind the cutting point or edge in order to allow a certain amount of spring in the tool.

Crank Pin (*Eng.*) The cylindrical stud or pin of a crank, to which the connecting rod is attached.

Crape. A material of light texture, with a crimped surface, made of handspun silk yarn in the natural state. On adding to the texture a quantity of gummy matter in finishing, the threads "creep" or crimp. Crapes are also made of worsted yarns, the effect being obtained by passing the pieces between engraved rollers.

Crash (*Dec.*) *See* CANVAS WALL COVERINGS.

Crater (*Geol.*) A term generally restricted to the funnel-shaped cavity which forms the mouth, or uppermost part, of a volcanic vent.

—— (*Pot.*) A large vase or cup with two handles, and having a wide, open mouth. It was used by the Greeks and Romans for mixing wine and water.

Crawling (*Dec.*) A defect in varnished work which sometimes takes place when there is a sudden change in temperature while the varnish is drying, particularly when the coat of varnish is too thick. The defect cannot be remedied, and the only cure is to remove the varnish and do the work again.

Crayon (*Art*). A kind of pencil for drawing, made of chalk mixed with other materials, black, white, or coloured.

Craze (*Pot.*) When the glaze on the surface of pottery is cracked it is said to be CRAZED. Caused by accident in the process of firing.

Creak (*Met.*) The cracking sound made by metallic tin when bent. Sometimes termed CRY. The sound is due to the rubbing together of the crystalline particles of the metal.

Cream Laid. Writing paper with a ribbed surface, of a cream colour.

Cream of Tartar (*Chem.*) A common name for acid potassium tartrate. *See* TARTRATES.

Cream Wove. Hand-made writing paper, having a smooth surface and of a cream colour.

Creasing Course (*Build.*) A course of tiles (near the top of a wall) projecting on each side to throw off the rain, and to prevent the water from soaking down the wall: a damp-proof course at the top of a wall.

Creatine, Methyl Guanidine Acetic Acid,

$$HN : C \begin{cases} NH_2 \\ N\,.\,CH_3\,.\,CH_2\,.\,COOH \end{cases} .$$

White prisms containing 1 molecule H_2O: soluble in water. It occurs in muscle, especially in the juice. Can be made artificially from sarcosine (methyl glycocoll) and cyanamide, $CN\,.\,NH_2$. It is present in all meat extracts. Acids, on digestion, convert it into creatinine, the same change occurring on evaporating its solution. Baryta water changes it to urea and sarcosine.

Creatinine (*Chem.*), $HN : C \begin{cases} NH\text{———} \\ N\,.\,CH_3\,.\,CH_2\,.\,CO \end{cases} .$

White prisms: soluble in water: strong base giving salts with acids. Forms a highly characteristic compound with zinc chloride $(C_4H_7N_3O)_2ZnCl_2$, which is very sparingly soluble in water and whose formation serves as a means of separating creatinine from its solutions, *e.g.* from urine, of which it is a normal constituent. Creatinine reduces Fehling's solution (*q.v.*), and normal urine owes its slight reducing power to this substance. It is formed from creatine (*q.v.*), and is reconverted into this on boiling with alkalis.

Credentia *or* **Credence.** A kind of small sideboard with one or more shelves. In churches the credence table is used to hold the sacred vessels before they are placed upon the altar.

Creel (*Cotton Spinning*). A stand to hold a number of bobbins either on a flyer frame, ring frame, mule or warping machine. There are three kinds: (1) straight, (2) circular, (3), V-shaped.

Creep (*Mining*). The movement or bulging of the floor of a mine through the pressure of the rocks around.

Creeping (*Eng., etc.*) The slight slip which occurs between a belt and the wheel or drum over which it runs. Also a general term for a slow movement of one part of a structure relative to another part which is in contact with it.

—— (*Chem., etc.*) The tendency of certain solutions of salts to ascend the sides of their containing vessels, and leave a solid deposit (*e.g.* sal-ammoniac solution).

Creeping of Tyres (*Cycles, Motors*). A tendency for a tyre to rotate relatively to the rim. Creeping not only loosens the tyre, but also tends to produce leakage through the strain set up at the valve.

Cremation (*Hygiene*). The cremation of human remains is regulated by the Cremation Act, 1902. Burial authorities under this Act are empowered to provide and maintain CREMATORIA, which must not be constructed within a specified distance of a dwelling house or public highway, and are subjected to regulations prescribed by the Secretary of State. This hygienic disposal of human remains is in operation at Woking, Liverpool, Manchester, Hendon, etc.

Cremnitz White *or* **Vienna White** (*Paint.*) A pigment composed of pure white lead.

Cremona *or* **Cremonese.** A name given to violins made at Cremona, a town in Lombardy, in the seventeenth century by the Amati family, and in the early eighteenth century by Stradivarius. These instruments have never been excelled, and command very high prices.

Creosote (*Chem.*) A liquid obtained from either wood tar or coal tar. That from wood tar is derived from the fraction, heavier than water, obtained on distilling the tar. This is treated with alkali, and the solution produced is separated and precipitated with acid, then distilled. The fraction which distils at 200° to 220° is creosote. It is a mixture of phenol, cresol, and the methyl ethers dihydric and trihydric phenols with other substances. Coal tar creosote is that fraction of coal tar which distils between 230° and 270°. It contains phenol, cresol, napthalene, anthracene, and many other substances. Wood creosote is colourless: coal creosote is greenish and fluorescent. Creosote is used in preserving timber and as a disinfectant. Creosote is not soluble in water, and to make it so for use as a disinfectant (*e.g.* Jeyes'), resin and caustic soda are added to it.

Creosoting (*Eng.*, *etc.*) The impregnation of timber by first drying in a vacuum and then soaking in CREOSOTE (*q.v.*) under pressure. The durability is very greatly increased by this process, especially in the case of timber which is to be exposed to the open air or to be partly underground (*e.g.* railway sleepers).

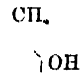
Crepon. A dress fabric, the surface of which is cockled, composed of a shrinkable and an unshrinkable yarn.

Crequier (*Her.*) A French charge, representing a chandelier of seven branches.

Crescendo (*Music*). Increasing in loudness. Abbreviation, *Cres.*, or $<$.

Crescent (*Her.*) A charge in the form of a half moon. Also used as a mark of difference on a label, to distinguish the second son.

Cresols (*Chem.*), $C_6H_4\left\langle\begin{matrix}CH_3\\OH\end{matrix}\right.$. There are three of



these compounds, *viz.* ORTHOCRESOL,

METACRESOL, 
; PARACRESOL, 

. The first melts at 31°, the second at 4°, and the third at 36°. O-cresol gives a blue colour with ferric chloride. They all occur in wood tar and coal tar. They are obtained from the corresponding toluidines (*q.v.*) by means of the diazo reaction. Like phenol they have a disagreeable smell, are antiseptics, but less poisonous than phenol. They are not oxidised by chromic acid. P-cresol is a product of the putrefaction of albumin.

Crest (*Her.*) An adjunct to the shield, represented on a wreath, coronet, or chapeau, and placed above the helmet in an achievement. In ancient times worn on the helmet as a distinctive mark.

Cresting (*Architect.*) An enriched finishing surmounting any feature of a building. It is also known as BRATTISHING. A crest much used in Perpendicular Gothic work is known as the TUDOR FLOWER (*q.v.*)

Cresylic Acid (*Chem.*) A name given to the uncrystallisable liquid obtained in the manufacture of phenol: it is chiefly a mixture of the cresols.

Cretaceous System (*Geol.*) The uppermost member of the Secondary Rocks. It is so called because a conspicuous member of the system is the Chalk (Latin, *creta*). The system includes the Upper Greensand and the Gault, which, with the Chalk, form the Upper Cretaceous rocks of those geologists who regard the Lower Greensand as an inferior member of the Cretaceous System.

Crib (*Mining*). A hollow cage-like structure of timbering. It may be left empty, as when it lines any cavity, or be filled with rock, etc., to form a support for the roof or other part of the workings.

Cribwork (*Civil Eng.*) Framing of piles or other timbered work, sometimes filled up with concrete or masonry. Used for carrying the foundations of submarine work.

Crimp Cloth (*Cotton Manufac.*) A form of cotton weaving in which longitudinal sections of the cloth are uniformly crimped or crinkled purposely. This is caused by weaving warps at different tensions.

Crimson Lake (*Dec.*) A bright red pigment prepared in a somewhat similar manner to carmine (*q.v.*) It is not permanent, and is used by decorators principally as a glazing colour (*q.v.*)

Crinoidal Limestone (*Geol.*) Calcareous rocks of marine origin, which largely consist of the disjointed fragments of the stems of Encrinites. Good examples are presented by some varieties of the Carboniferous Limestone.

Criophorus. Literally "one who carries a ram." Hermes was so named for having saved the people of Tanagra from the plague by carrying a ram round the walls.

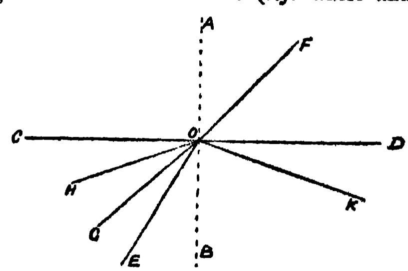
Crio Sphinx. A sphinx with the head of a ram. One of the three varieties of the Egyptian Sphinx, the others being the "Andro Sphinx," with the head of a human being, and the "Hieraco Sphinx," with a hawk's head. *See* SPHINX.

Crisis (*Glass Manufac.*) The period at which the heat of the furnace, after materials are thoroughly fused, is reduced to the temperature required for working the metal.

Crispine (*Cost.*) A headdress similar to the ancient calantica (*q.v.*)

Critic (*Art*). A person who examines works of art critically and pronounces opinion upon their merit or value. Properly an expert who has knowledge of the subject criticised.

Critical Angle (*Light*). Let CD be a surface separating two transparent media, the lower one being the denser of the two (*e.g.* water and air).



Then if a ray EO strike the surface, it will be bent away from the normal AOB, along a line OF, in

accordance with the law of refraction, sin AOF = μ sin EOB. If now the angle EOB be increased, AOF will go on increasing until sin AOF = 1, and the refracted ray passes along OD. When this is the case, the ray in the dense medium makes an angle BOG with the normal, such that

$$\mu \sin \text{BOG} = 1$$
$$\sin \text{BOG} = \frac{1}{\mu}$$

This angle BOG is termed the CRITICAL ANGLE. If a ray make an angle with the normal greater than the critical angle, as at HO, then it suffers TOTAL INTERNAL REFLECTION along a line OK, and does not emerge into the upper medium at all. *See also* ERECTING PRISM.

Critical Pressure (*Phys.*) The vapour pressure of a liquid which is at its critical temperature (*q.v.*)

Critical State (*Phys.*) The condition of a substance which is at its critical temperature and pressure. In this state the liquid and gaseous forms of matter merge into one, a very slight rise of temperature making the substance gaseous, and a very slight reduction of temperature causing partial condensation to a liquid; also in this state both liquid and vapour have the same density, and the latent heat of vaporisation disappears.

Critical Temperature (*Phys.*) The temperature, above which it is not possible to liquefy a gas by the application of pressure, however great: in other words, the temperature above which the substance is absolutely incapable of existing in the liquid state.

Critical Volume (*Phys.*) The specific volume, *i.e.* the volume of unit mass of a substance when at its critical temperature (*q.v.*)

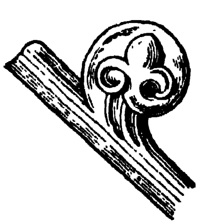
Crizzling (*Glass Manufac.*) Damage caused on the surface of glass by using cold tools whilst it is being manufactured.

Croccin Scarlet. *See* DYES AND DYEING.

Crocidolite (*Min.*) A pseudomorph (*q.v.*), in quartz, of a variety of hornblende (*q.v.*) with a fibrous structure; it has a blue colour, owing to the presence of ferrous oxide; by the change of the latter to ferric oxide the mineral becomes golden yellow. It is used as an ornamental stone. Sometimes termed BLUE ASBESTOS.

Crock (*Pot.*) Utensils of clay of any form are called crocks. Crockery is derived from this term.

Crocket (*Architect.*) A hook-shaped Gothic ornament usually consisting of half-opened leaves. It is used in series on the angles of spires, pinnacles, etc., and on dripstones to doors and windows. The earliest, and perhaps the finest, examples are found in the later part of the Early English period.



CROCKET.
EARLY ENGLISH.
SALISBURY CATHEDRAL.

Crocodile Shears and Squeezer. (*Met., Eng.*) *See* ALLIGATOR SHEARS, *etc.*

Crocoisite (*Min.*) Chromate of lead, $PbCrO_4$. Lead oxide = 68·9, chromic acid = 31·1 per cent. It occurs in reddish-yellow crystals of the Monosymmetric System. It is now a rare mineral. From Siberia, Hungary, and the Philippine Islands.

Cromlech (*Architect., etc.*) *See* PREHISTORIC ARCHITECTURE.

Crop Hides (*Leather*). Well grown heifer or ox hides tanned whole with oak bark, chiefly used by country cobblers. They have been largely superseded by BUTTS and BENDS.

Cropped (*Bind.*) Said of a book that has had its margin cut down too much.

Croppie (*Glass Manufac.*) An iron instrument used for conveying a cylinder of glass to the flattening stone. *See* SHEET GLASS *and* GLASS MANUFACTURE.

Cropping (*Eng., Met., etc.*) Cutting the ends of bars, rails, etc.; especially cutting iron bars into lengths suitable for making into a fagot (*q.v.*)

—— (*Woollen Manufac.*) Relates to the removal or shortening of the nap, pile, or fibre on the face of the fabric, by cutting. The work is done on the cropping or cutting machine.

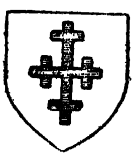
Crore. Ten millions = one hundred lakhs.

Crosier. *See* CROZIER.

Cross (*Eng.*) A name applied to various objects whose form is that of a cross; *e.g.* a four-armed support used in foundries for raising heavy weights: a connecting piece for four pipes or rods which meet at right angles, etc.

—— (*Her.*) This is one of the ordinaries; it is formed from two other ordinaries—the pale and the fess. If not otherwise determined, the cross is placed in the centre of the field, and extends till it meets the outer edges of the shield. The cross exists in many forms. Gwillim enumerates 39 varieties; Leigh, 46; Edmondson, 109; and Robson, 222. The following are among the principal varieties:—*Anchored:* With the limbs terminated in anchors. *Avellane:* With filbert husks at the ends of the limbs. *Botonée* or *Treflée:* Has trefoils at the ends of the limbs. *Botonée Fitchée:* The same as botonée, but with the lower limb pointed. *Calvary:* A Latin cross on steps or on degrees. *Cercelée* or *Recercelée:* The ends of the limbs are floriated. *Champain* or *Pointed:* The ends of the limbs are pointed. *Clechée* or *Urdée:* With a blunt arrowhead at the end of each limb *Couped* or *Humettée:* When the end of each limb is cut off square, so that it does not reach the edge of the shield. *Crosslet:* With each limb crossed. *Crusilly* or *Crusilé:* Several cross crosslets on a field. *Degraded:* A Latin cross on steps (usually three). *Engrailed:* The lines of the cross engrailed. *False:* *See* Voided. *Fimbriated:* With a narrow border to each limb. *Fitchée:* With the lower limb pointed. *Flourie:* With the end of each limb formed into a fleur-de-lis. *Fleurettée:* With a fleur-de-lis attached to the end of each limb and not forming a part of it, as in the last. *Formée:* *See* Patée. *Fourchée:* A cross moline with the curved ends of the fers-de-moline cut off. *Fylfot:* A cross Cramponné. *See* FYLFOT. *Greek:* With limbs of equal length. *Humettée:* *See* Couped. *In Cross:* When charges are arranged crosswise. *Latin:* With the point of intersection placed above the centre of the shield, and the three upper limbs of the same length, but the fourth much longer. *Maltese,* or *Cross of Eight Points:* A variety of cross patée in which the wide extremities of the limbs are

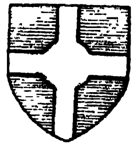
CLECHÉE.



CROSSLET.

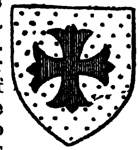
LATIN.

notched or indented. This was used by the Knights Templars and Hospitallers. *Moline:* With the terminations of the limbs formed of fers-de-moline or mill-rinds. *Nowy:* At the centre is a rounded disc which shows between the intersecting limbs. *On Degrees:* *See* Calvary. *Passion:* A Latin cross couped. *Patée* or *Formée:* The limbs are wedge shaped, with the apex at the intersection; they are of equal length, and do not reach the edges of the shield. *Patée Fitchée:* A cross patée with the lower limb pointed.



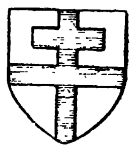
NOWY

Patonce: The limbs are not drawn with parallel lines, but gradually tapering to the intersection; the ends are floriated. *Patriarchal:* A cross with the upper limb crossed by a bar shorter than the central limb. *Pointed:* *See* Champain. *Pommée* or *Pommelée:* With a ball at the end of each limb. *Potent:* With a bar at the end of the limb at right angles to the limb, and of the same length as the limb, called after the fur of that name.



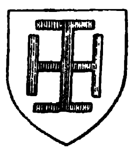
PATONCE.

Potent Fitchée: A cross potent with lower limb pointed. *Potent Quadrate:* A cross potent with intersection as in Quadrate. *Quadrate:* When the centre is square, not round. *Quarter Pierced:* A small square hole at the intersection of the limbs. *Quarterly Pierced:* The whole of the intersection is removed, the limbs only touching and not crossing. *Ragulée:* When the limbs are bounded by lines ragulé. *Rayonnant:* With rays of light springing from the intersection of the limbs.



PATRIARCHAL.

Recercelée: *See* Cercelée. *Saltire*, or *Cross of St. Andrew:* Formed by the intersection of a bend with a bend sinister, similar to a capital X, known as the Cross of St. Andrew; it extends to the edges of the shield. *Tau* or *Cross of St. Anthony:* Has no upper limb; it resembles a T, the Greek equivalent being Tau. *Treflée:* *See* Botonée. *Undée:* With the border lines undé. *Urdée:* *See* Clechée. *Voided* or *False:* When the entire centre of the limbs is cut out, only the outline being shown.



POTENT.

Voided throughout: When the voiding is carried to the ends of the limbs of the cross. *Wavy:* With the border lines wavy. NATIONAL CROSSES:—*England:* Cross of St. George: A red cross on a white ground. *Scotland:* Cross of St. Andrew: A diagonal white cross on a blue ground. *Ireland:* Cross of St. Patrick: A diagonal red cross on a white ground.

Cross, Archiepiscopal. *See under* CROZIER.

Cross Band (*Woollen Manufac.*) Applied to yarns, and meaning that the twine in spinning has been inserted from right to left. *See* OPEN BAND.

—— (*Lace Manufac.*) Breadths of lace made crosswise of the lace machine. Good effects may be obtained by this method, but the length of each breadth is limited to and determined by the width of the machine.

Crossbow (*Arms*). A missive weapon consisting of a bow fixed to a grooved stock or barrel which held the missile, and a mechanism for bending the bow, some of the largest being furnished with a windlass for this purpose. It was the favourite weapon of the Genoese, and was also used by the Swiss, the French, the Germans, and the Chinese. In England it was superseded at an early period by the handier and more deadly longbow, which could be fired four times as quickly. The missile generally used with the crossbow was the square-headed bolt or quarrell.

Cross Bred (*Woollen Manufac.*) A term applied to medium-stapled wools, and indicative of the crossing of fine and medium wool sheep, etc.

Cross Course (*Mining*). A vein running into or out of another one at an angle.

Cross Cut Chisel (*Eng.*) A narrow cold chisel. *See* COLD CHISEL.

Cross Cut File (*Eng.*) *See* DOUBLE CUT FILE.

Crossed Arm Governor (*Eng.*) *See* GOVERNORS.

Crossed Lens (*Light*). A biconvex lens in which the curvatures of the two surfaces are unequal. This construction can be made to give less spherical aberration (*q.v.*) than that produced by a biconvex lens whose surfaces have the same curvature.

Cross Girders (*Eng.*) Short bars or girders acting as side struts or ties between two longer girders.

Cross Hatching. Engraving or hatching a surface with series of parallel lines, one series crossing the other. In drawings and engravings shading is effected by this method.

Cross Head (*Eng.*) The structure fixed to the end of a piston rod to which the connecting rod and the slide blocks (*q.v.*) are attached; also a bar, plate, etc., fixed to the end of the plunger of a hydraulic press or ram.

Cross Heading (*Mining*). A drift or passage from one level to another for ventilating purposes.

Crossings (*Eng.*) Spaces left in the rails when one set of lines crosses another on a railway; they allow the flanges on the wheels to pass through when a train is running on a set of rails which crosses another set at an angle.

Cross Magnetisation (*Elect. Eng.*) The production of magnetic lines in the armature of a dynamo or motor, due to the current flowing through its own coils; inside the iron of the armature these lines are approximately at right angles to the lines sent through the armature by the field magnets. The effective field in the air gap acting on the armature conductors is the resultant of the cross field and the original field, and is equivalent to a rotation of the original field in the direction of motion in the case of a dynamo, and in the opposite direction in the case of a motor. If there be a lead to the brushes, a demagnetising effect will also be produced.

Cross, Monumental. The eleventh century saw the commencement of the use of these on gravestones, sometimes incised, sometimes in low relief. Examples are still extant of the plain linear cross, but more often it was adorned with floriated ornamentations on the upper limbs, and the elongated shaft was generally enriched. When monumental brasses were introduced, some bore the cross, either plain or sometimes showing elaborate enrichments, with or without figures kneeling at the base or within the opened out heads or at the intersection of the upper limbs of the cross. *Initial Crosses* are to be found at the beginning of monumental inscriptions: a plain Greek cross was generally used.

Cross, Pectoral. A cross worn on the breast by high ecclesiastics and royal personages. Notable examples: St. Cuthbert's Cross at Durham, Dagmar Cross in Denmark.

Cross Section. (1) A cut across any object at right angles to its length or to some other specified line. (2) A drawing of such a section.

Cross Slide (*Eng.*) The part of a planing machine which carries the tool box, and along which the latter can be moved in a direction at right angles to the traverse of the table of the machine.

Cross Tongue (*Carp. and Join.*) A thin slip of wood with the grain at right angles to its length. It is used to form the tongue in a tongued and grooved joint when extra strength is required.

Cross Tubes (*Eng.*) This term is usually applied to tubes running horizontally through the firebox of a vertical boiler. *See* BOILERS.

Cross Wind (*Woollen Manufac.*) A method of winding the yarn on to a bobbin, with a short cross traverse.

Crotal (*Archæol.*) An ancient rattle, or castinets made of bone or wood. Used perhaps as an accompaniment to dancing.

Crotchet (*Music*). *See* NOTES.

Croton Compounds (*Chem.*) CROTONIC ALDEHYDE, $CH_3CH : CH . CHO$, a liquid with irritating odour and boiling at 104°, is obtained by the condensation of aldehyde on heating with zinc chloride. On careful oxidation it yields CROTONIC ACID, an acid capable of existing in two stereoisomeric forms. *See* STEREOISOMERISM.

$$\begin{array}{c} CH_3 . CH \\ \| \\ HC . COOH \end{array} \qquad \begin{array}{c} CH_3 . C . H \\ | \\ HOOC . C . H \end{array}$$

The ordinary form melts at 72°.

Croton Oil. A powerful irritant drug obtained from the seeds of *Croton Tiglium* (order, *Euphorbiaceæ*) by pressure. The plant is a native of the East Indies.

Crowbar. A long bar of iron with a claw at one end. Sometimes the end is flattened or chisel-like, without being formed into a claw. Used as a wedge or lever for a variety of purposes.

Crown. Originally a crown was a wreath composed of flowers, or leaves of laurel, oak, olive, etc. Such crowns were awarded by the Greeks and Romans to victors in public games and to citizens who had greatly benefited the State. Eventually such crowns were made of gold. In modern times the crown is the badge of sovereignty, and forms the covering for the head of a monarch on State occasions. The English crown consists of a cincture of gold adorned with precious stones, and having alternately four Maltese crosses and four fleurs-de-lis. From the crosses spring arches, surmounted at the point of intersection by a mound and cross. The crown so formed encloses a crimson velvet cap having an ermine border. Coronets (*q.v.*) are without the arches. The crown of Charlemagne, which is still preserved in Vienna, is composed of eight plates of gold varying alternately in size and connected by hinges, the larger plates being jewelled and the smaller ones ornamented with enamels. The front plate of this crown is surmounted by a cross.

THE ENGLISH ROYAL CROWN.

—— *Her.* The heraldic crown has various forms, and generally has one or more arches. The earlier form of crown differed only slightly from the coronet.

—— (*Build.*) The highest part of an arch. *See* ARCH.

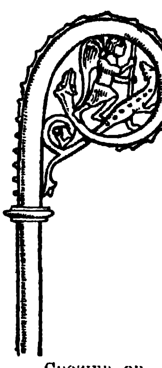
Crown Glass. This is now used principally for mosaic picture windows, the varying tints of the circles or sheets, due to its irregular thickness, being an advantage, and the necessity of flattening is avoided. It has a more brilliant surface than either sheet or plate glass, but owing to its method of manufacture the surface is not so regular, and the diameter (the sheet is circular) does not exceed 70 in. The bull's-eye in the centre further reduces, to a considerable extent, the size available for use. *See* GLASS MANUFACTURE.

Crown Leather. Known also as PRELLER'S LEATHER and HELVETIA. Made first, fifty years ago, by Preller, and stamped with a crown. The leather is prepared by drumming (*q.v.*) hides in mixture of oil, fat, flour, and salt. Used for belt laces and light belting.

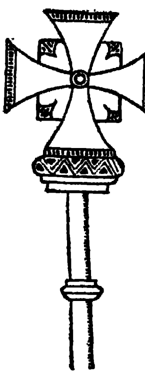
Crown Wheel (*Eng.*) A toothed wheel with the teeth at right angles to the plane of the wheel. Used in certain cases instead of bevel wheels for connecting two shafts at right angles.

Crow Step Gable (*Architect.*) *See* CORBIE STEP GABLE.

Crozier. The sign of office of a bishop or abbot. It is in the form of a shepherd's staff with a crooked end. The staff used by an archbishop is surmounted by a cross.



CROZIER, OR PASTORAL STAFF. THIRTEENTH CENTURY.



ARCHIEPISCOPAL CROSS.

Crucible (*Metallurgy*). A pot in which melting operations are carried on. Made of some form of porcelain, fire-clay, magnesia, plumbago, graphite, lime, or a special refractory mixture. A good crucible should withstand the highest temperature to which it is liable to be subjected, without fusion. It should also bear any sudden changes of temperature without fracture, and be unacted on by the materials which it may contain. For certain chemical purposes small crucibles are made of platinum.

Crucible Steel (*Eng.*) Cast steel (*q.v.*) made by the cementation process.

Crucible Tongs (*Met., Chem., etc.*) Tongs with jaws suitably shaped for lifting crucibles.

Crucifix. A figure representing the dead or dying form of Christ on the Cross.

Crude Carbolic. *See* GAS MANUFACTURE: COAL TAR DISTILLATION.

Crude Oil. *See* GAS MANUFACTURE: COAL TAR DISTILLATION.

Crup Butt (*Leather Manufac.*) The crup is a small portion of the horse hide. It is cut from the portion over the loins of the horse, is more waterproof than the other part, and on account of its greasy and soft nature is valuable for the uppers of boots, especially shooting or fishing boots.

Crushing Strain (*Eng.*) A strain caused by simple compression.

Crust of the Earth (*Geol.*) A term applied, somewhat vaguely, to such parts of the earth's outer envelope as are accessible to human observation, or which there is reason to think are represented by any kind of rock now appearing at the surface.

Crutch (*Clocks, etc.*) The lever fixed to the verge or pallet arbor (*q.v.*) of a clock for the purpose of conveying energy from the pallets to the pendulum.

Crutch-head. (*Her.*) Known as Potent (*q.v.*)

Crutcher (*Chem., Eng.*) A wooden plunger used to agitate soap in the cooling frames. The act of "crutching" prevents the soap separating into two liquids, and also incorporates the materials used for "filling" (*q.v.*) Special crutching machines are now made on the Archimedean screw principle.

Cryohydrates (*Phys., Chem.*) If a solution of a salt be made of a particular strength depending on the nature of the salt, and this solution be cooled to a particular temperature also depending on the nature of the salt, the whole solution solidifies; the solid thus produced is called a CRYOHYDRATE. At one time cryohydrates were thought to be definite compounds, but it is now known that they are only mixtures. The cryohydric temperature is the lowest that can be obtained by mixing the two components. For water and salt the proportions are 76·2 to 23·8, and the cryohydric temperature is $-22°$.

Cryolite (*Min.*) A fluoride of aluminium and sodium, $3NaF.Al_2F_3$. Aluminium = 13, sodium = 32·8, fluorine = 54·2 per cent. It is a white lamellated mineral with a perfect cleavage; small fragments fuse easily. It is a source of aluminium, and is also used in the manufacture of a porcelain glass. It comes chiefly from West Greenland.

Cryophorus. A piece of apparatus to show that water becomes cooled by its own evaporation. It consists of two glass bulbs connected by a glass tube. This is partly filled with water, which is boiled to expel air and then sealed up while steam is issuing. To use it, the water is collected in one bulb and the empty bulb placed in a freezing mixture; then the rapid condensation of vapour in one bulb sets up rapid evaporation in the other, with the result that the water falls in temperature until it freezes.

Crypt (*Architect.*) A chamber in a building below the level of the ground.

Crystal (*Min.*) A crystal is a geometric solid composed of a substance of definite composition, with a definite internal arrangement of the molecules. Crystals are, in the great majority of cases, bounded by plane surfaces called FACES; each geometric figure or FORM, many of which may be combined in one crystal, consists of two or more faces. For the various types of crystals, *see* SYSTEMS OF CRYSTALS.

Crystalline Rocks (*Geol.*) Strictly speaking, this term may be applied to any rocks in which a crystalline structure can be made out. More usually, however, the term has now come to mean rock other than the normal or unaltered forms of stratified rocks. Thus gneiss, granite, diorite, and various other rocks of eruptive origin, as well as schists, are understood to come under this designation.

Crystallisation. The process of formation of crystals (*q.v.*) The material must, as a rule, be in the liquid state, thus permitting a free movement of the molecules, which can then take up the definite regular arrangement which is an essential feature of a crystalline substance.

Crystallites (*Min., etc.*) A convenient designation for the embryo stages of development from which crystals of rock-forming silicates afterwards arise. In an arrested stage of development crystallites are often met with in eruptive rocks of vitreous structure.

Crystallographic Notation (*Min.*) The method of indicating the relation of a given crystallographic form to the axes of the crystal. There are many different notations; the one most used now is Miller's, in which the indices are integral numbers proportional to the reciprocals of the various intercepts on the axes.

Crystallographic Systems (*Min., etc.*) *See* SYSTEMS OF CRYSTALS.

Crystallography. The science dealing with the forms and nature of crystals. *See* SYSTEMS OF CRYSTALS.

Crystalloids (*Phys.*) Bodies capable of rapid diffusion when in solution, as opposed to COLLOIDS (*q.v.*) The majority of them can be crystallised; hence the name.

Crystals, Systems of (*Min., etc.*) *See* SYSTEMS OF CRYSTALS.

Cs (*Chem.*) Symbol for Cæsium (*q.v.*)

Cu (*Chem.*) Symbol for Copper (*q.v.*)

Cube. A regular solid whose faces are six equal squares.

Cubebs (*Botany*). *Piper cubeba* (order, *Piperaceæ*). The drug is, like pepper, the dried unripe fruit.

Cubic Space (*Hygiene, Ventilation*). The cubic capacity of a room is ascertained by multiplying the length by the width and then by the height. It is a fallacy to suppose that air space does away with the necessity for the renewal of air. Even the air of the largest rooms will in time become vitiated. Basing calculations on the amount of carbon dioxide exhaled per individual per hour, it is found that each person requires 3,000 cubic feet of air during that period. The free air space provided for each person should be not less than 1,000 cubic feet, provision also being made for renewal of the air three times in the hour. Unfortunately this standard is not often reached. The following shows the cubic space per individual in various places:

Schools	130	cubic feet per head.
Common Lodging Houses	300	" "
Factories and Workshops	250	" "
Barracks	600	" "

In hospitals a much greater amount of cubic space should be allowed.

Cubic System (*Min.*) One of the crystal systems. Also called ISOMETRIC, TESSERAL, REGULAR, and MONOMETRIC. In it there are three axes, all equal and all at right angles, so that no one can be regarded as the principal. There are nine planes of symmetry. *See* SYSTEMS OF CRYSTALS.

Cucurbit (*Chem. Eng.*) The body of a still: the belly of an alembic or retort.

Cuir Bouilli, Cuir Bouilly. Boiled leather. The term was sometimes applied to leather armour used in the Middle Ages. Cuir bouilli was often ornamented by impression and manufactured into various articles of dress. In the sixteenth century it was used for hangings for rooms, and when decorated with gold or silver was known respectively as CUIR DORÉ and CUIR ARGENTÉ.

Cullet (*Glass Manufac.*) Waste glass from broken articles, etc., used for mixing with raw material to aid fusion.

Culm (*Botany*). The jointed stem of certain plants, such as grasses. A synonymous term is HAULM.

—— (*Geol.*) A local name for an impure form of coal found in the Carboniferous rocks of Devonshire. The rocks in which it occurs are often called the Culm Measures. Some of its members are true radiolarian cherts, formed in deep sea water. The stratigraphical position of the Culm Measures may be near the top of the Yoredale Series.

—— (*Mining*). Waste coal mixed with rubbish.

Culvert (*Civil Eng.*) A small tunnel for carrying water.

Cumene (*Chem.*), $C_6H_5 . CH\begin{cases} CH_3 \\ CH_3 \end{cases}$ (Isopropyl benzene), a colourless liquid boiling at 153°: dilute nitric acid oxidises it to benzoic acid. It occurs in coal tar. Prepared by action of isopropyl bromide on benzene in presence of aluminium chloride.

Cumulo Stratus (*Meteorol.*) *See* CLOUDS.

Cumulus (*Meteorol.*) *See* CLOUDS.

Cup. An ornamental vase, with or without handles, mounted on a foot. Originally intended to drink out of.

—— (*Cycle*). The hollow piece which forms the ball race of a ball bearing (*q.v.*)

Cup and Ball (*Gasfitting*). A universal joint on the ball and socket principle, used for hanging gas pendants.

Cupboard. An arrangement of shelves sometimes enclosed with doors. Of great variety of form, and varying from a few simple boards fastened in a recess to elaborate carved pieces of furniture.

Cup Chuck, Bell Chuck (*Eng.*) A chuck with a cylindrical hollow, into which objects to be turned are driven, and held in the hole by friction, by wedges, or by set-screws passing through the wall of the chuck. Chiefly used for light work or for ornamental turning.

Cupel (*Assaying, Chem., etc.*) A small shallow dish of bone ash or some other absorbent material, used when the operation of CUPELLATION (*q.v.*) is conducted on a small scale.

Cupellation (*Assaying, Chem., etc.*) The process of separating a metal from others more readily oxidised, by heating with exposure to air on a hearth made of some porous material which will absorb all or part of the oxides produced, while the metal it is desired to obtain remains as a fused regulus at the bottom of the hearth. Such a porous hearth is called a cupel, and is made of bone ash or a cheaper substitute (mixture of clay and limestone). An example is the separation of silver from lead. *See* LEAD.

Cup Leather (*Eng.*) A leather ring, produced by forcing a flat ring of leather into a mould until its cross section becomes the shape of letter U. Used as packing for the pistons of pumps and hydraulic rams. The material is technically known as HYDRAULIC LEATHER (*q.v.*)

Cupola (*Architect.*) A curved or cup-shaped roof, covering a square, polygonal, or circular chamber. This form of roof is also known as a DOME (*q.v.*)

—— (*Met.*) A cylindrical iron furnace lined with firebrick: used for melting cast iron in the foundry. It is worked by means of a blast, and has the necessary openings for introducing the charge and for withdrawing the slag and fluid metal.

Cupola Blast Furnace (*Metallurgy*). A small form of blast furnace built with an external iron case, like a cupola.

Cupric Compounds, Copper. *See* COPPER COMPOUNDS.

Cuprite (*Min.*) The red oxide of copper, Cu_2O. Copper = 88·8, oxygen = 11·2 per cent. It crystallises in octahedra of the Cubic System, but is also found massive, earthy (TILE ORE), and in capillary crystals (CHALCOTRICHITE). It is worked as an ore of copper. Good crystals have an adamantine lustre, are translucent, and of a deep ruby red colour. From many Cornish mines, Devonshire, Spain, France, Siberia, Lake Superior, Australia, etc.

Cuprous Compounds. *See* COPPER COMPOUNDS.

Cuprum, Cupric, Cuprous. Cuprum is the Latin name for copper, and from it is derived the symbol for copper, Cu. Copper forms two series of salts: those containing more copper are called cuprous, those containing less are called cupric, salts. *See* COPPER COMPOUNDS.

Curare *or* **Curara** (*Botany, Chem.*) The well known arrow poison of South America; is obtained by maceration of the bark of *Strychnos toxifera* (order, *Loganiaceæ*). Used in medicine. It is said to contain an alkaloid termed CURASINE, but this is probably not a single substance.

Curator. A person in charge of a picture gallery or museum.

Curb (*Carp.*) (1) The horizontal timbers under the sill of a lantern light. (2) The plate to which the feet of the top rafters and the top ends of the lower rafters are fixed in a Mansard roof.

—— (*Chem. Eng.*) The upper, conical, or barrel-shaped part of a soap-kettle or copper where it is widened to prevent boiling over. A Fan Curb is a modern form in which two paddle wheels or beaters on a horizontal shaft are operated beneath the surface of the soap by a vertical shaft and bevel gear.

—— (*Mining*). The frame used in sinking a shaft, which supports the lining.

—— *or* **Curb Ring** (*Eng.*) An annular wheel (*q.v.*) fixed on the bed plate of a crane and used for rotating the crane.

Curcumin (*Chem.*), $C_{14}H_{14}O_4$. Orange-yellow prisms melting at 178°: it is the colouring matter of turmeric root: obtained from the root by extraction with ether after it has been distilled with steam; it is a weak acid. Alkalis turn it brown. The action of boric acid is characteristic; this acid turns it reddish brown. Hydrochloric acid does not change this colour, while acids change the brown produced by an alkali back to yellow.

Curd of Milk (*Foods*). When an acid is added to milk, curds and whey are formed. The former consists of casein (the proteid of milk) and fat, while the liquid whey contains the sugar, salts, etc. The curd of cow's milk is not so digestible as that of human milk; this may be counteracted by adding barley water and lime water to milk intended for infants. Cheese is prepared from the curd, while casein is always present in butter. *See* COW'S MILK.

Cure (*Leather Manufac.*) A material or solution of a material capable of curing or arresting the decomposition of animal hides or skins. The most common "cures" in use are salt, arsenic, boracic acid, and compounds of carbolic acid. *See also* DEPICKLING.

Curing (*Leather Manufac.*) Treating hides or skins with a cure (*q.v.*), generally for the purpose of preserving them during transport.

Curiosities (*Art, Archæol.*) Objects of interest, valued for their antiquity, rareness, or costliness.

Curl Yarn (*Woollen Manufac.*) A compound thread in which one of the strands is formed into curls or loops.

Current Bedding (*Geol.*) Another term for what is more usually known as FALSE BEDDING or as CROSS STRATIFICATION. The rocks in which it occurs are usually either sandstones or conglomerates. In all cases the planes of original deposition were not parallel to the horizon. The structure is due to deposition by the action of bottom currents.

Current Density (*Elect. Eng.*) The amount of current per unit of area of cross section of a conductor. A common rule for determining the size of a conductor is to allow 1,000 ampères per square inch, but this requires much modification according to the depth to which the conductor is covered and its facilities for radiating away the heat produced by the passage of the current. This rule only takes into consideration the heating limit, and is useful in wiring buildings. In main conductors for supplying current from central stations the current density is determined by the percentage loss of energy in them, which usually becomes excessive long before the heating limit is reached.

Current, Electric. Electricity in motion, flowing from place to place along a conductor.

Currying (*Leather Manufac.*) A process by which grease is put into tanned leather to make it pliable and water resistant. Harness, belting, boot uppers, straps, etc., are always curried.

Curtail Step (*Carp. and Join.*) A step with a scroll end.

Curtain (*Chem. Eng.*) The sheet lead portion of a vitriol chamber suspended over the "saucer." It resembles a rectangular box suspended upside down over its lid, the lid being the "saucer." The mouth of the curtain is sealed by a layer of acid in the saucer.

Curtain Machine (*Lace Manufac.*) A twist lace machine especially adapted for the production of lace curtains. The principal feature is its capacity for the reproduction of design on an extensive scale.

Curule Chair. *See* CHAIR, CURULE.

Curvature. The curvature of a line is measured by the reciprocal of its radius of curvature (*q.v.*). The curvature of a surface is the sum of the curvatures of two cross sections of the plane, made by two planes cutting the surface at right angles to each other.

Curve Ranging (*Surveying*). Marking out on the ground a series of points through which a curve of a given radius passes.

Curves, Magnetic. *See* LINES OF FORCE.

Curves of Magnetisation (*Elect. Eng.*) Curves showing the relation of the magnetising force to the intensity of magnetisation or to the magnetic induction produced by it in any given sample of iron or steel.

Curvilinear (*Architect.*) One of the periods into which Sharpe divided English Gothic architecture. His division, based on the form of the windows, is as follows:

Anglo-Saxon	449—1066
Norman	1066—1149
Transitional	1149—1190
Lancet	1190—1245
Geometrical . . .	1245—1315
CURVILINEAR . . .	1315—1360
Rectilinear . . .	1360—1550

The windows of the curvilinear type have tracery in which the bars are formed into undulating curves (flowing tracery) or tracery formed in reticulated or netlike forms. *See* DECORATED *and* RETICULATED.

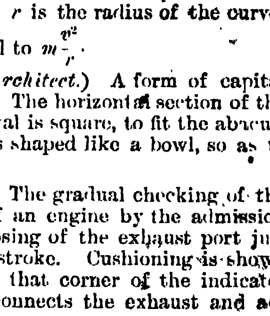
Curvilinear Motion. Motion along a curved line. To maintain such motion of a body a force must be exerted on it directed towards the centre of curvature of the curve. If v is the velocity and m the mass of the body, and r is the radius of the curve, the force must be equal to $m\frac{v^2}{r}$.

Cushion Capital (*Architect.*) A form of capital used in Norman work. The horizontal section of the upper part of this capital is square, to fit the abacus, while the lower part is shaped like a bowl, so as to fit a circular shaft.

Cushioning (*Eng.*) The gradual checking of the motion of the piston of an engine by the admission of steam or by the closing of the exhaust port just before the end of the stroke. Cushioning is shown by the rounding off of that corner of the indicator diagram (*q.v.*) which connects the exhaust and admission lines.

Cushion Tyre (*Cycle, etc.*) A tyre consisting essentially of a very thick-walled rubber tube, the walls of the tube itself being thick enough to supply a certain amount of resilience without inflation. Cushion tyres may be said to have been intermediate between the old solid tyres and the modern pneumatics, but they were always unsatisfactory, and are practically extinct.

Cusps (*Architect.*) The projecting points producing the leaf-shaped forms or foils of Gothic tracery. In the Early English period, during which cusps were introduced, they were worked on the soffit of the tracery bar or arch, and had the appearance of having been attached to it as an afterthought. In later work the inner moulding of the bar adjacent on the soffit was continued on the cusp, so that the latter appears to be an essential part of the tracery bar. *See* FOILS.



CUSP.

Cut (*Art*). A print from a wood block is sometimes called a "cut." *See* CUTS.

—— (*Cotton*). A woven piece length of cloth.

—— (*Eng., etc.*) A process of removing metal or wood by means of a cutting tool. "Heavy" cut, "light" cut, etc., are usual expressions referring to the amount of material removed at a time.

—— (*Linen Manufac.*) When the yarn is being reeled into hanks, the latter are made up of small parcels of a hundred and twenty threads, or 300

yards in length, which are called CUTS or LEAS. There are usually twelve cuts to one hank, but sometimes only ten. *See* CUTS.

Cut and Mitred String (*Join.*) A cut string (*q.v.*) used in a staircase in which there are no ornamental brackets to conceal the junction of the risers (*q.v.*) with the string. The junction is made in this case by means of a mitred joint. *See also* STAIRCASES.

Cuticle (*Botany*). The outer layers of the walls of epidermal cells. The original cellulose of the wall becomes converted into a strong waterproof substance—CUTIN. *See* RAFFIA.

—— (*Zoology*). (1) A thin membrane formed by a SECRETION (chitin) of the outer surface of many invertebrate animals (example, earthworm, crayfish, etc.) (2) The outer or horny layer of the epidermis of the mammalian skin. It is composed of dead cells, whose protoplasm is converted into KERATIN (*q.v.*)

Cutlas (*Arms*). A short heavy sword with a wide curving blade, intended rather for cutting than thrusting. This weapon was formerly used by sailors.

Cut-Off (*Eng.*) The point at which the admission of steam to a cylinder is stopped. It usually varies from a quarter to threequarters of the stroke, and is determined by the lap (*q.v.*) in the case of the ordinary slide valve. Variable cut-off is obtained by the use of a separate valve called the Expansion Valve in ordinary engines, or by controlling the action of the admission valves in Corliss engines.

Cuts (*Typog.*) A term used by printers for illustrations of any kind.

—— (*Woollen Manufac.*) The Scotch term for counts (*q.v.*) Galashiels cut is a length of 300 yards in 24 oz., and the Hawick cut the same length in 26 oz.

Cut String (*Join.*) A string (*q.v.*) in a staircase which has its upper edge cut out into a succession of rectangular notches, the edges of the notches being alternately vertical and horizontal, corresponding to the risers and treads (*q.v.*)

Cutter (*Build.*) A soft brick used in gauged arches. Also termed a RUBBER or RUBBING BRICK. *See* BRICKS.

—— (*Eng., etc.*) The actual cutting part of a machine tool, especially the rotating cutting wheel used in milling, wheel cutting, and similar machines.

Cutter Block (*Eng., etc.*) The holder which carries the tool. The term is especially applied to woodworking machinery.

Cutters (*Geol.*) A term for a set of JOINTS (*q.v.*) cutting through a rock at right angles to the set termed BACKS (*q.v.*)

Cutting (*Civil Eng.*) An open trench by which a railway, etc., is carried through ground of moderate elevation. The material of the cutting is used to form embankments on one or both sides of the hill, giving gradual approaches to the cutting, and utilising the material removed without the necessity of transport to a distant point.

—— (*Chem. Eng.*) The separation of soap (in the soap-copper) from the glycerol and aqueous fluids in the half-made or "close" soap, by the addition of salt or brine, in which the grain soap is insoluble. Also termed GRAINING.

Cutting Blast (*Metallurgy*). Air forced into a furnace under too high a press— wasteful consumption of fuel.

Cutting Edge (*Eng., etc.*) The actual edge of a tool. The angle varies with the nature of the material, being usually most acute for the softest materials.

Cutting Face (*Eng., etc.*) The flat surface of a cutting tool, which serves to turn over or break the shaving as it is removed.

Cutting Gauge (*Carp., etc.*) A gauge for cutting thin wood. It resembles a marking gauge, but has a sharp-edged cutter instead of a scribing point, so that it makes a cut instead of a scratch on the surface, and can therefore be used for dividing thin material.

Cutting Up (*Foundry*). When fresh sand is to be added for mending a broken part in a mould, the surface of the broken part is first roughened, in order that the new sand may adhere properly. This roughening is termed CUTTING UP.

Cuttlefish. *Sepia officinalis* (class, *Cephalopoda*). A naked mollusc, possessing an internal shell or CUTTLE BONE. The sepia is used as food in many countries, while the "bone" forms a polishing material, and the ink bag is the source of the pigment SEPIA (*q.v.*)

Cuvette (*Glass Manufac.*) The vessel in which molten plate glass is carried to the casting table.

—— (*Met.*) A Parting Flask (*q.v.*)

Cyanic Acid (*Chem.*), HCNO. A liquid only stable below 0°; above this it polymerises to a white solid called cyamelide. It is prepared by heating cyanuric acid, $H_3C_3N_3O_3$. From cyanic acid the salts called cyanates are derived. Only one form of cyanic acid is known; but there are two formulæ possible for it, namely (1) N ⋮ C . OH ; (2) HN : CO. Salts derived from form (1) are called CYANATES; salts from form (2) are called ISOCYANATES. *See* TAUTOMERISM.

Cyanides (*Chem.*) Salts of hydrocyanic acid (*q.v.*) *See* POTASSIUM CYANIDE, *under* POTASSIUM COMPOUNDS, *and* MERCURIC CYANIDE, *under* MERCURY COMPOUNDS. The organic cyanides are called NITRILES (*q.v.*)

Cyaniding (*Met.*) A method of extracting gold from "slimes" (*q.v.*) and poor ores by treating them with a solution of alkaline cyanide which dissolves the gold.

Cyanite (*Min.*) *See* ANDALUSITE.

Cyanogen (*Chem.*), $\begin{array}{c} C \vdots N \\ | \\ C \vdots N \end{array}$. A colourless gas with characteristic smell: extremely poisonous: somewhat soluble in water (1 in 4), but the solution decomposes, giving ammonium oxalate, a brown solid called azulmic acid, and other products. It burns with a purple flame to nitrogen and carbon dioxide. With caustic potash it gives a mixture of potassium cyanide and cyanate. It is obtained by heating mercuric cyanide or a mixture of potassium cyanide and copper sulphate solutions.

Cyanotype (*Photo.*) *See* BLUE PRINT.

Cyanuric Acid (*Chem.*), $C_3H_3N_3O_3$. A white crystalline solid readily soluble in hot water and in alcohol. When heated it gives cyanic acid (*q.v.*) It is obtained on heating urea.

Cyathus (*Archæol.*) A drinking cup or small ladle used by the Greeks and Romans for drinking wine or for drawing it from the crater (*q.v.*) It was also a measure = about one-twelfth of a pint.

Cycle. (1) A complete set of physical or chemical operations, such as the processes undergone by the working substance in the cylinder of an engine. (2) A general term for a light vehicle propelled by the rider. The legal expression, still frequently used in patent specification, is "Velocipede." *See* CYCLES.

Cycles. A modern cycle consists of four chief sets of parts: (1) the frame, (2) the wheels, (3) the tyres, (4) the equipment, which includes the saddle, brakes, chain, ball bearings, etc. The frame is generally formed of thin seamless steel tubing, which is "solid drawn" (*q.v.*) There is also a form of tube known as "helical," which is formed from a thin steel band or ribbon, wrapped into the form of a tube and brazed at the edges. It is immensely strong, and is quite distinct from the inferior form of tube known as "lap welded," which is used in some low-grade machines. The joints at the points where the tubes meet or are joined together to form the frame are made by means of "lugs," which are "drop forged" in the best machines, *i.e.* are forged as solid pieces from suitable steel under a mechanically worked hammer. The lugs are drilled out to fit the tubes, which are then brazed in, or in the case of "flush joints" the lug goes inside the tube, which is brought up close to the head of the lug, thus making a very neat joint. The wheels consist of a steel rim, which may be either hollow or solid. The rims are generally mechanically rolled and shaped from flat steel strips; the overlapping ends are brazed together and ground until the joint is smooth and imperceptible when enamelled. In the best form the rim is stamped from one piece of steel, without any joint whatever. It is then "spun" into shape and provided with a liner to strengthen it and take the tyre. The spoke heads are provided with washers to prevent them pulling through the thin rim. The wheel rim is attached to the hub by means of steel wire spokes (about ·05 in. in diameter), which are in tension instead of being adapted merely to take compression, as is the case in the wheel of an ordinary vehicle. It was the discovery of the "suspension" method of building a wheel in 1868-9 which enabled a cycle to be made of the light materials now used; for if the spokes had to be in compression, they would have to be sufficiently stiff to withstand bending, and therefore enormously heavier than at present. The hub of a bicycle wheel is shown in figs. 1 and 2. In both cases A represents the axle, which does not rotate, but is fixed by a locking nut N to the fork F. The rotating portion, or hub proper, is shown in section at H, the spokes being attached to the flange at S. The hub is bored out to a larger size than the axle, so that the barrel of the hub does not come into contact with the fixed axle at all, but acts as an oil retainer. The actual bearing surface is produced by contact with steel balls BB. In fig. 1 there is a conical collar on the axle, and the hollow cone C is screwed into the hub until there is easy contact between the cone on the axle, the ball B, and the hollow cone C, the space between these forming the ball race. In the second case, fig. 2, the cone C is screwed on to the axle, and can be moved backward and forward to make an adjustment of the bearing until the ball B is in touch with this and the hollow cone in the hub. In the case of the back wheel the chain wheel or pinion is attached to the hub itself by a screw thread; the axle is held in a slot in the rear fork ends, and by means of an endless screw can be drawn back in order to tighten the chain. In the front wheel the hub turns freely, without any control, on the fixed axle. The lowest part of the frame is termed the BOTTOM BRACKET, and is shown in fig. 3. The crank axle which runs through the bottom bracket can turn freely in the ball bearing shown. On to this axle the cranks and the chain wheel are rigidly keyed. Sometimes the crank arm and axle are in one—the other crank being secured by a chain attachment. This chain or SPROCKET WHEEL is connected by the steel chain, which forms the driving band described below, to the small chain wheel which is fixed to the hub of the back wheel. In the older type of machine, known as the FIXED WHEEL machine, the chain wheel and hub must turn together at all times; but in modern machines the wheel is said to be "free," that is the sprocket wheel, rear pinion, chain, cranks, and pedals may remain stationary, while the rear wheel runs freely. A form of free-wheel clutch is shown diagrammatically in fig. 4. A is a wheel or rim which is rigidly fixed to the hub, and must always turn with it; it carries pawls or ratchets D; B is a steel rim provided with teeth CC, and BB are the ball bearings. The ratchets or pawls D are either

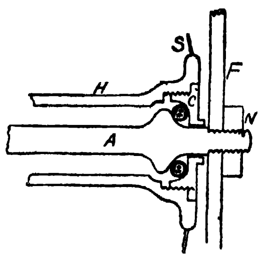


FIG. 1.

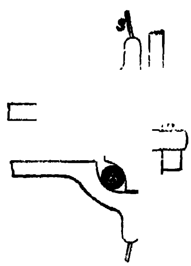

FIG. 2.

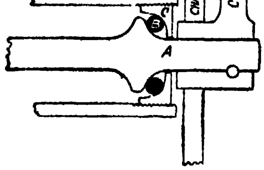

FIG. 3.

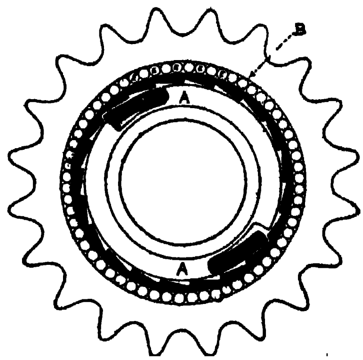

FIG. 4.

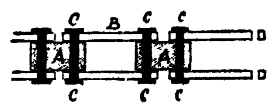

FIG.

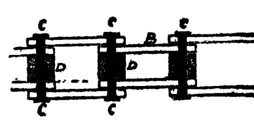

FIG. 6.

caused to drop between the teeth CC of the ratchet wheel by springs, or, in the more popular machines, are actuated by gravity. It is easily seen that if the outer portion B remain at rest, the inner portion A can revolve in the direction of the hands of a clock; but if B revolve, it is bound to carry A with it. When the cycle is pedalled, B will be driven by the chain in such a manner that A revolves with it; on ceasing to pedal, the rim B remains still, and the machine runs on, causing A to revolve in the same direction as before, the pawls D dropping automatically and passing each tooth in turn. Thus the back wheel of the cycle can continue to revolve, and the machine runs on, while the pedals, cranks, chain, and the outer part B of the wheel all remain at rest. In what is termed the "clutch" form of freewheel the connection between A and B is made by some form of friction clutch; but this is now being abandoned in many forms of machine in favour of some type of ratchet wheel, which is more certain in its action. *Chains:* There are two main types of chain, shown in figs. 5 and 6. In fig. 5 a series of solid blocks AA are connected to side links B by means of pins CC, forming what is termed a BLOCK CHAIN. In the second type the side link B is connected by pins CC, which pass through rotating rollers D, forming what is termed the ROLLER CHAIN. In this form the friction of the chain is diminished to a considerable extent. Friction is further diminished by protecting the

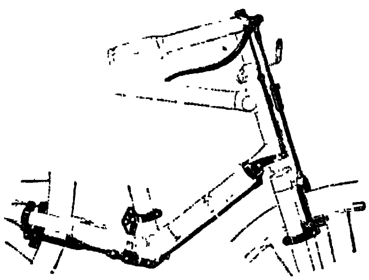

FIG. 7.—B.S.A. BICYCLE BRAKE FOR ORDINARY FRAME.

chain from dust and grit. The best method of doing this is to enclose both chain wheels and the whole of the chain in a thin metal GEAR CASE, which contains a small bath of oil, through which a portion of the chain is continually running, thus keeping the whole well lubricated and free from grit. The STEERING PILLAR is the upright rod by which the front forks are connected with the handle bar; over this is the outer sleeve to which the upper and lower frame tubes are joined; at the top and bottom of this sleeve are placed ball bearings in the head of the machine, and form a practically frictionless joint between the frame and front portion of the cycle. The pedals also run on ball bearings. By this means internal friction is reduced to a minimum. What may be termed the external friction—that due to the road—depends largely on the nature of the tyres, which are dealt with elsewhere. *See* TYRES. Now that freewheels are practically universal, it has become necessary to give much more attention to the subject of brakes. The old spoon brakes, which press directly on the tyre, were fairly satisfactory for solid tyred machines, or even for pneumatic tyres (except in case of a puncture), when the machine could also be checked by back pedalling; but in a freewheel machine, where back pedalling is impossible, greater brake power is required, and this is usually obtained by using brakes which act on the rims of both back and front wheels. The front wheel brake usually carries two blocks on a horseshoe-shaped clip, which is drawn upward by the brake levers, and presses on the lower (outer) surface of the rim at the top of the wheel. The back wheel brakes are generally made to act on the rim also, and are worked either by a series of levers or else by a flexible cable consisting of fine twisted steel wires running through a tube, as in the Bowden brake. By this plan, now largely employed in mechanics, power can be taken round corners by a (seemingly) slack wire without loss. In other cases the back wheel carries a drum about 5 or 6 in. in diameter, on which a band brake acts. This may be worked either from the handle bar or by mechanism connected by the crank shaft, so as to be brought into play when slight back pedalling is exerted. Other varieties of back pedalling brakes are also fitted; but as a general rule a good rim brake on the back wheel, in conjunction with the front, is more simple and also more reliable than these devices. *Tricycles:* The modern tricycle is almost invariably built with a front wheel fork and frame arranged as in the bicycle; the back fork is widened out to carry the long axle on which the two back wheels turn. The only important mechanical difference between the bicycle and tricycle, then, consists in the addition of what is termed "Differential Gear" (*q.v.*) placed in the centre of the axle. This enables one wheel to turn to a certain extent independently of the other when the machine is describing a curved path, *e.g.* turning a corner; but when the machine is going straight forward, the differential gear transmits the motion of the chain to both wheels equally. *See also* MOTOR CYCLES, SPEED GEARS, *and* TYRES.

Cyclometer. A small instrument for recording the distance run by a cycle or car by registering the number of revolutions of the wheels. The instrument contains a train of gear wheels, and a dial (or other indicator) usually graduated to read directly in miles.

Cyclone (*Meteorol.*) A system of winds in which the currents are circulating in a direction opposite to the hands of a watch; it is also an area of barometric depression, which becomes greater as the centre of the area is approached. In an ANTI-CYCLONE the motion and conditions of pressure are the opposite of those in a cyclone; the atmospheric pressure is greatest in the centre, and the air currents are in the direction of the hands of a watch. The whole system usually has a motion of translation.

Cylinder. (1) A geometrical solid produced by the revolution of a rectangle about one edge. (2) In engineering, a solid of this form, and also a vessel containing a cavity of the form of a cylinder, especially the cylinder of an engine. *See* STEAM ENGINE, *etc.*

—— (*Lace Manufac.*) That part of the Jacquard which presents each card in succession to the needles. It may be either square or hexagonal in shape, and of either wood or brass, each face or side having sufficient area to embrace the number of needles used, every needle being represented by a corresponding hole in each face of the cylinder. The holes in the card must be in perfect register with the holes in the cylinder, and the needles with both.

—— (*Watches*). The hollow cylinder on which is mounted the balance of the "horizontal" watch; it acts both as balance staff and pallets

Cylinder Bit. A long bit or drill with a cutting edge parallel to its axis, used for boring very accurate holes; a shallow cavity is first formed for entering the bit.

Cylinder Bore (*Eng.*) The internal diameter of the cylinder of an engine, etc.

Cylinder Cover (*Eng.*) Circular discs of cast iron, which may be flat, ribbed, or "dished" (*q.v.*), forming the ends or covers of the cylinder of an engine.

Cylinder Flanges (*Eng.*) Rings cast on a cylinder to which the covers are bolted.

Cylinder Lubricating Oil (*Eng.*) This must be a good lubricating oil, which will not corrode the cylinder nor gum, or form a deposit due to decomposition by the steam or other heated gas in the cylinder. Some mixture of mineral oils is usually superior to any animal oil.

Cylinder Lubricator (*Eng.*) A device for admitting oil to the cylinder for lubricating the piston. In gas engines a mechanical device is necessary for keeping up a constant supply of oil. In high-speed engines, which are often made single acting (*q.v.*), the crank is enclosed in a chamber containing oil. This communicates directly with the cylinder, so that when the crank revolves, it distributes the lubricant over the crank bearings, connecting rod, and the bore of the cylinder.

Cylinder Metal (*Eng.*) Iron which when polished has a low coefficient of friction, *i.e.* SLIPPERY IRON (*q.v.*): used for cylinders and any surface of cast iron where much friction occurs.

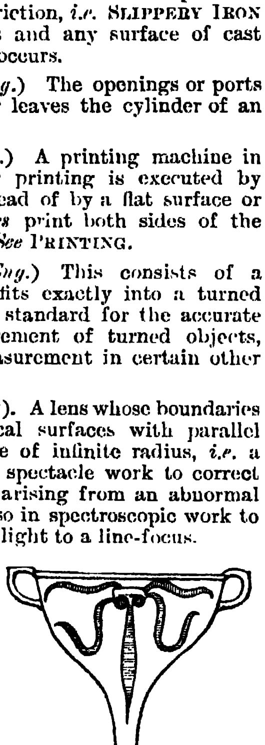
Cylinder Passages (*Eng.*) The openings or ports by which steam enters or leaves the cylinder of an engine.

Cylinder Press (*Typog.*) A printing machine in which the impression or printing is executed by means of a cylinder instead of by a flat surface or platen. *Double Cylinders* print both sides of the paper at one operation. *See* PRINTING.

Cylindrical Gauge (*Eng.*) This consists of a cylindrical block which fits exactly into a turned collar or ring; used as a standard for the accurate reproduction and measurement of turned objects, and as a standard of measurement in certain other cases.

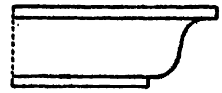
Cylindrical Lens (*Light*). A lens whose boundaries are portions of cylindrical surfaces with parallel axes; one surface may be of infinite radius, *i.e.* a plane. They are used in spectacle work to correct certain defects of vision arising from an abnormal form of the eye itself; also in spectroscopic work to convey a parallel beam of light to a line-focus.

Cylix, Kylix. A rather broad and shallow cup with two handles and a stem, used by the ancient Greeks: a Tazza.



CYLIX.

Cyma (*Architect.*) A compound moulding formed by the conjunction of a cavetto and an ovolo. It is also known as the OGEE. There are two varieties: the CYMA RECTA, in which the ovolo is below the cavetto; and the CYMA REVERSA, in which the cavetto is below the ovolo.



CYMA RECTA.

CYMA REVERSA.

Cymatium. A small moulding usually crowning another feature. Each of the following features is usually known as a cymatium: The upper mouldings, generally a fillet and a cyma reversa, of the abacus of a Roman Doric capital; the crowning mouldings of the architrave of the Ionic and Corinthian Orders; the moulding capping the horizontal cornice under the tympanum of a pediment. *See* COLUMN; ARCHITECTURE, ORDERS OF; IONIC; CORINTHIAN; *and* PEDIMENT.

Cymbal. *See* MUSICAL INSTRUMENTS, PERCUSSION (INDEFINITE SOUND).

Cymene (*Chem.*), $C_6H_4\begin{cases}{}^{(1)}CH_3 \\ {}^{(4)}CH(CH_3)_2\end{cases}$ (1 : 4), methyl isopropyl benzene. Liquid: boils at 175°: pleasant smell. It occurs in many essential oils, and especially in those of eucalyptus and caraway. It is obtained by heating camphor with phosphorus pentoxide or pentasulphide, also by heating turpentine with iodine.

Cypress. *See* WOODS.

D (*Music*). The second note in the scale of C.

Dabber (*Engrav., etc.*) A tool with a padded end, used to apply ink or other substance evenly to a surface—*e.g.* engraved plates, etc.

Da Capo (*Music*). From the beginning (of a movement). Abbreviated D.C.

Dacites (*Geol.*) Eruptive rocks of hemicrystalline structure, which consist essentially of soda lime felspars with ferromagnesian silicates, some free quartz, and a vitreous or lithoidal ground mass. They usually occur as intrusive rocks. They are the trappean representatives of the plutonic plagioclase granites or diorite granites, on the one hand, and of the quartz-andesites on the other.

Dado (*Architect*). (1) The die of a pedestal. (2) The wall space between the plinth and impost. (3) The lower part of the wall of an apartment when treated similarly to a continuous pedestal. *See* DIE, PEDESTAL, PODIUM, *and* ARCHITECTURE, ORDERS OF.

—— (*Dec., Join., etc.*) (1) Framing round a room, hall, or staircase, made to represent a continuous pedestal. Strictly, the space between the plinth and the capping, a flat surface extending usually to a height of between 3 and 4 ft. above the floor. (2) The painting, distempering, papering, etc., of the lower part of an interior wall when of a colour or material different from that of the upper part.

Dædals (*Archæol.*) Originally applied to archaic wooden effigies which represented deities, and were supposed to be carved by Dædalus, the constructor of the famous labyrinth at Crete.

Dag (*Arms*). A heavy pistol used in the sixteenth and seventeenth centuries.

Dagger (*Arms*). A short, pointed sword used at short quarters for killing or wounding an adversary by a thrust or stab. The early varieties, known as MISÉRICORDES, were worn by both military and civilians, and had no crossguard.

Dagges (*Cost.*) The cuttings or slashings round the edges of a garment. Sumptuary laws were passed to limit the same as early as 1188.

Daguerreotype. A photograph produced by the process introduced by Daguerre in 1839. A silver plate was used, which was rendered susceptible to the action of light by iodine; mercury vapour developed the picture.

Dais. (1) Formerly the elevated end of a hall whereon those of higher rank stood or sat; also the raised table in a hall at which distinguished persons sat. (2) The platform of a lecture hall. (3) The raised floor on which a pulpit stands.

Dalmatic (*Cost.*) (1) An ecclesiastical vestment. This garment was worn under the chasuble, but over the stole, tunic, and alb. The sleeves are wider and longer than those of the tunic. Generally made of white silk with purple stripes, but sometimes of other materials and colours. (2) A vestment worn by sovereigns at their coronation.

Dal Segno (*Music*). From the sign : marked :𝄋: Abbreviated D.S. Dal Segno is used when the repeat is not from the beginning.

Dalton's Atomic Theory (*Chem.*) *See* ATOMIC THEORY.

Dalton's Law (*Phys.*) If one or more liquids are introduced into a space of given volume, the amount of vapour given off by each depends only on the temperature, and is independent of any other gas or vapour present; and therefore the total pressure of the gases and vapours contained in the space is the sum of the separate pressures which each would exert if it were the only one present. The law does not hold good when the respective liquids and gases act chemically on one another.

Dam (*Civil Eng.*) (1) A barrier across a stream, etc., to keep back the water or to raise its level. (2) A watertight enclosure entirely surrounded by water; the water can be pumped out of the inside, and engineering or other operations carried on in the bed of the stream. Usually called a COFFER DAM.

—— (*Mining*). A partition used to keep out water or foul air from a working.

Damask (*Archæol.*) Originally the name for articles produced in Damascus, as DAMASK BLADE of a sword: subsequently used of a rich cloth or fabric of wool, silk, etc. elaborately figured or embroidered. *See* DAMASKENE.

—— (*Cotton Weaving*). A style of figured weaving in which the design is reversible and usually constructed on the warp and weft satin weave, so that all along floats are avoided and a well bound cloth is produced. Sometimes the name is used to distinguish a warp-figured cloth from a brocade.

—— (*Linen Manufac.*) In the linen trade, as in others, damask is a figured fabric, mostly used for table linens. It is usually called single or double damask, though there is not much difference, except that the former is the thinner and usually the coarser material, the double damask being a richer and better article, and showing out the pattern better. But for a cheap damask the good single one will wear better.

—— (*Silk Manufac.*) A figured silk fabric made from the combined action of mounture and satin harness, consisting usually of five or eight shafts. The mounture raises figure, whilst harness, if five shafts, raises one-fifth of warp threads and depresses another one-fifth for each pick. The result is satin ground with dull plain figure, the back of the work being exactly the reverse of the face. *See* HARNESS, MOUNTURE, SILK MANUFACTURE.

Damaskene, Damaskeen, *or* **Damascene** (*Archæol.*) As damask came to be applied to rich textile fabrics, damaskene was used for the embellishment or enrichment of metallic surfaces. *See* DAMASK (*Archæol.*)

Dam Board (*Textiles*). *See* DIAPER.

Dammar (*Botany*). A conifer, *Agathis Dammara* (order, *Coniferæ*), closely allied to the Kauri gum tree, yielding the transparent resin Dammar, used in varnish making.

Damp (*Mining*). Foul air, *i.e.* air containing carbon dioxide, etc. *See also* CHOKE DAMP *and* AFTER DAMP.

Damper (*Build., Eng., etc.*) An iron shutter fitted in a flue to regulate the draught.

Damper Weight (*Eng.*) A counterpoise weight attached to a flue damper by a chain passing over a pulley to balance its weight and render it easy to raise or lower.

Damping (*Moulding*). Moistening foundry sand to cause it to be more coherent.

—— (*Phys.*) The checking of motion, particularly of vibratory motion, by the friction of the medium in which the moving body is placed, or by other retarding forces. For example, the amplitude of the vibrations of a sounding body gets less and less, and the sound dies away if the body is left to itself; and similarly a pendulum slowly comes to rest when set vibrating in the air.

Damping Down (*Eng.*) Putting small and damp coal on a fire to cause it to burn very slowly, and hence to keep alight a long time.

Damping Rolls (*Paper Manufac.*) Metal cylinders of small diameter used for damping paper.

Dam Plate (*Met.*) An iron support of the DAM STONE (*q.v.*) in a blast furnace.

Damp Proof Course (*Build.*) A frequent cause of dampness in houses is the rising of moisture in brickwork due to capillary attraction. In order to prevent this, layers of waterproof materials, termed DAMP PROOF COURSES, are constructed. These are placed just above the ground level and across the thickness of the wall; they may be constructed of stoneware slabs with holes for ventilation, sheet lead, or layers of asphalt, tarred jute, or slates floated in cement.

Dam Stone (*Met.*) A stone which prevents the molten iron from flowing out at the base of a blast furnace.

Dan (*Mining*). A small sledge used for dragging weights.

Dancette (*Her.*) Lines dividing a shield similar to indented lines, but larger and deeper. The indentations never exceed three in number.

Dancing Steps (*Carp.*) *See* BALANCED STEPS.

Dandy Roll (*Paper Manufac.*) A skeleton roll covered with wire cloth and carrying patterns or names for the production of "watermarks."

Dangerous Infectious Diseases (*Hygiene*). Included in this expression, as defined by the Public Health Statutes, are the following diseases, namely: smallpox, cholera, diphtheria, membranous croup,

erysipelas, scarlatina or scarlet fever, the fevers known by any of the following names: typhus, typhoid, enteric, relapsing, continued, or puerperal. In addition, the sanitary authority of any district and the County Council in London are empowered to extend notification to diseases other than those set out. It is very important that the occupiers of houses should understand clearly the duties cast on them in regard to the notification of these diseases. Where an inmate of any house within the district of a sanitary authority is suffering from an "infectious disease" (as above), the head of the family to which such inmate belongs, and in his default the nearest relatives of the patient present in the house or being in attendance on the patient, and in default of such relatives every person in charge of or in attendance on the patient, and in default of any such person the master of the house shall, as soon as he becomes aware that the patient is suffering from an infectious disease as above, send notice thereof to the medical officer of health of the district. It must be noticed that the medical practitioner attending on or called in to visit the patient is also made responsible in regard to notifying the medical officer of health. Failure to comply with the Acts in this respect renders the person who is required to send a notice or certificate to the sanitary authority liable to a fine.

Daniell's Cell (*Elect.*) *See* CELLS, PRIMARY.

Daniell's Hygrometer (*Phys., etc.*) *See* HYGROMETERS.

Dark Lines in the Spectrum (*Phys.*) *See* SPECTRUM ANALYSIS.

Darkroom (*Photo.*) A room lit only by light which will not affect a photographic plate, *i.e.* orange or red light of low intensity. A darkroom should be well ventilated and fitted with a table, sink, shelves, and other conveniences for development.

Darkroom Lamp (*Photo.*) A lamp surrounded by an orange or ruby shade, or an electric lamp immersed in a solution of quinine, thus giving non-actinic light.

Darley Dale Stone. *See* BUILDING STONES.

D'Arsonnal Galvanometer (*Elect.*) *See* GALVANOMETER.

Dart (*Arms*). A sharp-pointed weapon thrown by the hand: sometimes used as an arrow.

Dartmoor Granite. *See* BUILDING STONES.

Dash (*Music*). *See* STACCATO.

Dash Piston (*Eng.*) The piston of a DASH POT (*q.v.*)

Dash Plate (*Eng.*) A baffle plate (*q.v.*), which prevents the water in a ship's boiler from flowing suddenly away from the plates of the firebox when the ship rolls.

Dash Pot (*Eng.*) A device for preventing sudden motion of some part of a piece of mechanism by utilising the viscosity or inertia of a fluid. A simple form consists of a small vessel of liquid in which a piston moves loosely. A very small force, steadily applied, is sufficient to cause motion of the piston; but considerable resistance is offered to any sudden movement. Another form consists of a cylinder with an air-tight piston. As the latter moves, air can enter or leave the cylinder through a very small opening. A sudden movement is thus prevented by the change of pressure which is produced inside the cylinder. It is often applied to form an air cushion to reduce the shock or throw in a reciprocating motion; *e.g.* the bed of a printing press at the end of its travel.

Dash Wheel (*Chem. Eng.*) A washing or rinsing wheel used in washing textiles.

Date (*Botany*). The fruits of the date palm, *Phœnix dactylifera* (order, *Palmæ*), form the principal food of the Arabs of Northern Africa. The leaf stalks are used for cordage, mats, and baskets.

Datholite (*Min.*) A basic calcium and boron orthosilicate, $H_2O \cdot 2CaO \cdot B_2O_3 \cdot 2SiO_2$. Monosymmetric: occurring in glassy crystals, usually in veins in basic volcanic rocks. It sometimes alters to chalcedony, giving the pseudomorphous HAYTORITE. From Norway, Scotland, and the United States.

Datum Level *or* **Line** (*Surveying*). A line or level from which heights are calculated and measured. *See also* CONTOUR.

Daturine (*Chem.*) Another name for HYOSCYAMINE (*q.v.*)

Daub (*Paint.*) To paint carelessly, without taste or feeling, thus producing an inharmonious whole very offensive to the artistic eye.

Daucus (*Botany*). *Daucus carota* (order, *Umbelliferæ*). The well-known vegetable, the carrot, is a garden variety of the wild form. A medicinal volatile oil is extracted from the seeds in India.

Day (*Mining*). Parts of the workings near the surface where light can reach.

Daylight Loading (*Photo.*) A method of charging a hand camera with films by having the latter wound on a spool in contact with a strip of black paper. The latter is longer than the roll of film, and forms several turns round the outside of the spool. The end of the black paper is first detached and made fast to a roller in the camera. The latter is then closed and the roller turned, drawing the black paper along until the film attached to it is in the position to receive the image. The method has been worked out with great simplicity and ingenuity by the Kodak Company. Flat films are also made up into sets, like a pack of cards, and can be placed in cameras fitted with a suitable slide without the use of a darkroom.

Day Roll (*Photo.*) A name applied to the spool used in daylight loading of cameras. The sensitive emulsion is on a flexible film of length sufficient for a number of exposures (commonly twelve). The film is laid face upward on a strip of opaque black paper, longer than itself, and the two are wound together on a spool. The free end of the film is made fast to the paper, and the latter forms several turns round the outside of the spool to exclude light. *See* DAYLIGHT LOADING.

Day, Sidereal (*Astron.*) The period of a complete revolution of the stars, relative to the meridian. Its length is about four minutes less than the ordinary day. It is absolutely constant in duration.

"Day" Theory (*Music*). That advanced by Alfred Day, M.D. Important points: All chords derived from three roots, *viz.* Tonic, Dominant, and Supertonic. The building up of chords by 3rds to 9ths, 11ths, and 13ths. The division of Diatonic and Chromatic styles. The "Added 6th" is the 3rd inversion of the Dominant 11th. The "Sharpened 5th" is the Dominant 13th resolved upwards. The "Augmented 6th" derived from Dominant and Supertonic roots.

Day Work (*Various Trades*). Work paid for by the day instead of by the piece.

Deacon's Process (*Chem.*) A method of preparing chlorine on the large scale for the preparation of bleaching powder (*q.v.*) or any other purpose. Hydrochloric acid gas and air are passed over a heated porous surface (broken bricks) impregnated with copper sulphate. Excess of hydrochloric acid is removed by water, and for making bleaching powder the gas must be dried by passing through sulphuric acid.

Dead (*Eng., Build., etc.*) A term applied to materials of many kinds when they have lost some of their important or characteristic properties.

Dead Axle (*Eng.*) (1) An axle which does not rotate; (2) one which does not communicate motion to wheels, etc., but simply turns with them.

Dead Beat (*Clocks*). The "Graham" clock escapement in which the escape wheel, as soon as the drop has taken place, remains absolutely at rest ("dead"), thus distinguishing it from the older form of "recoil" escapement.

Dead Blow (*Eng.*) A blow struck without any spring or rebound.

Dead Burnt. A term applied to lime which has become vitrified by fusion of calcium silicate in the limekiln. It prevents proper slaking.

Dead Centre Lathe (*Eng., etc.*) A small lathe in which work is supported between two fixed or dead centres; motion is communicated to the work by a pulley or some other device fixed to it. Much used by watch and clock makers.

Dead Centres (*Eng.*) (1) Supporting points of a lathe, etc., which do not rotate. The back centre of a common lathe is often called a dead centre. *See also* DEAD CENTRE LATHE. (2) Also applied to the DEAD POINTS (*q.v.*) of an engine.

Dead, Disposal of the. *See* SANITATION.

Dead Eye (*Eng.*) A bearing in which the shaft runs in a hole bored through a single piece of metal, instead of in split BRASSES (*q.v.*)

Dead Ground (*Mining*). Parts of the vein or lode without ore, composed of GANGUE (*q.v.*)

Dead Head (*Eng.*) (1) The DEAD CENTRE of a lathe (*q.v.*) (2) A mass of metal filling a cavity at the head or top of a runner or pouring hole in a mould. The dead head is connected with the casting by the core of metal filling the hole or runner. The head and connecting metal are broken off when the casting is cold.

Dead Load Safety Valve (*Eng.*) A SAFETY VALVE (*q.v.*) kept down by a simple weight on the top, without any lever being used, as in the ordinary form of safety valve.

Dead Melting (*Foundry*). Heating metal till it becomes perfectly fluid, *i.e.* to a temperature considerably above its melting point.

Dead Plate (*Eng.*) A plate inside a firebox, on which fresh fuel is first placed, in order to become heated before reaching the fire proper.

Dead Point (*Eng.*) The position of a crank when it cannot be turned by the motion of the piston rod—*i.e.* when the crank and piston rod lie in the same straight line. A single cylinder engine cannot start from the dead point, and the crank must be slightly turned before steam is admitted. The dead points are sometimes also termed DEAD CENTRES.

Deads (*Mining*). Rubbish not containing ore.

Dead Shore (*Carp.*) Timber placed in a vertical position to support a load which acts downward only, *i.e.* without any outward thrust.

Dead Smooth File (*Eng.*) The very finest file cut; it has eighty or ninety teeth per inch.

Dead Turns (*Elect. Eng.*) The electromotive force produced in a dynamo is generally represented as proportional to the number of revolutions per second. *See* DYNAMO. But as the speed is increased the E.M.F. does not increase in the same proportion, owing to internal effects; so that the actual number of revolutions is greater than the number theoretically required to produce the E.M.F. obtained, and the extra revolutions are termed DEAD TURNS. For example, if a dynamo give 100 volts at 500 revolutions, it should give 150 volts at 750 revolutions if the law of proportionality held good. It will probably be found that more revolutions are necessary to give the 150 volts; if the number be 800 there are 50 dead turns.

Dead Wall (*Build.*) A BLANK WALL, one not pierced by doors or windows.

Dead Water (*Eng.*) Water which does not come into contact with the effective heating surface of a boiler. The best types of boiler reduce this water to a minimum amount.

Dead Weight *or* **Load** (*Eng.*) A load which is constant in position and amount; the opposite of a LIVE LOAD (*q.v.*)

Dead Weight Safety Valve (*Eng.*) *See* DEAD LOAD SAFETY VALVE.

Deal. A general name for certain coniferous woods. *See* WOODS.

Deal Frame (*Carp., etc.*) A machine saw used for cutting DEALS (*q.v.*) into thinner boards; it usually carries several parallel saws of the reciprocating type

Deals (*Carp., etc.*) Sawn wood (deal) of size 9 in. × 3 in. or 12 in. × 3 in.

Dean (*Mining*). The extreme end of a working.

Death Rate (*Hygiene*). By a death rate is understood the ratio between the deaths and population. The formula for calculating this rate is:

$$\frac{\text{Number of deaths} \times 1{,}000}{\text{Population}}$$

Thus, supposing a town has a population of 85,000, and the number of deaths during the year was 1,125, then $\frac{1{,}125 \times 1{,}000}{85{,}000} = 13{\cdot}23$ per 1,000. To obtain a death rate for any one week, divide the estimated population by 52·17747, the result giving the weekly population. Thus $\frac{85{,}000}{52{\cdot}17747} = 1{,}629$. Supposing there are twenty-one deaths during one week, then the death rate per thousand is : $\frac{21 \times 1{,}000}{1{,}629} = 12{\cdot}89$.

Debruised (*Her.*) An expression used when an ordinary is placed upon a charge. But when the ordinary is placed upon another ordinary, the term "over all" or "surmounted by" takes its place: "debruised by" is not then used.

Decadence. A falling off from a better style. In art the term is used to denote the period after Raphael and Michael Angelo.

Decametre. *See* WEIGHTS AND MEASURES.

Decani (*Music*). That side of the choir on which the dean (decanus) sits. The opposite side to cantoris. The right side looking east.

Decarburisation (*Met.*) Removal of carbon from cast iron by the PUDDLING PROCESS (*q.v.*) or the BESSEMER PROCESS (*q.v.*)

Decastyle (*Architect.*) A term applied to a temple which has ten columns in the front row. *See* DISTYLE, TETRASTYLE, HEXASTYLE, *and* OCTASTYLE.

Deciduous (*Biology*). The term applied to those organs or parts which are shed periodically by a plant or animal; *e.g.* the leaves of the oak, ash, and the horns of most varieties of deer are deciduous.

Decimal. A fraction whose denominator is ten or a power of ten. It is written without the denominator, the numerator being preceded by a dot, the DECIMAL POINT, written on the left-hand side of the figure: thus $155{\cdot}65 = 155\frac{65}{100}$.

Decimal Gauge (*Eng., etc.*) A gauge divided into decimals of an inch, instead of the ordinary fractions, $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, etc.

Decimal Point. *See* DECIMAL.

Decimal Threads *or* **Pitches.** *See* SCREW THREADS.

Decimetre. *See* WEIGHTS AND MEASURES.

Decimo Sexto (*Print.*) The size of a sheet of paper after being folded to form sixteen leaves. Usually called SIXTEENMO and written 16mo.

Deciso (*Music*). Decided.

Deck Crane. A crane fixed on the deck of a ship for loading purposes; frequently driven by a steam winch supplied from the main boilers.

Deckle (*Paper Manufac.*) (1) A movable wooden frame which fits over a wire mould, used in the manufacture of paper by hand. (2) The rough or irregular edge of handmade paper. The two uneven edges of a Bank of England note are examples.

Deckle Straps (*Paper Manufac.*) Endless rubber bands which run on the machine wire to keep the wet pulp in its proper position, and regulate the width of the paper.

Declination (*Astron.*) The angular distance of a star above the horizon, measured along a vertical circle. Abbreviated to DECL. The vertical great circle through the star and the celestial pole is termed the DECLINATION CIRCLE.

Declination Circle (*Astron.*) *See* DECLINATION.

Declination, Magnetic. The horizontal angle between the axis of a freely suspended magnetic needle and the true geographical meridian. This varies at different points on the earth's surface, and is also slowly but constantly changing at any given point.

Decomposition of Light. *See* SPECTRUM, COLOUR, *etc.*

Decorated (*Architect.*) The name given to one of the periods of Gothic architecture. Architecture in England can be divided into the following styles, but it must be noted that the transition from one style to another was very gradual.

	A.D.
ANGLO-SAXON	449—1066.
NORMAN .	1066—1175 (Early, 1066—1125. Late, 1125—1175).
TRANSITION .	1175—1189.
EARLY ENGLISH	1189—1307.
DECORATED .	1307—1377.
PERPENDICULAR	1377—1547.

The following are some of the characteristics of the Decorated style: (1) The extensive use of scroll and wave mouldings. Strong contrasts of light and shade common in Early English mouldings are avoided. (2) The ball flower. (3) Geometrical, Reticulated, Flowing, and Flamboyant window tracery. (4) Foliage less conventional than in the other periods of Gothic architecture. (5) Detached shafts as used in Early English pillars are abandoned. *See* CURVILINEAR *and* FLAMBOYANT.

Decorticating. (1) A process carried out by cutting or pulverising machines which assist the separation of the husks and linters from the oily kernels of cotton seed, linseed, or castor beans prior to pressing. Special machines are made for arachis and cocoanuts. (2) A similar result is obtained chemically by acting on cotton seed with a mixture of nitrous anhydride and sulphur dioxide gases in the presence of enough air to reoxidise the reduced nitrogen compounds. A few seconds suffice to destroy the structure of the husks, which crumble to a fine powder with the slightest friction.

Decrescendo (*Music*). Decreasing in loudness. Abbreviation, DECRES or >.

Deep Sea Deposits (*Geol.*) Strata which have been formed at great depths below the surface of the ocean. These are primarily divisible into (1) TERRIGENOUS, which consist of materials mostly derived from the waste of adjacent lands, and (2) THALASSIC, which are due more or less directly to organic or organico-chemical causes. To the former belong blue muds, coral mud, glauconite, and some others; to the latter, foraminiferal ooze, diatom ooze, radiolarian ooze, and the red clays, which occur with the last named deposit. These are partly of chemical origin.

Deep Well Water (*Hygiene*). Deep wells supply many towns with water. Borings are made to a considerable depth, penetrating the upper impermeable strata, until the water-bearing stratum is reached. Water obtained from this source is usually hard, but very palatable and wholesome. *See* ARTESIAN WELLS.

Deer (*Zoology*). A family (*Cervidæ*) of the great mammalian group of *Ungulates*. They are very widely distributed, being found in nearly every part of the world. The horns are confined to the male, and are shed annually, except in the case of the Reindeer. *See* HORN.

Deflection (*Eng., Build.*) Bending: deviation from an original position or direction, *e.g.* the sagging of a beam or girder at the centre when supported at both ends. *See* BEAMS.

—— (*Met.*) A test for steel rails, varied according to section and weight. Double headed 70 lb. to yard rails, supported between centres 3 ft. 6 in. apart, must not show (1) more than 3 in. deflection after two blows in the centre from a ton weight falling 18 ft.; (2) or $\frac{5}{8}$ in. deflection under a dead weight of 28 tons.

Deflector (*Eng.*) A general term for a plate or other object used to direct a stream of gas or a liquid in a particular direction: frequently used in furnaces and fireboxes to direct the hot gases along a certain path.

Deformation (*Phys., etc.*) A general term signifying an alteration in the shape of a body, whether permanent or not.

Degelatinising. The process of extracting gelatine or glue from bones. This may be done either wholly or partially: if the former, the residue is used wholly for manurial purposes (*see* MANURE); if the latter, the residue of the bones is calcined to form animal charcoal.

Degras. A fat or grease obtained during the manufacture of leather, particularly chamois leather. It is also obtained as a byproduct in various other trades. Degras is often made as a regular commercial article by oiling hides with cod oil, fermenting, fulling, and treating with potash. Degras in England is more commonly called SOD OIL, which is, strictly, the oil from curried leather in general, Degras being obtained from chamois leather only. Artificial Degras is made by adding tallow to cod oil (and sometimes red oil and wool grease), and incorporating with a neutral soap.

Degreasing. The process of extracting fat or grease from wool and bones by means of benzene or other solvent.

Degree. *See* WEIGHTS AND MEASURES.

—— (*Heat*). The unit in which difference of temperature is measured. *See* CENTIGRADE, FAHRENHEIT, *etc.*

—— (*Music*). Each step (line or space) of the stave.

Degrees of Freedom (*Phys.*) A body which is perfectly free has six possible varieties of motion, three motions of translation parallel to three axes which are mutually at right angles, and three motions of rotation about axes parallel to the same three axes of reference. These six varieties of motion are called the "Degrees of Freedom" of the body, and any one or more may be destroyed by introducing a suitable constraint. Thus a cube lying on a plane surface has two motions of translation and one of rotation, *i.e.* three degrees of freedom. A ring smoothly fitting a round rod has two degrees of freedom, one of translation along the rod and one of rotation round it; and a square ring or frame which fits exactly on a square rod has one degree of freedom, a motion of translation only.

—— (*Chem.*) *See* PHASE RULE.

Dehiscent Fruits (*Botany*). Fruits which open naturally to set free their seeds. They are usually called CAPSULES.

Del *or* **Delt** (*Art*). Short for the Latin word *delineavit, i.e.* has drawn. On an engraving, etc., it follows the name of the author or designer of the original drawing from which the reproduction has been made.

Dele (*Typog.*) *See* DELETE.

Delete (*Typog.*) To expunge, blot out, erase, or omit. Indicated in proofs thus, δ. *See also* PROOF CORRECTIONS.

Delft. The term Delft is now rather indiscriminately applied to all Faience with blue decoration upon a white ground; true Delft-Faience was first made at Delft, near Rotterdam, in Holland, about the beginning of the seventeenth century; it consisted of a yellowish earthenware paste covered with an opaque stanniferous glaze, the blue and other coloured decorations being superimposed. Large quantities of blue and white wares are still made at Delft.

Delicato (*Music*). With delicacy.

Deliming (*Leather Manufac.*) Removal of the lime from the skin previous to tanning. *See* LEATHER MANUFACTURE.

Deliquescence (*Chem.*) Certain solid substances have the power of absorbing moisture from the air and forming a solution therewith. Such substances are said to be deliquescent. Examples are calcium chloride, caustic soda and potash, ferric chloride.

Delivery (*Eng.*) The discharge of water, etc., by a pump. RATE OF DELIVERY is the usual expression for the amount of fluid pumped per minute.

—— (*Foundry*). The manner in which a pattern leaves the mould.

Delivery Pipe (*Eng.*) The pipe by which water flows from a pump.

Delta (*Geol.*) Fan-shaped areas composed of mud, sand, silt, gravel, etc., brought together by the action of rivers, and dropped at the parts where their velocity, and therefore their transporting power, is checked. Deltas usually occur at the junction of rivers and the waters of lakes or those of the sea; but they may also be formed at the foot of a slope upon the land.

Demi Brassards (*Armour*). Strips of metal which protected only half of the arm.

Demi Lion Rampant (*Her.*) A lion rampant cut off or couped midway, the upper part only appearing, including the forepaws and the tip of the tail.

Demisemiquaver (*Music*). *See* NOTES.

Demivol (*Her.*) One wing only displayed as a charge on a shield. It should be described as either dexter or sinister.

Demy (*Papers*). A size of paper. Printing demy measures $22\frac{1}{2} \times 17\frac{1}{2}$ in.; writing demy, $20 \times 15\frac{1}{2}$ in., and drawing demy, 22×17 in.

Den (*Chem. Eng.*) The reaction pit or chamber for the manufacture of superphosphates. Placed immediately under the mixers.

Dendritic Markings (*Geol.*) Accumulations of mineral matter, usually one of the hydrated oxides of manganese, less frequently hydrated oxide of iron, which have assumed a mosslike or treelike form in the course of their growth from aqueous solutions. Their resemblance to organic forms is purely accidental.

Denim (*Cotton Weaving*). A very heavy-warp twilled cloth composed of hard twisted warp and usually coarse cop weft. The warp is mostly composed of one colour.

Density (*Photo.*) A term used to describe the strength and vigour of a negative. A dense negative has the dark portions very strongly defined, and a gradual gradation to the most transparent parts; such a negative gives a good print, full of detail.

—— (*Phys., etc.*) The quantity of material or matter contained in unit volume. The specification of density, unlike specific gravity (*q.v.*), always requires the use of two units—one of volume, the other of mass. For example, density may be given in grams per cubic centimetre, grams per litre, pounds per cubic foot, tons per cubic yard, etc.

Density of Gases (*Phys., Chem.*) Conveniently quoted in grams per litre: the expression generally used in chemical books is really the specific density in terms of hydrogen: thus if the density of a gas is said to be 16, it is sixteen times as heavy as the same volume of hydrogen at the same pressure and temperature.

Density of Petrol (*Motor Cars*). *See* PETROL.

Density of Water (*Phys., etc.*) *See* WATER.

Dent (*Textile Manufac.*) A split or space in the reed or sley (*q.v.*)

Dentelle (*Binding*). A style of finishing (with very fine tools) delicate gilt designs to resemble lacework.

—— (*Lace Manufac.*) The French term for lace. A lace that is finished off with a toothed edge.

Denticulated Bed Mould (*Architect.*) A bed mould enriched with DENTILS (*q.v.*)

Dentils (*Architect.*) An ornament originally used in the bed-mouldings of the Ionic and Corinthian cornices. It consists of a series of rectangular blocks, the height of each block being about twice its width, and the width of the spaces between the blocks about one-third their height. *See* INTERDENTILS.

Dentine (*Zoology*). The bonelike substance of a tooth. It is covered by a very hard secretion—the ENAMEL.

Denudation (*Geol.*) A general term expressive of the results of various natural agencies in wasting or wearing away exposed surfaces of rocks. SUB-AËRIAL DENUDATION is that which is effected by rain, rivers, frost, and chemical action. GLACIAL DENUDATION is that arising from the erosive influence of stones carried forward by ice moving in contact with the surface of rocks. MARINE DENUDATION is that wrought by the action of the sea. The two chief agents which supply the motive power are solar energy on the one hand, and gravitation on the other.

——, **Rate of** (*Geol.*) Various estimates have been made, chiefly by Lyell, Croll, and Tylor, of the rate at which the materials composing the land are being stripped off and the level reduced to that of the sea. This is arrived at by estimating the quantity of material transported in suspension, in solution, and otherwise carried seaward per annum by some river, measuring the area drained by that river, and thus arriving at the total quantity removed from the whole surface of its basin in the period chosen. The rate varies within wide limits; but an average is usually taken at about one foot in three thousand years.

Deodar. *See* WOODS.

Deodorant (*Hygiene*). A substance which, by the oxidation of the products of decomposition, destroys or masks offensive odours. Among the common deodorants are charcoal, chloride of lime, dry earth.

Deoxidation (*Met.*) The REDUCTION (*q.v.*) of ores during smelting or by some preliminary process such as ROASTING (*q.v.*)

Dephlegmator (*Chem. Eng.*) A still-head or rectifying apparatus used in distilling spirits and other products with low boiling points. *See* FRACTIONAL DISTILLATION.

Dephosphorisation (*Met.*) Removal of phosphorus from iron by the BASIC PROCESS (*q.v.*)

Depickling (*Leather Manufac.*) Skins which are pickled with salt or acid for transport must be depickled before tanning. For this purpose whiting, salt, and other similar compounds are used.

Deposit. The term applied to the metallic coating obtained in electroplating.

Deposit (*Eng.*) Matter collected on boiler plates; also called INCRUSTATION (*q.v.*)

Deposition (*Geol.*) The correlative of denudation. Materials removed from areas exposed to the action of the various natural agents of waste are moved by running water, and are, sooner or later, left again in the solid form. The chief agents concerned in both processes are solar energy and gravitation, operating by means of water. As in the case of denudation, the rate of deposition varies within very wide limits. Deposition is the usual concomitant of depression of the surface, and is, of course, also dependent upon denudation.

Depression (*Meteorol.*) An area over which the barometric pressure is low, gradually diminishing from the edge of the area towards the centre.

Depression of Land (*Geol.*) Changes of level of the land, generally effected by undulatory movements of the Earth's crust, appear to have affected each part of the surface at one time or another. The wave-like movement slowly progresses from one part to another, and the upward phase, which gives rise to elevation of the land, is followed by the opposite or downward phase of the terrestrial undulation, whereby depression is produced. Deposition of sedimentary materials usually accompanies depression of the land.

Depression of the Freezing Point (*Heat*). *See* FREEZING POINT.

Depth (*Paint.*) The suggestion of subtle variety produced by sensitive management of gradations of tone. It is the converse of superficiality of tone quality, and is one of the sources of the pictorial mystery which gives to inspired works of art their special persuasiveness. The word is also used in association, *e.g.* depth of tone, to define the particular quality of a picture which is pitched in a low key.

Depth of Focus (*Photo.*) The power of a lens to produce a sharp image of objects which are at varying distances from the camera. It depends on the relation of the diameter of the STOP (*q.v.*) to the focal length of the lens.

Derby China. Porcelain was first made in Derby about 1750. The Derby Porcelain Works, however, were not established until 1756, under William Duesbury. It was continued by him, his son, and his grandson until the year 1815, when the business was sold to Robert Bloor, who carried it on until 1846, when it was finally closed. The most beautiful wares were produced at Derby at the end of the eighteenth century. Under Bloor they degenerated both in refinement and taste. The best period of Derby china was from about 1775 to 1800, during which time painting and gilding were brought to a high state of perfection. For MARKS, *see under* POTTERY AND PORCELAIN.

Derby Float. (*Plastering*). A long piece of board with a handle at each end. Used for "floating" large surfaces. *See also* FLOAT.

Derby Red (*Dec.*) A scarlet red pigment of good covering and staining power, sometimes used as a substitute for vermilion (*q.v.*) It is a basic chromate of lead, and is crystalline in structure. Called also CHINESE RED, CHROME RED, and AMERICAN VERMILION.

Derbyshire Spar (*Min.*) A popular synonym for FLUORSPAR (*q.v.*)

Derivative Rocks (*Geol.*) Are those which are composed of materials derived from some pre-existent rocks. It is usual to regard all massive eruptive rocks (as distinguished from those of pyroclastic origin) as being original. Conglomerates, sandstones, shales, and clays are good examples of derivative rocks. Limestones, coal seams, and several other types of rock may be regarded as either original or derivative.

Derived Fossils (*Geol.*) It frequently happens that, when a fossiliferous rock is undergoing waste at the surface, the fossils included in it are liberated, and are subsequently rearranged along with other materials in rocks of later date. Such fossils need to be distinguished from those which actually lived during the period when their matrix was laid down, and the above name is conveniently applied to them in consequence.

Derived Units (*Phys.*) All others than the fundamental units of time, length, and mass, *e.g.* the units of space, acceleration, force, etc.

Dermal Denticles (*Zoology*). The small toothlike scales on the skin of the sharks and dogfishes. These give the shagreen character to these fish skins.

Dermis (*Zoology*). The sub-epidermal layer of the skin, consisting of connective tissue containing capillaries and nerves.

Derrick. The pyramidical frame which carries the boring apparatus used in drilling oil wells. Sometimes called an oil "rig," which really comprises the complete drilling outfit. The frames are mostly open (like a colliery headgear) in American oil fields, and boarded-in on European fields.

—— (*Build.*) A mast kept in position by guy ropes, and having a pulley fixed to it at the top, with a rope passing through to a windlass. Used for hoisting trusses, etc.

—— (*Eng.*) A form of crane (*q.v.*) with a hinged jib, which can be set at various angles: also applied to a system of poles used to support hoisting gear.

Derrick Barrel (*Eng.*) An auxiliary chain barrel in a crane on which the DERRICK CHAIN (*q.v.*) is coiled.

Derrick Chain (*Eng.*) The chain by which a hinged jib is raised or lowered. *See* CRANE.

Descending Letters (*Typog.*) Those letters having descending strokes, viz. *g*, *j*, *p*, *q*, and *y*.

Descriptive Astronomy. The science dealing with the motion and distances of the heavenly bodies.

Descroizilles Degrees. The French soapmakers' *titre* or standard for soda ash. The strength is expressed in terms of pure sulphuric acid (=49) neutralised by 100 parts of soda ash. The German standard is in terms of Na_2CO_3 (=53). The English standard (sometimes called GAY LUSSAC DEGREES) is the percentage of Na_2O (=31), or real alkali, which is generally displacing the old trade degree based on 64 instead of 62 as the molecular weight of Na_2O. Therefore pure soda ash = 31° English, 92·45° Descroizilles, and 100° German.

Desert (*Geol.*, *etc.*) Any part of the surface of the land where the conditions have long been unsuitable for the growth of vegetation. The usual meaning attached to the word, however, implies that deserts are only due to a small rainfall (generally under 10 in. per annum), which occurs at intervals too irregular to permit of the growth of any vegetation except such as is specially adapted to the conditions. They are not confined to the hotter regions of the globe; *e.g.* areas of drifting volcanic sand in Iceland form deserts.

Desiccating (*Carp.*, *etc.*) Artificial drying of timber by heat.

Desiccator (*Chem.*) Of various shapes, but consisting essentially of a closed vessel with a receptacle for calcium chloride, strong sulphuric acid, or other water absorbing substance, and a shelf to carry the article to be kept dry.

Design. Design in its relation to the fine and applied arts implies invention—the creation of something which had no previous existence in that particular form, and which is therefore original and new. But it is doubtful whether originality in its completest sense exists. It is not given to us to imagine anything beyond the limits of human experience, so that our creations are little more than recollections and modifications of things or forms already existing in nature. The fabulous beings imagined by the ancients—the centaur, the satyr, the cyclops, the mermaid are cases in point; they are not inventions, but combinations of existing material. In the domain of the fine arts, for the production of a picture, a statue, or a cathedral, design plays an important part, since the proportions, the proper balancing of units, must be carefully considered. It is, however, in the so-called lesser arts or crafts that design in the more usual acceptation of the term is brought into play. This is called APPLIED DESIGN. It consists of the application of beautiful forms and colours to a particular object or purpose, such as a stained glass window, a wallpaper, a piece of jewellery, or to the various articles of daily use. The application of design has been practised during all ages, from the time of primeval man: by the cave dwellers, who traced designs and fancies upon bones, shells, and the walls of their caves; by the savage tribes, who decorated their canoes, their weapons of warfare, and even their own persons. The fundamental laws governing ornamental design, such as radiation, tangential junction, symmetry, balance, etc., are direct expressions of natural principles or facts: that of radiation in the sun's rays, the digits of the human hand, in starfish, etc.; that of tangential junction in plant and tree growth, the springing of branches from a parent stem. Even the various ornamental motifs, *e.g.* the circle, may be seen exemplified in the sun, the full moon, and the contours of various flowers, the spiral in serpents, in the convolutions of shells, and the tresses of human hair. Applied design, together with the rest of the fine arts, has always reached its highest development at the time of a nation's fullest growth, and to trace the history of a nation's art is to follow the growth of its civilisation. In the case of Egypt, the Cradle of the Arts, their civilisation had already reached its highest development at the time when the story of her existing monuments begin, all

authorities agreeing that the further we go back in Egyptian history, as told by her monuments, the finer the art. The long story of Egyptian art is therefore one of gradual and slow, but no less sure, decline, but a decline from a very high level of past attainment. From Egypt the centre of civilisation was transferred to Athens, and then to Rome, and from thence to Constantinople, the seat of the Byzantine Empire, which lasted practically to the birth of the mediæval period in the time of Charlemagne. In the thirteenth century architecture, which is properly the foundation of all the arts of design, was at its zenith. The so-called RENAISSANCE was a return to classic ideals. The GOTHIC style was slow to take root in Italy; it bloomed brilliantly, but only for a comparatively short season. The break up of the Renaissance came very suddenly, about the close of the sixteenth century; and from that time all the decorative arts slowly declined, until they reached their lowest ebb perhaps about the middle of the nineteenth century. From that time matters have gradually improved. In 1851 came the Great Exhibition, which, whatever its subsequent effect upon the decorative art of the country, at any rate showed us exactly where we were. It certainly was the means of opening our eyes to the wealth of design and splendour of colour of the art productions of our great dependency, India. During the latter half of the nineteenth century the most considerable figure in the decorative art world is unquestionably that of William Morris. It is not too much to say that it is mainly to the influence and inspiration of Morris that we owe the improvement which has taken place in our furniture, wallpapers, textiles, stained glass, embroidery, and latterly, since the founding of the Kelmscott Press, the decoration and printing of books. The art of William Morris was founded upon a study of the work of the twelfth, thirteenth, and fourteenth centuries. Broadly speaking, what Morris did in both practice and precept was to call the attention of his countrymen to the transcendent beauty of the old work and particularly the work of this period. His immediate followers, who dominate applied art teaching in this country at the present time, go a step further and say, "Go back to Nature, the original source of all art inspiration, but *study Nature in the light of the old work.*" NATURE STUDY is therefore the *note* of present day art teaching. All forms of eccentricity under the guise of originality are tabbooed, in the belief that true originality will in time be developed, and students are encouraged to study the forms of natural objects, and preferably the most familiar objects of plant and animal life, and at the same time to keep their attention fixed upon the finest productions of the past. To sum up the matter, the decorative arts have certainly touched the lowest possible ebb of commonness and vulgarity, and a distinct and marked improvement has taken place during the past thirty years. No great and lasting advance may, however, be expected, much less a return to the great times of art, except by a complete and systematic training of the worker, and a corresponding elevation of taste on the part of the public.

G. W. R.

Design (*Eng., etc.*) The calculation of the dimensions, and the drawing of the parts of a machine or structure.

Designer (*Arts*). (1) One who makes an artistic design to be afterwards more elaborately executed. (2) One who designs figures and patterns for the manufacturer.

Desilverisation. The process of freeing lead from silver before it is made into white lead, and to fit it for use in chemical works, by Pattinson's Process (*q.v.*) In the Parkes Process the argentiferous lead is melted in large iron pots, and molten zinc is added. The silver possesses a greater affinity for zinc than it does for lead, so that on cooling most of the silver separates from the lead and combines with the zinc.

Dessue *or* **Dizzue** (*Mining*). Cutting out a thin lode in its entirety; also undermining or laying bare a lode. The term is chiefly used in Cornish mines.

Destructive Distillation (*Chem.*) *See* DISTILLATION.

Detachable (*Cycles*). Any part of a cycle which can be easily removed and replaced by the rider without any tools other than those carried in the valise may be termed detachable.

Detail *or* **Details** (*Fine Arts*). Particular and subordinate parts of a work of art or building, as distinguished from the larger parts or the general conception.

—— (*Architect*). Drawings generally intended for the use of workmen, *i.e.* WORKING DRAWINGS.

—— (*Photo.*) The smaller or the less visible parts of a picture, which are only to be seen in a well made negative.

Detent (*Watches, Clocks*). (1) In a chronometer escapement the delicate spring carrying the locking stone. (2) In a fusee watch or clock, or in a weight clock, the detainer of the maintaining ratchet, the object of which is to prevent the stopping of a timepiece while it is being wound.

Detrition (*Geol.*) A term generally restricted to the reduction in size of rock fragments by causes of a mechanical nature.

Deuterozoic Rocks (*Geol.*) The group of rocks comprising the DEVONIAN ROCKS, OLD RED SANDSTONE, and CARBONIFEROUS SYSTEM.

Developable Surface (*Eng., etc.*) *See* DEVELOPMENT.

Developed Winding (*Elect. Eng.*) A diagram showing the windings of an armature and their connections as they would appear if they were removed from the iron core and spread out on a flat surface.

Developer (*Photo.*) A substance which renders the LATENT IMAGE (*q.v.*) visible. Developers act by reduction (*q.v.*) of the salts of silver in the film: most of them are organic substances. *See* PYROGALLIC ACID, HYDROQUINONE, EIKONOGEN, ORTOL, *etc.*

Development (*Geometry, Eng., etc.*) (1) Giving full details of some part of a piece of work. (2) Drawing out on a flat surface the exact shape of a sheet of metal, etc., which is to be hammered or bent into some required shape. Only certain shapes can be drawn out thus; these are termed DEVELOPABLE SURFACES. Solids which are bounded by flat faces, cones, and cylinders are such surfaces; a sphere is not.

—— (*Music*). The working out of "subjects" in classical music; that part in sonata form following the double bar.

—— (*Photo.*) The production of a visible image on a sensitive film, which has been exposed or acted on by light. The process is one of REDUCTION (*q.v.*), metallic silver being produced in a very fine state of division in the case of ACID DEVELOPMENT, and

deposited on nuclei formed of silver sub-iodide (Ag_2I) or sub bromide (Ag_2Br). In ALKALINE DEVELOPMENT the image is formed by the reduction of the sub-salt itself to metallic silver. As these sub-salts are only formed in the parts acted on by light, it follows that these parts will become dense and opaque by the deposition in them of the particles of metallic silver. The more intense the action of the light, the more silver sub-iodide, etc., is formed, and hence there will be a gradation of light and shade in the picture. *See also* DEVELOPERS.

Development, Acid (*Photo.*) Development (*q.v.*) in which an acid (*e.g.* acetic acid) is added for the purpose of controlling the process, which would otherwise be too violent, and would result in the darkening of the whole plate.

——, Alkaline (*Photo.*) The use of an alkali, *e.g.* ammonia or soda, along with pyrogallic acid (or some equivalent reducing agent). The alkali greatly increases the affinity of the body for oxygen, upon which the developing action depends. In many cases this action would be barely visible if pyrogallic acid were used alone.

Deviation (*Phys.*) In optics the angle through which a ray of light is bent by a prism, lens, etc. *See also* MINIMUM DEVIATION.

——, Magnetic. The error of a compass which is due to the magnetic effect of an iron ship or of iron fittings in a wooden ship.

Device (*Her., etc.*) (1) An emblem or design representing a family, person, or quality; usually accompanied by a motto. Used in heraldry (an heraldic bearing, cognisance, etc.); also in painting and sculpture. (2) A motto or legend used in place of such a design. *See* ARMORIAL BEARINGS.

Devil (*Foundry*). A small portable grate containing a charcoal fire, used for drying the internal surfaces of a mould.

—— (*Paper Manufac.*) A machine used in the manufacture of paper for removing dust and dirt from rags.

—— (*Plumb.*) A plumber's firepot: used for heating solder, etc.

Devitrification (*Geol., etc.*) All substances of a vitreous or glassy character tend with lapse of time to undergo molecular rearrangement. Glass of Roman age, once more or less transparent, is now turbid, in consequence of such changes. The stained glass of mediæval age in many of our cathedrals (York, for instance) has become granular and brittle through devitrification. In Nature the process plays an important part, especially in connection with eruptive rocks which were at one time vitreous, and have become stony or lithoidal through this cause.

Devonian System (*Geol.*) The group of rocks of marine origin, typically developed in Devonshire, which were formed in the long interval between the close of the Silurian period and the commencement of the Carboniferous. The fossils have a facies intermediate in character between those of the two named. In Scotland and the north of England occur other types of rocks (the OLD RED SANDSTONES), chiefly formed under Continental conditions contemporaneously with the marine Devonian rocks.

Devonshire Lace. A local definition. It has no decided characteristics, the workers being clever at copying almost any style of lace that may be in demand.

Dew (*Meteorol., Phys.*) Moisture deposited from the atmosphere on a cool surface by a process of gradual condensation. The cold surface lowers the temperature of the air in contact with it until any water vapour in this air falls to the temperature at which it condenses.

Dewing (*Woollen Manufac.*) The process of damping the cloth, either to prepare it for raising or to improve its handle.

Dew Point (*Phys., etc.*) The temperature at which moist air becomes saturated and begins to deposit its moisture, thus forming dew.

Dexter (*Her.*) The right hand side of the shield, but opposite to the left hand of the spectator from the front.

Dextrine *or* **British Gum** (*Chem.*) $(C_6H_{10}O_5)_n$. A white solid; soluble in water; insoluble in absolute alcohol; dextrorotatory; does not reduce Fehling's solution when pure; gives no colour with iodine; its solution heated with acids yields maltose and then glucose (dextrose). The pure substance is made by the action of malt extract on starch paste at about 60°; after filtering, maltose is precipitated by repeated treatment with alcohol, and finally the dextrine is thrown out by adding sufficient absolute alcohol. Commercial dextrines, which are always impure, are made by heating starch or by acting on starch with dilute sulphuric acid for a short time only; the acid is then precipitated with chalk, the clear liquid drawn off, and the residue pressed; the whole of the clear liquid is then concentrated in vacuum pans. As dextrine is a strong adhesive material, it is used for gumming envelopes, labels, and papers, finishing and thickening cotton, lace, etc., and is also sometimes used as a binder in making watercolours (*q.v.*) Dextrine required for commercial use should be free from acidity, dissolve almost wholly in cold water, and yield a solution of a light brown or yellowish colour.

Dextrorotatory (*Phys., Chem.*) A compound is said to be dextrorotatory when it has the power of rotating the plane of polarisation of light to the right *See* POLARISED LIGHT. If the substance is a solid, it is examined in solution in a suitable inactive solvent. *See* ASYMMETRIC CARBON ATOM.

Dextrose, Glucose, Grape Sugar (*Chem.*), $CH_2OH.(CHOH)_4.CHO$. A white crystalline solid, anhydrous when crystallised from strong alcohol, containing one molecule of water when crystallised from water; the anhydrous solid melts at 146°. It is dextrorotatory, and the freshly made solution rotates the plane of polarisation about twice as strongly as a solution which has stood for some time (bi-rotation); it is less sweet than cane sugar. Dextrose is readily soluble in water; alcohol diminishes its solubility, and anhydrous dextrose is insoluble in absolute alcohol. It occurs in honey and many sweet fruits, always along with lævulose (*q.v.*); also very largely in the urine in diabetes mellitus. In combination it occurs in the important class of substances called GLUCOSIDES (*q.v.*) Dextrose may be prepared by inverting a solution of cane sugar (that is, converting it into dextrose and lævulose) by the action of yeast or dilute sulphuric acid (after inversion the acid must be removed by baryta water), evaporating the solution to crystallising point under reduced pressure, washing the crystals with rectified spirit, and then crystallising from the same till pure. The commercial glucose which is used in making beer, sweets, jams, etc., contains dextrine, and is made by the action of dilute sulphuric acid on various kinds of starch. Dextrose has been synthesised Formal-

dehyde (CH_2O), acrolein dibromide (CH_2Br . $CHBr$. CHO), and glycerose, a mixture of the ketone and aldehyde of glycerine (*q.v.*), all undergo condensation to *a*-acrose, which is inactive lævulose. This yields on reduction inactive mannitol, from which inactive mannonic acid (or its lactone) can be obtained by oxidation. Inactive mannonic acid can be resolved by strychnine into the dextro- and lævo-acids. The dextro-acid, when heated to 150° with quinoline, is partially changed to *d*-gluconic acid (a stereoisomeride), which on reduction yields glucose. The following are important reactions of glucose: it reduces Fehling's solution and also ammoniacal silver nitrate; ferments with yeast, giving alcohol and carbon dioxide as chief products; unites with CaO, BaO, SrO, forming $C_6H_{12}O_6CaO$, etc. Carefully oxidised, it yields the monocarboxylic acid gluconic acid, CH_2OH . $(CHOH)_4COOH$. More strongly oxidised, saccharic acid is obtained, $COOH(CHOH)_4COOH$. Like aldehydes generally, it unites with hydrocyanic acid, with hydroxylamine, and with phenylhydrazine, forming cyanhydrins, oximes, and hydrazones respectively. With two molecules of phenylhydrazine, the very important glucosazone

$$CH_2OH(CHOH)_3 . C . CH : N . NHC_6H_5 \atop {\quad\quad\quad\quad\quad\quad\quad\quad :\atop N . NHC_6H_5}$$

is formed. *See* LÆVULOSE *and* OSAZONES. The formation of this substance serves as a test for glucose. As glucose is a pentahydric alcohol, it has the power of forming esters with acids; thus it forms a penta-acetate. On reduction, glucose yields SORBITOL, a hexahydric alcohol stereoisomeric with mannitol.

Dextrotartaric Acid (*Chem.*) Ordinary TARTARIC ACID (*q.v.*)

Dhoolie (*Cotton Weaving*). (1) A calico cloth with various bright coloured threads near the selvedges, forming a border. Sometimes a figured border is put in and called FIGURED DHOOLIE. Mostly for export to India. (2) The name of the loin cloth worn by Hindus.

Dhurra (*Botany*). *Sorghum vulgare* (order, *Gramineæ*). A cereal grown in Southern Europe, Egypt, and India, under the name of dhurra or dari, great millet, or guinea corn.

Di (*Chem.*) Symbol for DIDYMIUM (*q.v.*)

Diabase (*Geol.*) A name applied in very different senses by different writers to rocks allied in composition and structure to dolerite (*q.v.*) It is impossible to give an exact definition which would be generally accepted. On the Continent the term is usually applied to a basic eruptive rock (usually a dolerite) which is of pre-tertiary age.

Diadem. A CROWN (*q.v.*) (1) Anciently a band or fillet, either plain or adorned with jewels, worn as a badge of royalty, especially by Oriental sovereigns. It was made of linen, cloth, or silk, generally white in colour, and passed round the forehead, the ends being tied behind, and falling on the neck. (2) The aureola or crown of a martyr.

—— (*Her.*) One of the arches rising from the rim of a crown (or coronet) and supporting the mound and cross. *See* DIADUMENUS.

Diadumenus, a (*Sculp.*) The name given to statues in which the figure has a fillet or diadem (*q.v.*) bound round the head. The name was given to a celebrated statue by Polycletus.

Diagonal (*Geometry*). A line drawn between opposite corners of a geometrical figure.

Diagonal (*Eng.*) A BRACE or STRUT (*q.v.*) running diagonally across the openings of a built up girder or other framed structure.

—— (*Textile Manufac.*) A type of woven design of the twilled character.

Diagonal Bond (*Build.*) Bricks laid diagonally in the interior of thick walls.

Diagonal Winch (*Eng.*) A STEAM WINCH (*q.v.*) in which the cylinders are fixed at an angle with the base plate. This arrangement takes much less room than a horizontal one, and is much more rigid than a vertical engine.

Diagram. (1) An illustration or drawing which represents some part of an object, or illustrates some principle. (2) An INDICATOR DIAGRAM. Also a figure or drawing for the purpose of demonstrating the properties of any geometrical figure, as a triangle, circle, etc.; any illustrative figure, etc.

Diagraph. An optical instrument used for drawing, mechanically, projections of objects, maps, etc., on a scale proportionate to the distance of the instrument from the object. It consists of a glass, to which is attached a pencil governed by cords. The operator looking through the glass follows the lines of the object to be delineated, and as he moves the glass the pencil also moves and reproduces it.

Dial. (1) In general a disc or plate on which graduations are marked; these graduations enable the position of some form of pointer or index to be read off. (2) A MINER'S DIAL (*q.v.*)

Diallage (*Min.*) A clear green monosymmetric pyroxene occurring in serpentine and in some Gabbros (*q.v.*) It is a variety of Augite which has undergone some change arising from the action of subterranean waters. *See* PYROXENE.

Dialling *or* **Latching** (*Surveying*). Local terms for mine surveying.

Dialogite (*Min.*) Manganese carbonate, $MnCO_3$. In rhombohedral crystals, often rose red (hence the synonym RHODOCHROISITE); also yellow or brown; also massive and incrusting. Dissolves in warm hydrochloric acid. From Shropshire, Warwickshire, Ireland, Saxony, Hungary, North America.

Dialysed Iron (*Chem.*) Ferric hydroxide dissolves in a solution of ferric chloride. If such a solution be placed in a dialyser (a glass vessel open at the top and bottom: for use as a dialyser the bottom is covered with parchment and the vessel floated on water, the liquid to be dialysed being placed in the vessel), the solution forms hydrochloric acid, and a solution of ferric hydroxide remains on the dialyser. This is called dialysed iron; it is used in medicine where other iron preparations are unsuitable.

Dialysis (*Chem.*) Certain substances, such as albumin, gelatine, silicic acid, etc., having very high molecular weights when in solution in water, will not pass through a membrane such as bladder or parchment when the latter is floated on water; while most crystalline soluble substances will do so. The process of separating, by the use of such a membrane, a mixture of substances of the first class from substances of the second class is called DIALYSIS. For an example, *see* DIALYSED IRON.

Diamagnetism (*Phys.*) Substances whose magnetic permeability is less than unity (*i.e.* less than that of air), or whose magnetic susceptibility is negative, are said to be diamagnetic. Unlike paramagnetic substances such as iron, they tend, in a

magnetic field, to set themselves so that as few lines of force as possible pass through them, and hence are repelled by a magnet pole.

Diameter. (1) The line drawn across a figure; usually a line drawn through its centre. (2) The length of such a line.

Diameter of Commutation (*Elect. Eng.*) A diameter of a commutator drawn through the points of contact of the brushes.

Diameter Theory (*Textile Manufac.*) The theory of setting the cloths, based on the diameter of the threads and the number of intersections of warp and weft in a repeat of the weave.

Diametral Pitch (*Eng.*). The number of teeth on a spur wheel divided by the diameter of the PITCH CIRCLE (*q.v.*)

Diamidoazobenzene (*Chem.*) CHRYSOIDINE (*q.v.*)

Diamines (*Chem.*) When one atom of hydrogen from both of two molecules of ammonia is replaced by a divalent radical, the resulting compound is called a diamine; *e.g.* ethylene diamine is $N\begin{cases} CH_2 . CH_2 \\ H \quad\quad\; H \\ H \quad\quad\; H \end{cases}N$ and metaphenylene diamine is $C_6H_4\begin{cases} NH_2 \\ NH_2 \end{cases}$ (1 : 3). The PTOMAINES, PUTRESCINE, and CADAVERINE (*q.v.*) are diamines.

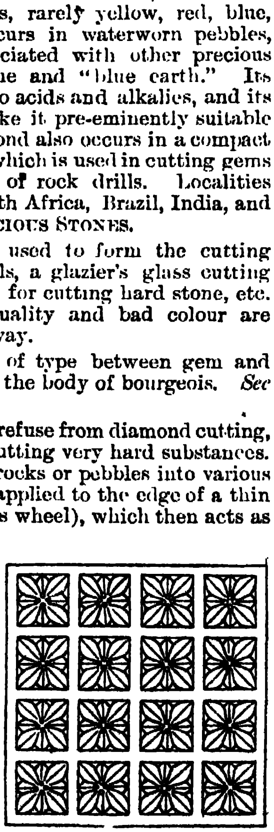
Diamond (*Min.*) Carbon in its cubic form (*cf.* GRAPHITE). Occurs in octahedra, often with curved faces. Colourless, rarely yellow, red, blue, or black. It often occurs in waterworn pebbles, in alluvial deposits associated with other precious stones, and in sandstone and "blue earth." Its hardness, its resistance to acids and alkalies, and its high refractive index make it pre-eminently suitable for use as a gem. Diamond also occurs in a compact variety known as BORT, which is used in cutting gems and to arm the crowns of rock drills. Localities for the diamond are South Africa, Brazil, India, and Australia. *See also* PRECIOUS STONES.

—— (*Trades*). Often used to form the cutting point of a tool, *e.g.* drills, a glazier's glass cutting tool, some forms of saws for cutting hard stone, etc. Diamonds of inferior quality and bad colour are generally used in this way.

—— (*Typog.*) A size of type between gem and pearl, and equal to half the body of bourgeois. *See* TYPE.

Diamond Dust. Fine refuse from diamond cutting, used for grinding and cutting very hard substances. For example, in cutting rocks or pebbles into various shapes, diamond dust is applied to the edge of a thin rotating disc (a lapidary's wheel), which then acts as a fine saw.

Dianella Tasmanica (*Botany*). Order, *Liliaceæ*. The "Broad Leaved Flax Lily" of Tasmania and Australia yields a good fibre for papermaking, and is easily grown.



DIAPER (*Architect.*)

Diaper (*Architect.*) A surface ornament, either carved or painted, usually repeated in squares, and applied to the face of a wall. It was extensively used in England during the EARLY ENGLISH and DECORATED periods.

Diaper (*Her.*) A surface decoration of a shield used only as an ornament. It must not be considered as a charge.

—— (*Textiles*). A class of cloth in which the design is formed by alternate squares or lines of warp and weft face, and which is reversible. The old DIAPERS or DORNICS were usually of a damboard or dice pattern, and were used for coarse table-cloths; but now diapers are mostly of the bird's-eye or small diamond pattern, and are used for many purposes, such as children's bibs, towellings, dusters, etc. The name "Dornick" is derived from Tournay, in France. Synonymous terms, DICED, DIMITY.

Diaphaneity. The property of transmitting light. When a substance possesses perfect diaphaneity, it is said to be TRANSPARENT; when it transmits some light, but is not clear enough to allow objects to be seen through it, it is said to be TRANSLUCENT. When no light can pass, it is OPAQUE.

Diaphragm. A general name for a partition across a space or cavity.

—— (*Photo.*) A partition with a circular opening placed in or near the lens to reduce the diameter of the pencil of rays passing through it. A small opening increases the sharpness of the image, but diminishes the intensity of illumination of the plate, and therefore necessitates a longer exposure.

—— (*Zoology*). The partition between the thorax and abdomen in a mammal.

Diastase *or* **Amylase** (*Chem.*) An ENZYME (*q.v.*) of unknown composition; it contains carbon, hydrogen, nitrogen, oxygen, sulphur, and ash. It can be obtained from malt in a variety of ways; *e.g.* the malt is treated with alcohol, the residue is extracted with glycerine, and the glycerine solution is precipitated with a mixture of alcohol and ether. The precipitate is dissolved in water, and once more precipitated by alcohol. Diastase is a yellowish-white amorphous powder. Diastase (or substances closely allied to it in properties) is extremely wide-spread in nature, occurring in plants and animals; *e.g.* the so-called PTYALIN of the saliva is a diastase. The chief property of diastase is its power of converting starch into dextrine and the sugar maltose. The most favourable temperature for its action is about 54°: it is destroyed (when in solution) at 75°. Diastase is the most important constituent of MALT EXTRACT, but many preparations, on account of the high temperature employed in their manufacture, contain no diastase. *See also* ENZYMES.

Diastyle (*Architect.*) The name given to the spacing of the columns in a Grecian temple when the space between the columns is equal to three times the lower diameter of the shaft. *See* ARÆOSTYLE, PYCNOSTYLE, SYSTYLE, EUSTYLE, *and* INTERCOLUMNIATION.

Diathermanous (*Phys.*) Substances which are transparent to radiant heat are said to be Diathermanous (*e.g.* rocksalt).

Diatom (*Biology*). *Diatomaceæ*, a class of very minute unicellular plants (*Algæ*) found in fresh and salt water. Their silicified valves occur as fossils, and form the deposits known as DIATOM EARTH.

Diatom Earth. Accumulations of the siliceous cases or frustules of the minute and lowly form of vegetable life known as diatoms. The "earth" in most cases has gradually accumulated on the bottom

of fresh water lakes. It has a considerable commercial value, and under the name of DIATOMITE is largely employed in the manufacture of dynamite. *Also termed* KIESELGUHR *and* MOUNTAIN MEAL.

Diatomic Molecule (*Chem.*) A molecule of an element containing two atoms. Thus the molecules of hydrogen, oxygen, nitrogen, and chlorine are each believed to consist of two atoms of the respective elements.

Diatonic (*Music*). Consisting chiefly of tones, as opposed to chromatic. Melody is formed wholly on the diatonic scale.

Diatonic Scale (*Sound*). A series of notes whose frequencies are proportional to the quantities

$$1,\ \tfrac{9}{8},\ \tfrac{5}{4},\ \tfrac{4}{3},\ \tfrac{3}{2},\ \tfrac{5}{3},\ \tfrac{15}{8},\ 2.$$

This gives a succession of the following intervals: Tone, Tone, Semitone, Tone, Tone, Tone, Semitone.

Diazoamidobenzene (*Chem.*) *See* DIAZO REACTIONS.

Diazomethane (*Chem.*), $\mathrm{CH_2}\left<\begin{array}{c}\mathrm{N}\\ \|\\ \mathrm{N}\end{array}\right.$. A yellow gas; no smell; poisonous; attacks the eyes and skin. Water decomposes it, forming methyl alcohol; acids give the corresponding methyl ester. It is obtained by the action of alkalis upon nitrosomethyl urethane:

$$\mathrm{CO}\left<\begin{array}{l}\mathrm{N\,.\,CH_3}\\ \ \ |\\ \ \ \mathrm{NO}\\ \mathrm{OC_2H_5}\end{array}\right. + \mathrm{HONa} = \mathrm{CO}\left<\begin{array}{l}\mathrm{ONa}\\ \mathrm{OC_2H_5}\end{array}\right. + \mathrm{H_2O} + \left.\begin{array}{c}\mathrm{N}\\ \|\\ \mathrm{N}\end{array}\right>\mathrm{CH_2}.$$

See URETHANES.

Diazonium Salts (*Chem.*) *See* DIAZO REACTIONS.

Diazo Reactions (*Chem.*) When an aromatic amine is converted into a salt and a solution of the salt treated with nitrous acid below 5°, a diazonium salt is produced. This process is called DIAZOTISING, and the reaction is called the DIAZO REACTION. For example, when one molecular proportion of aniline is dissolved in between two and three molecular proportions of hydrochloric acid diluted with water, a solution of aniline hydrochloride is formed, and one molecular proportion of the acid is left over. The solution is now cooled to 0°, and one molecular proportion of sodium nitrite in strong solution is gradually added; this, with the free acid, forms nitrous acid, which, with the aniline hydrochloride, forms the diazonium chloride

$$\mathrm{C_6H_5NH_2\,.\,HCl + ON\,.\,OH = C_6H_5\underset{\displaystyle Cl}{N}\!:\!N + 2H_2O}.$$

The diazonium salts are colourless, crystalline solids soluble in water and insoluble in ether; they are unstable, and some (*e.g.* the nitrate) are explosive. They are usually only prepared in solution, and their very great importance consists in the fact that they undergo many important reactions. The following are examples: (1) Warmed with alcohol, the group $\mathrm{N_2X}$ is replaced by hydrogen, *e.g.* $\mathrm{C_6H_2Br_3N_2Cl}$ gives $\mathrm{C_6H_3Br_3}$. (2) Boiled with water, they give phenols, *e.g.* $\mathrm{C_6H_4CH_3N_2Cl}$ gives $\mathrm{C_6H_4CH_3OH}$. (3) Heated with cuprous chloride, bromide, or cyanide, chloro, bromo, and cyanogen derivatives are formed, *e.g.* benzene diazonium chloride with cuprous cyanide gives PHENYL CYANIDE (BENZONITRITE), $\mathrm{C_6H_5CN}$. (4) Heated with potassium iodide, the diazonium sulphate gives an iodo compound, *e.g.* $\mathrm{C_6H_5N_2HSO_4}$ gives PHENYL IODIDE (IODOBENZENE), $\mathrm{C_6H_5I}$. (5) The diazonium bromides add on two atoms of bromine and form perbromides, *e.g.* $\mathrm{C_6H_5NBr\,.\,NBr_2}$: the latter compound with ammonia gives DIAZOBENZENEIMIDE, $\mathrm{C_6H_5\,.\,N}\left<\begin{array}{c}\mathrm{N}\\ \|\\ \mathrm{N}\end{array}\right.$, a liquid with stupefying odour. (6) Reduced with stannous chloride, benzene diazonium chloride gives PHENYLHYDRAZINE HYDROCHLORIDE, $\mathrm{C_6H_5\,.\,HN\,.\,NH_2HCl}$. (7) With aniline, benzene diazonium chloride forms DIAZOAMIDOBENZENE, $\mathrm{C_6H_5N:N\,.\,NHC_6H_5}$, a yellow crystalline solid which, when heated with aniline and aniline hydrochloride, is changed to the isomeric AMIDOAZOBENZENE, $\mathrm{C_6H_5\,.\,N:N\,.\,C_6H_5NH_2}$, a yellow crystalline solid: its disulphonic acid is a valuable dye—FAST YELLOW. A few fatty diazo compounds are known; thus DIAZOACETIC ESTER, $\begin{array}{l}\mathrm{CH}\left<\begin{array}{c}\mathrm{N}\\ \|\\ \mathrm{N}\end{array}\right.\\ |\\ \mathrm{COOC_2H_5}\end{array}$ is obtained by the action of nitrous acid upon the hydrochloride of ethyl aminoacetate, $\begin{array}{l}\mathrm{CH_2NH_2HCl}\\ |\\ \mathrm{COOC_2H_5}\end{array}$.

Dibasic Acids (*Chem.*) Acids which form two salts with a monovalent element, such as sodium, potassium, or silver; or with a monovalent group, such as the ammonium group ($\mathrm{NH_4}$), or the methyl ($\mathrm{CH_3}$) or ethyl ($\mathrm{C_2H_5}$) groups. Thus sulphuric acid, $\mathrm{H_2SO_4}$, is a dibasic acid because it forms the salts $\mathrm{NaHSO_4}$ (sodium hydrogen sulphate) and $\mathrm{Na_2SO_4}$ (sodium sulphate), etc.

Dicarboxylic Acids (*Chem.*) Organic acids containing two $-\mathrm{COOH}$ groups are called dicarboxylic acids. Thus, the simplest possible dicarboxylic acid is oxalic acid, $\begin{array}{l}\mathrm{COOH}\\ |\\ \mathrm{COOH}\end{array}$.

Diced. *See* DIAPER.

Dichlamydeous (*Botany*). The term used in description of a flower when both whorls of the perianth are present.

Dichroism (*Min.*) The property some minerals have of exhibiting two different colours when viewed in two different directions, *e.g.* IOLITE or DICHROITE.

Dichroite (*Min.*) A synonym for IOLITE (*q.v.*)

Dichromate Cell. *See* CELLS, PRIMARY.

Dicotyledones (*Botany*). One of the two divisions of flowering plants, characterised by the presence of two cotyledons or seed leaves in the embryo.

Didactics. The art or science of teaching.

Didymium (*Chem.*) This substance occurs in cerite along with Cerium, Lanthanum, and Samarium: it was formerly regarded as a single element, as solutions of its salts yield a characteristic absorption spectrum. But it has been resolved by fractional crystallisation of the double nitrate with ammonium into two others: NEODYMIUM, giving pink salts; and PRASEODYMIUM, giving green salts, and both having characteristic absorption spectra. Neodymium is itself most probably not a single element.

Die (*Architect.*) The cube-shaped body of a pedestal. It is also known as the dado. *See* PEDESTAL *and* DADO; *also* ARCHITECTURE, ORDERS OF.

—— (*Eng., etc.*) (1) An engraved stamp employed for impressing a design upon some softer material, such as coins, medals, etc. Dies are often used in pairs for impressing different designs on the opposite

sides of the article stamped. (2) A cutting tool used for forming an external screw thread. *See* STOCKS AND DIES.

Die Box (*Eng.*) The part of a SCREWING MACHINE (*q.v.*) which contains the DIES.

Die Chuck (*Eng.*) A chuck in which work is held by two (or three) small jaws, carried in radial slots along which they can be moved to or from the centre of the chuck. Sometimes the jaws are actuated by mechanism, so that they move simultaneously; the chuck then becomes SELF-CENTRING.

Dielectric (*Elect.*) Insulating or non-conducting material through which lines of electric force run from one charged body to another. *See also* SPECIFIC INDUCTIVE CAPACITY.

Diesis (*Phys.*) The interval between two notes whose frequencies are as 25 : 24. It is the difference between a minor tone (frequency ratio $\frac{10}{9}$) and a limma ($\frac{16}{15}$).

Die Square (*Carp.*) Rough timber of a square section, not sawn.

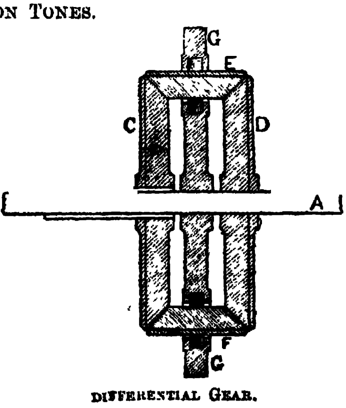
Diethylamine (*Chem.*) $NH(C_2H_5)_2$. A colourless inflammable liquid with strong ammonia-like smell; boils at 56°; soluble in water; a strong base. For preparation, *see under* ETHYLAMINE. It is a secondary amine. Its chief reactions are: (1) With ethyl oxalate it forms ETHYL DIETHYLOXAMATE, $\begin{array}{l}CON(C_2H_5)_2\\ |\\ COOC_2H_5\end{array}$, a liquid. (2) With nitrous acid it forms NITROSODIETHYLAMINE $(C_2H_5)_2N.NO$, a yellow liquid. (3) With ethyl iodide it forms TRIETHYLAMINE HYDRIODIDE, $N(C_2H_5)_3HI$. (4) With acetylchloride it forms DIETHYLACETAMIDE, $(C_2H_5)_2N.OC.CH_3$.

Difference of Phase (*Phys., etc.*) *See* HARMONIC MOTION.

Differences, Marks of, *or* **Brisures** (*Her.*) Distinguishing marks or figures added to heraldic compositions for the purpose of identifying different members of a family who have the right to bear the paternal arms. For instance, eldest sons bear their fathers' arms differenced with a label as a distinguishing mark; the second bears a crescent, the third a mullet, the fourth a martlet, and so forth. These are used during the lifetime of the father.

Difference Tone (*Sound*). When two notes sounding together produce beats (*q.v.*), a tone can sometimes be heard whose frequency is equal to the difference of the frequencies of the two original tones. This deeper tone is termed a Difference Tone. *See also* COMBINATION TONES.

Differential Gear (*Motor Cars*). A train of wheels connecting the two halves of the driving axle of a car with the shaft which transmits the power from the engine. This permits the wheels of the car to revolve at different rates when turning a corner, but causes both to revolve together when driving straight forward. In a typical form A and B are the two halves of the axle; D and C are bevel wheels keyed on A and B; G is the rim of the sprocket wheel, *i.e.* the wheel by means of which the power is transmitted from the engine to A and B; E and F are small bevel wheels, gearing with C and D, and carried on axles fixed to the sprocket wheel G. In straightforward driving E and F do not rotate, and therefore C and D turn with G. When the whole vehicle is caused to turn from its previous straight path, E and F can rotate in such a way as to allow a difference in the rate of rotation of the two half axles A and B.



DIFFERENTIAL GEAR.

Differential Motion (*Cotton Weaving*). A very important and essential motion on the flyer frames for determining the reduction in speed of bobbin spindles as the diameter of bobbin increases during the winding on of the roving which is given off by the draw rollers. There are several motions, the chief of which are as follows: (1) Holdsworth's; (2) Curtis & Rhodes'; (3) Dobson & Barlow's; (4) Tweedale's; (5) Brooks & Shaw's. Sometimes termed "Jack-in-the-box."

—— (*Eng.*) (1) Differential gear (*q.v.*) such as is used in motor cars. (2) Any mechanism in which a motion is obtained which is the difference of two separate motions; *e.g.* in the so-called Chinese windlass, in which one end of a chain is unwound from a barrel, while the other end is wound up on a larger barrel, thus raising the loop or bight of the chain at a slow rate.

Differential Pulley. A block with a set of pulleys and an endless chain. The mechanical advantage depends on the difference between the diameters of the pulleys.

Diffraction. The general name for the phenomena produced when light passes through any very small opening or past some obstacle casting a shadow. According to ordinary experience in such cases sharp shadows are produced, whereas, according to any wave theory, sharp shadows should not be produced. When, however, light diverges from a point source or a very narrow slit, maxima and minima of illumination are produced outside, and sometimes inside, the geometrical shadow, giving rise to what are termed DIFFRACTION BANDS, and these can be shown to be exactly in accordance with theory when the very small length of light waves is taken into account.

Diffraction Grating. An arrangement practically equivalent to a large number of very narrow slits close together, thus vastly increasing the brilliancy of the diffraction effects obtained. They are produced by ruling some surface, such as glass (transmission grating) or metal (reflection grating) with from 5,000 to 40,000 lines or scratches to the inch. The best gratings are ruled on a concave metallic mirror of small curvature, a method introduced by Rowlands. Good gratings are very costly, but useful replicas can be obtained on gelatine films. Diffraction gratings are used for the production of spectra without the aid of a prism, and their main importance lies in the fact that they afford almost the only practical method of accurately measuring the wave length of light.

Diffusiometer (*Phys., Chem.*) A piece of apparatus used in examining the rate of diffusion of gases. It is merely a straight glass tube, one end of which is closed by a porous material such as plaster of Paris or a thin piece of gas carbon, the other end being open. The porous end is covered with a sheet

of rubber; the tube is filled with mercury and inverted over mercury, and the gas to be examined is passed in. The level of mercury inside and outside being the same, the rubber is removed at a given instant, and the process of diffusion begins. The mercury levels being kept as nearly as possible the same during the experiment, the rubber cap is put on again after a known interval, and the amount of air which has entered the tube, as determined by analysis, during the time of the experiment measures the rate of diffusion of the gas relative to that of air.

Diffusion (*Phys.*, *Chem.*) This term in its widest sense implies the spontaneous mixing which occurs when two or more substances are brought in contact with each other. The phenomenon is most pronounced in gases. When two gases are brought together they rapidly mix, even against gravity. Thus, if two flasks be joined together by a glass tube passing through rubber stoppers, and the lower flask be filled with carbon dioxide and the higher with hydrogen, the gases will form a homogeneous mixture after some time, in spite of the fact that the carbon dioxide is twenty-two times as heavy as the hydrogen. Graham showed by means of the DIFFUSIOMETER (*q.v.*) that gases diffuse at a rate which varies inversely as the square roots of their densities; *e.g.* the density of hydrogen being one and that of oxygen sixteen, hydrogen diffuses four times as quickly as oxygen. Liquids also have the power to diffuse into each other; but the process is incomparably slower than in the case of gases, and there is no such simple law of diffusion in the case of liquids as that which holds in the case of gases. Dissolved substances have also the property of diffusing through the liquid serving as solvent; thus a solution of copper sulphate may be placed in a tall cylinder and water cautiously poured upon it so as not to mix with the solution. On standing, the copper sulphate will be seen to pass very slowly up the cylinder into the water. Solids also diffuse into each other, but very slowly. A plate of high carbon steel pressed against a plate of pure iron gives up carbon to the iron even at ordinary temperatures. The phenomena of diffusion are explained on the supposition that the molecules of matter are in a state of rapid motion. In gases the molecules have the greatest freedom, so that mixture takes place readily; while in liquids and solids the molecular conditions are much more complex, and diffusion is much slower. The passage of a gas through a porous material into another gas is also called diffusion, and the law of gaseous diffusion holds the same whether there is a partition or not. A partition is useful when it is desired to effect a partial separation of two gases which differ sufficiently in density.

Diffusivity (*Phys.*) The ratio between the conductivity of a substance and its specific heat per unit volume. If k = the coefficient of conductivity, s the specific heat, and ρ the density of the body, the diffusivity or, as it is also called, the coefficient of thermometric conductivity $= \dfrac{k}{s\rho}$.

Digester (*Paper Manufac.*) A strong steel vessel used for boiling rags, esparto, and other raw materials.

Digesters (*Chem. Eng.*) Apparatus of various forms (generally provided with stirrers or a false bottom) for "cooking" materials with steam, usually under pressure, *e.g.* in the separation of oil, fat, or grease from fish offal, slaughter-house refuse, and bones.

Digestion (*Zoology*). The process by which the food is changed into soluble substances that will readily diffuse through the walls of the alimentary canal into the blood. *See* CHYME, *etc.*

Digger (*Civil Eng.*) A term applied to a mechanical excavator.

Digitalin. The alkaloid obtained from the leaves of the foxglove, *Digitalis purpurea* (order, *Scrophulariaceæ*).

Diglyph (*Architect.*) A projecting face used in the Doric entablature, similar to a triglyph, but having only one complete and two half channels. *See* TRIGLYPH.

Dihydric Alcohols and Phenols (*Chem.*) Alcohols and phenols containing two hydroxy groups. Thus glycol is a dihydric alcohol, $\begin{array}{l} CH_2OH \\ | \\ CH_2OH \end{array}$; hydroquinone is a dihydric phenol, $C_6H_4(OH)_2$ (1 : 4). *See also* ALCOHOL.

Dihydro (*Chem.*) A prefix implying the addition of two hydrogen atoms to a compound. Thus dihydrobenzene is a compound formed by the addition of two atoms of hydrogen to benzene: C_6H_6, Benzene. C_6H_8, Dihydrobenzene.

Dihydroxy (*Chem.*) A prefix implying the presence in a compound of two hydroxy groups. Thus tartaric acid is called dihydroxysuccinic acid, because it may be regarded as succinic acid in which two hydrogen atoms are replaced by two hydroxy groups.

$$\begin{array}{lcl} CH_2COOH & \quad & CHOHCOOH \\ | & & | \\ CH_2COOH & & CHOHCOOH \\ \text{Succinic acid.} & & \text{Dihydroxysuccinic acid.} \end{array}$$

Dihydroxytartaric Acid (*Chem.*), $\begin{array}{l} C(OH)_2COOH \\ | \\ C(OH)_2COOH \end{array}$. *Also called* DIOXYTARTARIC ACID. An unstable crystalline solid melting at 114°. To make it tartaric acid is dissolved in fuming nitric acid, mixed with concentrated sulphuric acid, and allowed to stand; the solid, which separates, is carefully brought into ice cold water and allowed to stand some days. The solution of the acid so obtained yields a nearly insoluble sodium salt; it has been suggested as a test for sodium. With phenylhydrazine parasulphonic acid it yields a beautiful golden yellow dye, TARTRAZINE,

$$\begin{array}{l} HOOC\,.\,C : N - NHC_6H_4SO_2OH \\ \qquad\quad | \\ HOOC\,.\,C : N - NHC_6H_4SO_2OH \end{array}$$

Dike. A DYKE (*q.v.*)

Diketones (*Chem.*) Compounds containing two ketone (—CO—) groups. The simplest diketone is diacetyl, $CH_3CO\,.\,COCH_3$. When the ketone groups are adjacent they are called α or 1 : 2 diketones; when separated by a CH_2 group, β or 1 : 3 diketones; and so on. DIACETYL is interesting because it has a yellow colour and a smell like quinone (*q.v.*), which is an aromatic diketone. ACETONYLACETONE is important because of the readiness with which it yields derivatives of the heterocyclic ring compounds, FURFURANE, THIOPHENE, and PYRROL. It is a pleasant smelling liquid, boiling at 194°, and may be prepared from ethyl acetoacetate (*q.v.*) by making the sodium compound, treating this with iodine, and allowing the resulting ethyl diacetyl-

succinate to stand in contact with caustic soda solution.

$$\begin{array}{l} CH_3COCH \,.\, COOC_2H_5 \\ \;\;| \qquad\qquad\qquad\qquad + 2H_2O \\ CH_3COCH \,.\, COOC_2H_5 \end{array}$$

$$\begin{array}{l} CH_3CO \,.\, CH_2 \\ \qquad\quad | \qquad + 2CO_2 + 2C_2H_5 \,.\, OH \\ CH_3CO \,.\, CH_2 \end{array}$$

Acetonylacetone can exist in the tautomeric (*see* TAUTOMERISM) form, $CH_3C \,.\, OH = CH - CH = C \,.\, OH \,.\, CH_3$. Heated with phosphorus pentoxide, it forms *aa*-DIMETHYL FURFURANE:

$$\begin{array}{l} CH_3C = CH \\ \quad OH \\ \quad OH \\ CH_3C = CH \end{array} \qquad \begin{array}{l} CH_3 \,.\, C = CH \\ O\langle \\ CH_3 \,.\, C = CH \end{array} \quad + H_2O.$$

With phosphorus pentasulphide (which withdraws water and gives SH_2) we get *aa*-DIMETHYL THIOPHENE,

$$\begin{array}{l} CH_3 \,.\, C = CH \\ S\langle \quad | \\ CH_3 \,.\, C = CH \end{array}$$

With ammonia it gives *aa*-DIMETHYL PYRROL,

$$\begin{array}{l} CH_3 \,.\, C = CH \\ \quad OH \\ \quad OH \\ CH_3 \,.\, C = CH \end{array} \quad NH = 2H_2O + HN\langle \begin{array}{l} CH_3 \,.\, C = CH \\ \\ CH_3 \,.\, C \quad CH \end{array}$$

Dilatometer (*Phys.*) An instrument for determining the cubical expansion of liquids. In one form a bulb is filled with the given liquid at a known temperature, and the increase in volume is obtained by observing the rise of the liquid in the neck attached to the bulb, the cross section of this neck having been accurately determined beforehand. On making a suitable correction for the expansion of the bulb, the true coefficient of cubical expansion of the liquid can be calculated if we know the original volume and the rise in temperature to which the liquid has been subjected.

Dill (*Botany*). *Peucedanum graveolens* (order, *Umbelliferae*). The dried fruits produce on distillation an oil used in pharmacy.

Dillueing (*Mining*). Cornish term for washing powdered ore.

Diluvium (*Geol.*) A name applied by the older generation of geologists to all the superficial accumulations, and especially to those now regarded as of glacial origin. Formerly these diluvial deposits were supposed to have been formed by the Flood, or by some vast and destructive debacle.

Dimensions (*Eng., etc.*) The measurements of work which are shown on working drawings.

Dimensions of Units. The power which shows how a derived unit is related to a fundamental unit; *e.g.* a unit of volume (derived) varies as the *third* power of the fundamental unit of length on which it depends, and therefore the unit of volume is said to be of dimensions three in length. The unit of velocity varies directly as the unit of length, and inversely as the unit of time; its dimensions, therefore, are 1 in length and -1 in time. *See also* UNITS.

Dimethylamine (*Chem.*) $(CH_3)_2NH$. A gas; when liquefied it boils at 7°. In its properties it closely resembles diethylamine (*q.v.*), and it may be prepared in a similar way. It is also prepared by boiling nitrosodimethylaniline (*q.v.*) with caustic soda.

Dimethylaniline (*Chem.*) $C_6H_5N(CH_3)_2$. A colourless oil boiling at 192°. It is prepared on a large scale by heating a mixture of aniline and aniline hydrochloride with methyl alcohol (free from acetone) at 230° to 270°, and fractionally distilling the product. Its hydrochloride with nitrous acid forms NITROSODIMETHYLANILINE (*see* NITROSO COMPOUNDS); with fuming sulphuric acid, dimethylaniline forms the METASULPHONIC ACID. It is largely used in the preparation of dyes; so also is its metasulphonic acid. *See* METHYL ORANGE, METHYL VIOLET, MALACHITE GREEN.

Dimidiated (*Her.*) Cut in halves, and one half removed and replaced by another half similarly treated; thus two coats are sometimes placed on one shield per pale, the half of each only appearing; *e.g.* the arms of the borough of Great Yarmouth are compounded thus.

Diminished Flier (*Join.*) A step slightly narrowed or diminished at one end.

Diminished Interval (*Music*). An interval containing one semitone less than perfect or minor.

Diminished Styles (*Join.*) The STYLES (*q.v.*) of half-glass doors or framing in which the upper part of the style is narrower than the lower part.

Diminishing Socket (*Eng., etc.*) A socket for connecting two pipes of different diameters.

Diminuendo (*Music*). Diminishing the loudness. Abbreviation, DIM. or $>$.

Diminutive (*Her.*) Similar to the "ordinary," only of smaller dimensions and having a different name; thus the "Cotise" is the diminutive of the "Bend," "Barrulet" the diminutive of the "Bar," etc.

Dimity. *See* DIAPER.

Dimmer (*Elect. Eng.*) A device for diminishing the light from electric lamps on the stage of a theatre. It consists of a variable resistance or of an IMPEDANCE or CHOKING COIL (*q.v.*)

Dimorphism (*Min., Chem.*) When a definite chemical compound crystallises in two different forms it is said to show dimorphism; *e.g.* carbonate of lime occurs in the rhombohedral form as calcite, in the rhombic form as aragonite; carbon, in the cubic form as diamond, in the hexagonal form as graphite, etc.

Dinas Clay (*Met.*) A very highly refractory fireclay used for lining metallurgical furnaces. Contains about 30 per cent. more silica and 18 per cent. less alumina than other fireclays.

Dines' Hygrometer (*Meteorol.*) *See* HYGROMETERS.

Dinitrobenzenes (*Chem.*), $C_6H_4(NO_2)_2$. There are three of these, *viz.*

NO_2	NO_2	NO_2
NO_2	NO_2	NO_2
Ortho- (or 1 : 2). M.P. 118°.	Meta- (or 1 : 3). M.P. 90°.	Para- (or 1 : 4). M.P. 173°.

Only the METADINITROBENZENE is important. It is prepared by dissolving benzene in fuming nitric acid, cooling, adding sulphuric acid, and boiling. Pour into water and crystallise from alcohol. It forms yellowish white prisms, melting at 90°. Sparingly

soluble in water, readily in alcohol. On reduction with ammonium sulphide it forms metanitraniline; reduction with tin and hydrochloric acid gives METAPHENYLENEDIAMINE (*q.v.*)

Diœcious (*Botany*). The term used when the flowers are unisexual, and the male and female flowers occur on different plants (*e.g.* willow).

Diopside (*Min.*) A greenish variety of monosymmetric pyroxene with a well marked cleavage. It usually occurs in thermo-metamorphosed marbles. *See* PYROXENE.

Dioptase (*Min.*) A hydrous silicate of copper, $CuSiO_3 . H_2O$. It crystallises in rhombohedra of an emerald green colour. It does not occur in sufficient quantity to be used as an ore of copper. From Siberia, Nassau, Chili, etc.

Diopter (*Surveying*). One of the earliest instruments for the solution of surveying problems. Invented by Hero of Alexandria (B.C. 285—224). Essentially a primitive combined theodolite and level.

Dioptric (*Light*). The unit of curvation in lenses: if r = radius of a curve in metres, then the curvature in dioptries $= \frac{1}{r}$.

Diorama. A mode of scenic representation invented by Daguerre and Bouton (1822). The pictures, which are viewed through an aperture, are translucent in parts, and the method is suitable for illustrating not only landscapes, but also interiors of buildings, clever effects being obtained by means of transmitted and reflected light, aided by screens.

Diorite (*Geol.*) An eruptive rock of deep-seated origin and of the same structure as granite, but consisting essentially of one of the plagioclase felspars, usually in association with one or more ferro-magnesian silicates, amongst which hornblende is usually present. Biotite and a small proportion of quartz usually occur as accessories. Diorite is the deep-seated or plutonic equivalent of andesite lavas and of porphyrite dykes. It grades in one direction into DIORITE GRANITE and in another into DIORITE [GA]BBRO.

Dioscoreaceæ (*Botany*). A natural order of *Dicotyledons*. The plants are natives chiefly of tropical countries, and possess large underground tubers. The tubers of the YAM (*Dioscorea*) form a valuable food.

Diota (*Archæol.*) A vessel with two ears or handles. The term is sometimes used for an AMPHORA (*q.v.*), but it applies practically to any two-handled vase.

Dip (*Elect.*) The inclination of the actual direction of the earth's magnetic force to a horizontal plane.

—— (*Eng., etc.*) (1) The amount of immersion of some object, such as the float of a paddle wheel. (2) The act of dipping work into a liquid bath, *e.g.* in galvanising iron.

—— (*Geol.*) Sedimentary rocks are deposited normally in layers which are as a whole parallel to the horizon. But subsequent disturbances may cause these to bend into folds. The amount of inclination thus caused is usually measured in degrees, counting from the horizontal. In estimating the dip of a rock it is necessary to record the direction of greatest inclination as well as its amount at the place under observation.

Dip Crank (*Eng.*) A crank formed by bending a rod to the required shape, instead of cutting the crank from a solid forging.

Diphenyl (*Chem.*), $C_6H_5 - C_6H_5$. White shining leaflets; melts at 71°; soluble in alcohol. Obtained by heating brombenzene with sodium; or better, by passing vapour of benzene through a redhot iron tube and fractionally distilling the product. Oxidised with chromic acid, it gives benzoic acid. Its chemical behaviour is very similar to that of benzene. It occurs in coal tar.

Diphenylamine (*Chem.*), $HN{<}{}^{C_6H_5}_{C_6H_5}$. Monoclinic plates; melts at 54°; soluble in alcohol, benzene, ether. Obtained by heating aniline and aniline hydrochloride for a long time at 200°, boiling the product with dilute hydrochloric acid to remove aniline, and distilling the residue. It is a weak base, its salts being decomposed by water. It unites with potassium, forming $(C_6H_5)_2NK$. Heated with chloroform in presence of aluminium or zinc chlorides, it yields ACRIDINE. It is used in the preparation of dyes; *e.g.* DIPHENYLAMINE BLUE is made by heating diphenylamine with oxalic acid, which gives CO_2.

$$3NH(C_6H_5)_2 + CO_2 = C \begin{cases} C_6H_4NHC_6H_5 \\ C_6H_4NHC_6H_5 \\ C_6H_4NC_6H_5 \end{cases} + 2H_2O.$$

See also TROPÆOLINES. A solution of diphenylamine in concentrated sulphuric acid is a very sensitive reagent for nitrites, nitrates, or chlorates, with all of which it gives a deep blue colour.

Diploïdion *or* **Diploïs** (*Archæol.*) A chiton or tunic worn by Greek women. The portion of the garment above the waist was double, and the outer fold hung loose. The term is sometimes applied to this outer fold itself.

Dip of the Horizon (*Astron., etc.*) If an observer be placed some distance above the surface of the earth, the most distant point which he can see is the extremity of a line drawn from his eye at a tangent to the earth. The angle which this line makes with a horizontal plane through the eye is called the DIP OF THE HORIZON.

Dippel's Oil. BONE OIL (*q.v.*)

Dipping (*Pot.*) The process of immersing the bisque ware in the liquid glaze, which is melted upon the ware subsequently in the glost oven.

—— (*Chem. Eng.*) Immersion in an acid bath prior to electroplating or galvanising.

Dip Pipe (*Gas Manufac.*) *See* GAS MANUFACTURE.

Dipropargyl (*Chem.*), $CH \vdots C . CH_2 . CH_2 . C \vdots CH$. A mobile liquid with penetrating odour, and boiling at 85°. It is isomeric with benzene, C_6H_6, but differs from it by the ease with which it polymerises, combines with bromine, and undergoes oxidation.

Dipteral (*Architect.*) A temple which has two rows of columns on each of its long sides. *See also* PSEUDO-DIPTERAL.

Dipterocarpaceæ (*Botany*). A dicotyledon order belonging to India. The trees all contain resin, and yield many economic products. *See* CAMPHOR.

Diptych (*Archæol.*) (1) A tablet consisting of two leaves connected by hinges, generally made of metal, wood, or ivory. The inner surfaces were covered with wax, and upon these the ancients wrote with a stylus. (2) The ornate tablets distributed by the consuls to commemorate their tenure of office, and

bearing their names and portraits. (3) A public register or list of the names of consuls and other magistrates.

Diptych (*Ecclesiastical*). (1) A register of martyrs, bishops, and other orthodox persons, living or dead, mentioned in the prayers of the Church. (2) The intercessions in the course of which the names were mentioned.

—— (*Art*). A painting or other work of art, generally an altarpiece, in the form above described. *See* TRIPTYCH.

Direct (*Music*). A mark (*w*) placed at the end of a stave on a line or space to indicate the note in the following corresponding stave.

Direct Cotton Dyes. *See* DYES AND DYEING.

Direct Process (*Met.*) The production of wrought iron (or steel) from the ore without the usual intermediate stage in which cast iron is produced.

Direct Spokes (*Cycles*). Those which are radial to the axis of the wheel. *Cf.* TANGENT SPOKES.

Direct Vision Spectroscope (*Phys.*) *See* SPECTROSCOPE.

Dirk (*Armour*). (1) A dagger or poniard formerly used by Highlanders and still worn as part of a Highland costume. (2) The small sword formerly worn by junior naval officers.

Dirty Proof (*Typog.*) Proof sheet having many corrections, owing to mistakes in composition.

Di-saccharides (*Chem.*) *See* CARBOHYDRATES.

Disc *or* **Disk.** (1) A flat thin circular plate of any material. (2) In body armour a plate of metal for protecting the body at certain joints of the armour: a ROUNDEL. (3) The surface of the sun, moon, or a planet as it appears projected in the heavens. *See* DISCUS.

Disc Armature (*Elect. Eng.*) *See* ARMATURES.

Disc Crank (*Eng.*) A crank formed by a disc of metal keyed on the crank shaft. The crank pin is fixed near its periphery. It is simpler to make and more easy to balance than an ordinary crank. In many petrol motors the pair of flywheels forms the disc crank. *See* PETROL ENGINES.

Discharge (*Eng.*) (1) Liquid flowing from a pump, etc. (2) The rate of flow of the same liquid; that is, the amount passing in a given unit of time (minute or second, etc.)

——, **Electric.** In general, the loss of charge by electrified bodies, or the flow of electricity along any path, but tacitly limited to those cases in which a dielectric forms part of the circuit, and the discharge therefore becomes more or less disruptive, giving visible phenomena, such as a brushlike glow, succession of sparks, vacuum tube effects, etc.

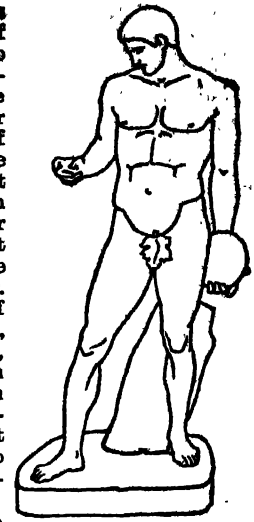
Discharge Valve (*Eng.*) A valve through which the DISCHARGE (*q.v.*) leaves a pump: used in steamships to permit the CIRCULATING WATER to escape.

Discharging Arch (*Build.*) An arch built over a LINTEL (*q.v.*) to relieve it of the weight above.

Discobolus (*Class. Antiq.*) A thrower of the DISCUS or quoit. The term is applied also to a statue representing a man in the act of throwing the discus. It was a favourite subject with ancient sculptors, and there are several admirable statues extant.

Discolouring (*Dec.*) A defect in enamelled work (*q.v.*), in which white enamel becomes somewhat yellow, due to either an improper selection of white pigment or driers used in the manufacture of the enamel. The defect cannot be remedied.

Disconnecting Traps (*Hygiene*). The purpose of a disconnecting trap is to prevent free communication between the air of the public sewer and the air of the house system of drainage. It should be fixed at a point as distant as may be practicable from the building, and as near as practicable to the point at which the drain may be connected with the sewer. The trap should be self cleansing, not too large, free from all mechanism, and provided with an efficient "seal." To obtain access for inspection purposes it is desirable that the disconnecting trap should be fixed in a manhole.



DISCOBOLUS OF NAUCYDES, NAPLES.

Disconnector (*Build.*) *See* DISCONNECTING TRAP.

Discord (*Music*). A chord requiring resolution and often preparation. Discordant intervals are all intervals, except those given as CONCORDANT (*q.v.*) *Also called* DISSONANCES.

Disc Piles (*Civil Eng.*) Piles (*q.v.*) in the form of a hollow tube of cast iron, furnished with a broad flange forming a foot at the lower end; used in sandy ground. The sinking is accomplished by scouring out the sand under the foot by means of a jet of water under pressure, which is forced through a pipe running down the inside of the pile.

Discs of Armature Cores (*Elect. Eng.*) Thin sheet iron of the best quality (*e.g.* Swedish charcoal iron), from ·04 to ·08 in. thick, is stamped into discs of suitable form for building up the armature cores of dynamos and motors.

Discus (*Archæol.*) A disc, generally of metal, used in ancient Greek and Roman athletic games. *See* DISCOBOLUS.

Disc Valve (*Eng.*) Usually a disc of rubber, fastened down by a bolt through the centre on a flat seat containing perforations. Liquid can rise through these openings, the disc of rubber lifting and thus providing a passage.

Disc Wheel (*Eng.*) A wheel without any radial arms: it may have a thickened boss and rim, or be of uniform thickness.

Disengaging Gear (*Eng.*) Levers, etc., for operating CLUTCHES (*q.v.*)

Dished (*Carp.*) A hole in a board is said to be dished when the edge is bevelled.

Dishing (*Eng., etc.*) A formation often given to wheels and discs in which the centre lies out of the plane of the rim; greater stiffness is gained by using this form.

Disinfectants (*Hygiene*). Substances capable of destroying the specific organisms which cause disease. Their mode of action may be either physical or chemical. Belonging to the former class is heat, which is the best disinfectant, especially moist heat. Among the chemical disinfectants are perchloride of mercury (corrosive sublimate), formalin, carbolic

acid (phenol), sulphur dioxide. Disinfectants, to be effectual, must be of sufficient strength and thoroughly applied to the articles or rooms undergoing disinfection. *See* SANITATION.

Disintegrators (*Chem. Eng., etc.*) Machines for grinding dry substances. Most modern types do not grind, but disintegrate by concussion; *i.e.* two concentric discs with projecting steel arms or "beaters" are rotated in opposite directions in a beating chamber or casing, into the top or side of which the material to be pulverised is fed. There are many variants of this type, differing mainly in the disposition and driving of the beaters.

Dispersion (*Light*). The splitting up of a beam of white light (or other composite light) into its component colours by some method depending upon the variation in the refractive indices of the latter. *See* SPECTRUM.

——, **Anomalous.** Some substances used as prisms produce a dispersion in which the order of wave lengths is not the same as that produced by a glass prism; *e.g.* a solution of fuchsine deviates red light more than violet. These anomalous effects are always dependent upon the existence of absorption. Thus light waves falling upon a glass prism probably set the molecules in vibration, but as their natural period does not coincide with that of any of the visible waves of light, the result is a forced vibration of small amplitude, and very little light is absorbed. But if the natural period of some constituent of the prism is the same as that of some wave length in the incident light, then the result is "resonance," and that particular wave length is absorbed; *i.e.* the refractive index for it becomes infinite, and an absorption band is produced in the spectrum. It is only natural to expect that abnormal effects should occur for those wave lengths which are just too great or just too small to give resonance, and as a matter of fact experiment and theory show that the refractive index is abnormally increased for those wave lengths which are just too great, and abnormally diminished for those wave lengths which are just too small. Hence the order of colours is changed. These effects are somewhat difficult to observe, as they are generally produced by strongly coloured substances, which necessitate the use of prisms of very small refracting angle.

Displacement (*Mech.*) The amount a body has been moved from any given position.

—— (*Eng.*) The space swept through by a piston in each stroke: it equals the area of piston multiplied by the length of stroke.

Displacement Cylinder (*Eng.*) An auxiliary cylinder (used in certain forms of gas engine) in which the charge (*q.v.*) is compressed previous to entering the working cylinder. *See also* GAS ENGINES.

Displacer Piston (*Eng.*) A piston occasionally used in gas engines for driving out the burnt gases from the working cylinder.

Displayed (*Her.*) The wings of birds of prey are "displayed" when they appear spread or expanded; for other birds' wings so expanded the term is "disclosed."

Display Work (*Typog.*) Type displayed or not set solid, as in JOBBING WORK (*q.v.*), titles, heads, etc. The object is to attract attention.

Disposition (*Paint., etc.*) The judicious arrangement of figures, etc., in a picture, or of the several parts in a building.

Dissipation of Energy (*Phys.*) The process by which the total amount of available energy is continually being diminished. For example, when fuel is burnt to work an engine, the rejected heat, or heat which is not converted into work, is allowed to escape; and though it may contribute to the raising of the temperature of the air, or of neighbouring objects, it cannot be recovered and utilised. It has not been destroyed, but it has ceased to be available.

Dissociation (*Phys., Chem.*) When certain substances are placed under suitable conditions of temperature or pressure or solution, the molecules composing them are resolved into simpler molecules, atoms, or ions; and when the original conditions are restored the original substances are reproduced. This phenomenon is called dissociation. If ammonium chloride (not absolutely dry) be heated, its vapour is found to weigh half as heavy as we should expect it to do if it consisted of molecules of the formula NH_4Cl, but exactly what we should expect if it consisted of equal numbers of molecules of ammonia and hydrochloric acid gas, formed by the decomposition of the ammonium chloride according to the equation $NH_4Cl = NH_3 + HCl$. When the vapour is cooled the ammonium chloride is reproduced. In the state of vapour, therefore, ammonium chloride is dissociated. Examples of substances which undergo a like change are: Iodine at 1500°, $I_2 = I + I$; phosphorus at 1750°, $P_4 = P_2 + P_2$; hydriodic acid, $2HI = H_2 + I_2$, above 150°; nitrogen peroxide, $N_2O_4 = NO_2 + NO_2$; and many others. At a given temperature each gaseous product of dissociation exerts a definite pressure called the DISSOCIATION PRESSURE; if at this temperature the pressure of a constituent be increased and kept above the dissociation pressure, the original substance will be reproduced and no dissociation will be possible. Salts of weak acids and bases undergo dissociation in a precisely similar manner on solution in water. Any acid, base, or salt whose solution in water is a conductor of electricity undergoes ELECTROLYTIC DISSOCIATION when dissolved in water. For example, common salt (NaCl), when dissolved in water, is resolved to an extent depending on the strength of the solution into the ions (*see* IONS) $\overset{+}{Na}$ and $\overset{-}{Cl}$. The undissociated part and the ions obey the law of mass action (*see* MASS ACTION), so that if the quantity of salt be put = 1, and the dissociated part = a, and the volume of the solution containing one gram molecule v, we have $k = \dfrac{\frac{a^2}{v^2}}{\frac{1-a}{v}}$.

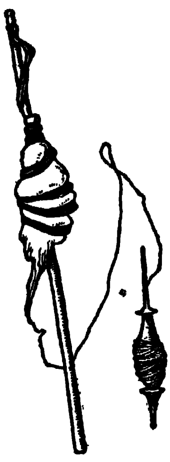
Where k is a constant depending on the nature of the dissolved substance, it is called the DISSOCIATION CONSTANT for the particular substance.

Dissociation Coefficient (*Elect.*) *See* IONISATION COEFFICIENT.

Dissolving Lantern *or* **Dissolving Views.** The exhibition of slides in such a manner that one view fades away and another gradually becomes visible. This is effected by the use of two (or more) lanterns focussed simultaneously on the screen. The light from one is gradually obscured, either by interposing an opaque screen or by turning off the supply of oxygen gas; this causes the image of the slide to fade away, and meanwhile the reverse process is gone through with the second lantern, and the image produced by it grows in intensity till the full amount of brilliancy is attained.

Dissonance (*Sound*). The effect produced by two notes whose frequencies are such as to produce BEATS (*q.v.*) Also termed a DISCORD (*q.v.*) in music.

Distaff (*Archæol.*) A staff about 3 ft. long, round one end of which flax or wool for spinning was wound. The ancients used a cane, split at one end and formed into a receptacle for the material to be spun. In spinning, the distaff was held under the left arm, the wool or flax being drawn from it through the fingers of the left hand, and twisted spirally by the thumb and forefinger of the right hand. The operation was aided by a spindle attached to the end of the thread, and which hung down. When the spindle touched the floor the length of thread was wound round it, and the operation repeated. In Art the distaff is sometimes employed as a symbol of the female sex and female authority. *See* COTTON, LINEN, SILK, WOOLLEN MANUFACTURE.



DISTAFF AND SPINDLE.

Distance (*Paint.*) The effect obtained by contrasting the darker tones and richer colours in the foreground of a picture with the lighter tones and more delicate colours beyond; and by maintaining the correct diminution of scale—in accordance with the laws of perspective—in the objects represented as they recede from the eye. In a landscape the distance and middle distance are the parts of the composition which are not occupied by foreground or sky; they are assumed to be comparatively remote from the observer.

Distance of Visible Horizon or Offing (*Astron.*) *See* OFFING.

Distemper (*Dec.*) A water paint used principally for plaster and stucco work, and made by mixing whiting (*q.v.*) with water and some adhesive substance such as size, and with or without the addition of colour. Distempering is the cheapest process of painting; it is free from gloss, and capable of giving very artistic effects. Scenic artists use distemper almost exclusively, while all wallpapers excepting those known as SANITARIES (*q.v.*) are printed in distemper colours. On ordinary walls and ceilings distemper is applied over a coat of claircolle (*q.v.*) Only one coat is given, and this must be applied quite evenly, so as to avoid patches. Some colours cannot be used in distemper, as the lime in the plaster destroys them. The following is a list of the colours which may safely be employed, and from them can be obtained any shade, tint, or hue, including black and white:—*Whites:* Barytes, blanc fixe, whiting, satin white, zinc oxide, lithopone, Orr's white, gypsum, terra alba, china clay. *Colours:* Yellow ochre, sienna, umber, Vandyke brown, cadmium yellow, vermilion, red lead, red oxide, red ochre, Venetian red, Indian red, light red, ultramarine, cobalt blue, chrome green, cobalt green, emerald green, malachite green, and all black pigments. During the past few years washable distempers have increased in use very considerably. They are made in a large variety of permanent colours, and in some cases may be applied to wood and varnished over.

Distemper or **Tempera** (*Paint.*) (1) A method of painting in which opaque colours are used mixed with water and with some glutinous substance soluble in water—*e.g.* size, yolk or white of egg, etc. The painting is executed upon a ground of chalk or dry plaster (*gesso*), which is generally spread upon wood, but sometimes upon canvas. This method is to be distinguished from *fresco*, in which the colours are applied to a fresh and moist surface of plaster. (2) The term is applied likewise to the pigments used in this process. *See* PAINTING, METHODS OF.

Distillation (*Phys.*, *Chem.*) The process of heating a substance in a vessel until it boils, conducting its vapour into a cooling arrangement called a condenser, and collecting the condensed vapour in a receiver. The object of such a process is: (1) To separate a liquid from any dissolved solid it may contain; *e.g.* when tap water is distilled the solids, such as calcium carbonate, which it contains are left in the still, and very nearly pure water is obtained in the receiver. (2) To separate a more volatile liquid from a less volatile. (3) To separate a volatile product obtained in a chemical reaction from other less volatile products; *e.g.* when potassium nitrate is distilled with sulphuric acid, nitric acid is produced, and, being more volatile than any other substance present, it distils over alone at a moderate temperature. As the boiling point of a liquid depends on the atmospheric pressure, and some liquids undergo decomposition at their boiling points, it is necessary to distil such liquids under reduced pressure. This is done by connecting the receiver to some form of air pump, so as to reduce the pressure in the apparatus to the desired degree; *e.g.* lævulinic acid boils with decomposition at 239° under ordinary pressure, but under 12 mm. it distils unchanged at 144°. In some cases it is possible to separate a mixture of two liquids of different boiling points by a process of FRACTIONAL DISTILLATION. In this process the distillate is collected in fractions as the boiling point of the mixture rises. Suppose we have a mixture of equal parts of benzene (B.P. 81°) and toluene (B.P. 110°); collect fractions every 5° from 80 up to 110°; now redistil fraction 1 (80 to 85°), most of it passes over below 85°. At 85° add fraction 2 (85 to 90°), and again distil; some will pass over below 85°, and is collected in 80 to 85° receiver. Now change receiver and collect 85 to 90° fraction, and so on. After three or four operations it will be found that the lowest and highest fractions are much the greatest, and consist of benzene and toluene respectively. Numerous organic liquids placed in water and submitted to the action of a current of steam from boiling water will distil over with the steam, even though the liquid have a much higher boiling point than water. This is called DISTILLATION IN STEAM. A very important instance of this is found in the preparation of aniline (*q.v.*), where the aniline has to be separated from a solution of sodium stannate and sodium chloride by distillation in a current of steam. DESTRUCTIVE DISTILLATION is simply heating a substance out of air so as to decompose it and collect the products of decomposition. The preparation of coal gas and coal tar is an example of destructive distillation.

Distillation in Steam (*Chem.*) *See* DISTILLATION.

Distortion (*Astron.*) The change of shape of the sun and moon when near the horizon owing to differential refraction of the upper and lower limbs.

—— (*Photo.*) The production of an image of incorrect form, due to the SPHERICAL ABERRATION (*q.v.*) of the lens, tilting of the camera, etc.

Distress (*Eng.*) Excessive strain in a structure, caused by undue loading.

Distribute (*Typog.*) To replace type (after printing) in the case, each letter, etc., being returned to its proper compartment, ready for resetting.

Distributed Load (*Eng., etc.*) A load which is spread out over the whole of a beam or other member of a structure. A wall carried by a girder is an example: the weight of the wall is spread out over the whole of the girder.

Distyle (*Architect.*) Having two columns. The simplest form of Greek temple is known as DISTYLE-IN-ANTIS. In this form of temple there are two columns between the antæ. *See* ANTA, TETRASTYLE, DECASTYLE, HEXASTYLE, *and* OCTASTYLE.

Ditriglyph (*Architect.*) An arrangement of the Doric frieze and intercolumniation so that two triglyphs are obtained between those immediately above two adjacent columns. This necessitates a wider intercolumniation than the usual arrangement, in which there is only one triglyph over the space between two columns. *See* TRIGLYPH; ARCHITECTURE, ORDERS OF; ENTABLATURE; MONOTRIGLYPH; *and* TRITRIGLYPH.

Diurnal Range (*Meteorol.*) Applied to the changes which occur during the day (twenty-four hours) in temperature, atmospheric pressure, etc.

Divalent Elements (*Chem.*) *See* VALENCY.

Divided Bearing (*Eng.*) A BEARING (*q.v.*) in which the BUSH, or part which provides the actual bearing surface, is divided into two (or occasionally more) parts. These parts can be adjusted to take up wear, as in the common PLUMMER BLOCK (*q.v.*)

Divided Pitch (*Eng.*) The distance from one thread to the next in a multiple-threaded screw If there are n threads of pitch l, the divided pitch
l

Dividers. Compasses used solely for measuring off distances. They are often provided with a screw adjustment.

Dividing Engine (*Phys., Eng., etc.*) A machine for ruling scales. The subdivision of the fundamental measurements usually depends on an accurately cut screw furnished with a graduated head.

Divi-divi (*Botany*). A valuable tanning material consisting of the pods of *Cæsalpinia coriaria* (order, *Leguminosæ*), which are very rich in tannin. *See also* DYES AND DYEING.

Divinity Calf (*Binding*). Dark brown calf, finished in blind tooling or antique. So called from its use being almost limited to theological books.

Divisi, Divided (*Music*). An orchestral term implying that the instruments playing the part so marked are to divide into firsts and seconds.

Division Peg *or* **Point** (*Eng.*) The peg which holds a DIVISION PLATE (*q.v.*) at rest in any required position.

Division Plate (*Eng.*) In lathes for ornamental and special work a plate is fixed on the mandrel and divided into a convenient number of parts by rows of holes arranged in concentric circles. The mandrel can then be turned through a definite fraction of a revolution and fixed by means of a pin, termed the DIVISION PEG, thus enabling drilling, etc., to be carried out on the work at definite points round its circumference. The work remains fixed, and is acted on by the drill, milling cutter, etc., which may be driven from an OVERHEAD MOTION (*q.v.*) The number of holes in the various rows varies. A good set should include 96, 100, and 360, with some number of which seven is a factor. Others may be added if the plate be large enough.

Do (*Music*). The sol-fa syllable for C.

Dobbie *or* **Dobby** (*Cotton Weaving*). A machine which takes the place of a tappet, and produces more elaborate weaves. Its capacity for pattern production is also much greater. There are numerous types, some of which are positive and others negative in their action. The following are the chief: Ward's, Keighley, Blackburn, Burnley, Dobcross, Catlow.

—— (*Silk Manufac.*) A small machine placed at the top of power loom, for raising and depressing the HEDDLES (*q.v.*) according to the tie arranged upon it. Used only for plain fabrics such as twills, satins, checks, etc.

Dock Gates (*Civil Eng.*) Watertight doors of wood and metal, generally made in two parts which are hinged at the outer edge, and provided with sluices. They are usually operated by hydraulic power. To enable the gates to withstand the pressure of the water, they are so hung that they meet each other at an angle when closed, the apex of the angle being directed inwards, *i.e.* towards the side on which the water is highest. The greater the pressure of water the greater the force with which the gates are kept closed. They can only be opened when the level of the water is the same (or very nearly so) on both sides of the gates.

Docks (*Civil Eng.*) Enclosed spaces for the accommodation of ships; they communicate with the water in the outside channel by means of DOCK GATES (*q.v.*) Instead of opening directly to the channel, these gates may open into a tidal basin (*q.v.*) If a dock can be emptied of water to permit of repairs to the ship's hull, it is termed a DRY DOCK.

Dock Walls (*Civil Eng.*) Massive walls of concrete or masonry; a space between the wall and the ground behind is usually excavated, and filled in with hard material, well rammed in. If the ground below is treacherous, the foundations of the walls may rest on PILES.

Doctor. The technical name for a copper soldering iron or bit.

—— (*Chem. Eng.*) The scraper attached to the last roller of a plodding machine (*q.v.*), which removes the soap in strips or ribbons.

—— (*Paper Manufac.*) A flat iron bar used for keeping PRESS ROLLS and DRYING CYLINDERS free from small fragments of paper.

Dodder (*Botany*). *Cuscuta*. A genus of the order *Convolvulaceæ*, which have become parasitic on many plants. They are leafless and rootless, and do much damage to their hosts.

Doeskin (*Woollen Manufac.*) Fine woollen cloth with fibrous face, the weave being five or eight end sateen or doeskin. It is the reverse of the buckskin (*q.v.*) both as regards twill effect and finish.

Doffer (*Textile Manufac.*) A wire-covered cylinder or drum (about 24 in. diameter) on carder at the opposite end to licker-in, which collects the carded fibres from the large cylinder in the form of a thin sheet or WEB, prior to being contracted into a SLIVER

(*q.v.*) Also applied to the attendant who "doffs" the full bobbins on fly and spinning frames, and replaces with empties.

Doffing (*Textile Manufac.*) The process of removing the material in carding, and also in removing the yarn from the spindle in spinning.

Dogfish (*Zoology*). The flesh of the dogfish (*Scyllium canicula*; family, *Scyllidæ*) is used as food in a fresh or dried state. The skin forms a kind of shagreen, used in wood polishing.

Dog Legged Stairs (*Join.*) Stairs which have the outside strings vertically above each other.

Dogs (*Carp., etc.*) Iron cramps used for drawing up glued joints.

—— (*Eng.*) (1) The jaws of a chuck or similar device for holding work. (2) A lathe CARRIER (*q.v.*)

Dog's Ear (*Plumb.*) The corners of a lead tray turned into a fold.

Dog's Tooth (*Build.*) Bricks laid with one corner projecting, in a brick cornice.

Dog-tooth (*Architect.*) The characteristic ornament of the Early English style, generally used in a hollow moulding. *See* TOOTH ORNAMENT.

Dog Wheel (*Eng.*) A RATCHET WHEEL (*q.v.*)

Doh (*Music*). The first degree or note of the scale in the MOVABLE DOH or TONIC SOLFA system.

Dolabra, *dimin.* **Dolabella** (*Archæol.*) A cutting instrument: chisel, celt, axe, varying in shape according to the purpose for which it was used. Ornate dolabræ were used by the pontifices for slaughtering the sacrifices. Caxton refers to the dolabre (adze) as the trademark of carpenters.

Dolce (*Music*). Sweetly.

Doldrums (*Met.*) The equatorial region of calms between the surface winds of the two hemispheres. The position of this region varies a little, but it is a little to the north of the terrestrial equator.

Dolente, Con Dolore (*Music*). Sorrowfully.

Dolerite (*Geol.*) An intrusive rock of basic composition, in which a glassy or lithoidal ground mass is either absent or occurs only in small quantity. The structure is ophitic; *i.e.* the felspars, which have been formed at an early stage, are enveloped within the (later formed) pyroxene. The essential constituent minerals are: (1) LABRADORITE, usually in lath shaped crystals; (2) a PYROXENE enclosing them; (3) some ILMENITE; and (4) commonly some OLIVINE. The rock never occurs as a lava, but usually either as a sill or a dyke.

Dolium (*Archæol.*) A large earthenware jar, spherical in shape, used by the Romans for holding wine, oil, corn, etc. Vessels of this character are in use in India at the present day.

Dolly (*Cycle Manufac., etc.*) A soft mop, rotated at a high speed on a polishing head, for putting the final polish on work to be plated.

—— (*Eng.*) The tool used for holding up the head of a rivet while closing or riveting up.

—— (*Mining*). A heavy tool (often of wood) used for crushing minerals.

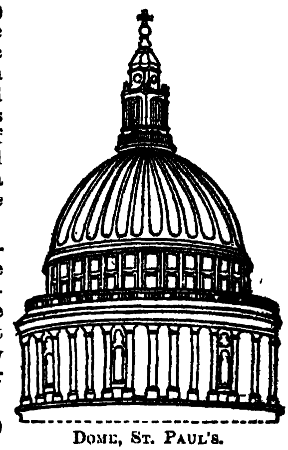
Dolmen (*Archæol.*) A French name for a prehistoric structure consisting of two parallel rows of upright stones with large flat stones placed horizontally across them, forming a passage: a CROMLECH. *See* PREHISTORIC ARCHITECTURE.

Dolomite (*Min.*) Calcium magnesium carbonate, $CaMg(CO_3)_2$. It occurs in rhombohedral crystals, the faces of which are usually curved; colour white, yellow, pink, brown, to almost black. Also massive (MAGNESIAN LIMESTONE). Does not effervesce with 20 per cent. hydrochloric acid in the cold, but does when warmed in it. Iron may replace the other bases to almost any extent; the darker and more curved specimens usually contain the greater amount of iron. A limestone that has been dolomitised is of less bulk than the original, and often shows peculiar structures due to molecular rearrangement. Magnesian limestone is a good building stone, as it is so slowly affected by weathering. Some of the massive varieties are used in making hydraulic cement. Its distribution is very wide.

Dolphin (*Art., etc.*) (1) A conventional figure of a species of cetaceous mammal, having a large head. They are especially used as decorations on fountains. (2) In heraldry they are represented with the bodies bent in a semicircle. (3) A French gold coin at one time current in Scotland.

—— (*Zoology*). The dolphins and porpoises belong to the family *Delphinidæ* of the mammalian order *Cetacea*. Many species—for example, the bottle-nosed dolphin of America—yield a valuable oil.

Dome (*Architect.*) The cupola was one of the characteristic features of the Italian *duomo* (cathedral), and the term dome was taken from the name of the building, and used to denote the cupola type of roof. *See* CUPOLA.



DOME, ST. PAUL'S.

—— (*Eng.*) A dome-shaped chamber on the head of a boiler, supposed to increase the steam space and collect dry steam. Is gradually being discarded in favour of a DRY PIPE (*q.v.*)

Domeykite (*Min.*) Arsenide of copper, Cu_3As_2. Copper = 71·63, arsenic = 28·57 per cent. It occurs in tin white octahedra. More often in reniform masses. It occurs at Coquimbo and at Copiapo in Chili.

Dominant (*Music*). The technical name of the fifth note of a scale. Its frequency is one and a half times that of the KEYNOTE (*q.v.*)

Dominant Tone (*Paint.*) A term used to describe the principal or predominating colour or tone in a picture.

Dongola Leather. Goatskins tanned by a combination of vegetable and mineral tanning agents, as alum and salt followed by gambier or other vegetable tan, or chrome salts followed by vegetable tan; or, *vice versa*, vegetable tan followed by alum or chrome. Dongola leather is now made from calf, sheep, and split hide, as well as goat.

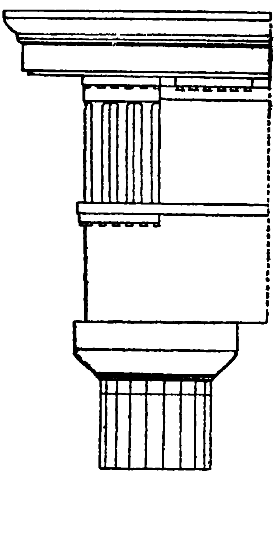
Donjon (*Archæol.*) The principal tower or innermost keep of a castle, usually built on a natural or artificial mound. It served as the last retreat of the garrison in case of necessity, its lower part being used as a prison. Known also as the KEEP, DONJON KEEP, TOWER.

Donkey Engine (*Eng.*) A small auxiliary engine used to drive the feed pumps, circulating pumps, and other subsidiary machinery on a steamship.

Doppler's Principle (*Phys.*) When there is any relative motion between a source of sound and a listener, the number of waves received per second is different from that corresponding to the actual frequency of the source, and hence the apparent pitch is altered, being increased for motions of approach and diminished for motions of recession. If V = velocity of sound, v_s = velocity of source, v_1 = velocity of listener, n — actual frequency of source, then the apparent frequency is $n \times \left(\frac{V \pm v_s}{V \mp v_1}\right)$, the upper signs signifying approach. The principle has only theoretical interest in the case of sound, but it is true for wave motion generally, and its application to light has been of the highest importance, as it enables the velocity of stars and other heavenly bodies in the line of sight to be measured by the displacement of their spectral lines.

Dorian (*Music*). *See* MODES.

Doric Order (*Architect.*) The earliest and most severe of the orders used by the Greeks. *See* ARCHITECTURE, ORDERS OF.



DORIC-GREEK, TEMPLE OF THESEUS, ATHENS.

Dormer Window (*Architect.*) A vertical window formed in and projecting above the surface of a sloping roof. The rooms which receive light from windows of this form are usually sleeping apartments; hence the name.

Dornick (*Textiles*). *See* DIAPER.

Dorsed (*Her.*) *See* AVERSANT.

Dorse, Dorsel, Dossal, Dossel, Dosser (*Furniture*). (1) Ornamental cloth, frequently tapestry, hung at the back of a seat, or used to cover the back of a chair, especially a throne or chair of State, or forming a canopy or curtain at the back of such a seat. (2) An ornamental cloth, usually embroidered, hung at the back of the altar or at the sides of the chancel. (3) Hangings placed round a hall or on the walls of a room of State. (4) In some churches the backs of stalls are ornamented with carvings in imitation of such hangings. *See* LINEN FOLD.

Dot (*Music*). (1) Placed after a note or rest, it adds one half the value to the note or rest. Each succeeding dot is one half the value of the preceding dot. (2) Placed over or under a note, it makes that note half note half rest. *See* STACCATO. Two dots placed at a double bar (:‖ or ‖:) show that the section on the side of the dots is to be repeated.

Dot (*Plastering.*) A small dab of plaster to serve as a guide for the rule in forming a SCREED (*q.v.*)

Doublé (*Binding*). A style introduced from France, in which coloured morocco leather is used on the insides of the cover instead of board papers. The insides are elaborately finished, frequently with a dentelle (*q.v.*) border, while the outside is comparatively plain, with only a few lines in blind tooling.

Double Acting Engine (*Eng.*) An engine in which the steam (or gas) acts on each side of the piston alternately. All modern steam engines were of this type till the introduction of very high speed steam engines for coupling direct to dynamos led to the revival of SINGLE ACTING ENGINES (*q.v.*)

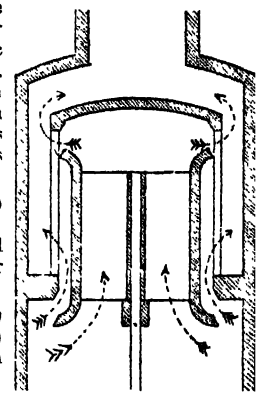
Double Acting Pump (*Eng.*) A pump in which the piston is forcing water on one side while drawing water into its cylinder or barrel at the other; in the return stroke the process is reversed. Such a pump requires valves working in a manner similar to that of a steam engine; they must, however, remain open right to the end of the stroke.

Double Acting Steam Hammer (*Eng.*) A STEAM HAMMER (*q.v.*) in which steam can be used above the piston to intensify the blow.

Double Bar (*Music*). Two perpendicular lines across the stave showing the end of a movement or section.

Double Bass. *See* MUSICAL INSTRUMENTS: STRING (BY BOW).

Double Beat Valve (*Eng.*) A valve of circular plan, with two concentric seating faces. *See* FIGURE. The pressure on this form of valve is much less than in the common lift valves or slide valves, and it is easier to move.



DOUBLE BEAT VALVE.

Double Belting (*Eng.*) Two thicknesses of leather sewn or otherwise fastened together to give greater strength.

Double Broad (*Typog.*) Furniture double the width of broad, *i.e.* eight picas in width.

Double Butted Spokes (*Cycles*). Spokes with the ends thicker than the central portion, for the purpose of making the joint with rims and hubs stronger.

Double Butt Joint (*Eng.*) A butt joint with covering strips on each side; the rivets go through three thicknesses of metal.

Double Cases (*Typog.*) Cases specially made for small jobbing founts, the upper and lower cases being made in one.

Double Cone Moulding (*Architect.*) A Norman enriched moulding, consisting of a series of truncated cones placed end to end.

Double Contraction (*Pattern Making*). When IRON PATTERNS (*q.v.*) are used, the original wooden pattern from which the iron pattern was cast must have all allowances for contraction doubled, as the iron pattern itself must have the ordinary contraction allowance (*i.e.* must be larger than the final casting) in order to give the proper dimensions to the latter.

Double Crown. The size of a printing paper which measures 30 by 20 in.

Double Cut File (*Eng.*) The ordinary form of file, which has two sets of teeth, one crossing the other.

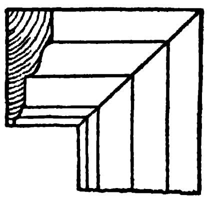
Double Cylinder Engine (*Eng.*) An engine having two cylinders acting on the same crank shaft.

Double Demy. The size of a printing paper which measures 35 by 22½ in.

Double Driver Chuck (*Eng.*) A DRIVER (*q.v.*) with two pins, which act on each end of the carrier at once.

Double Ended Boiler (*Eng.*) A boiler with a fire-box at each end : used in marine practice.

Double Ended Bolt (*Eng.*) A bolt with no head, but with a thread at each end on which a nut is screwed.



DOUBLE FACED ARCHITRAVE.

Double Faced Architrave (*Join.*) A moulding round a door or window opening with two plane faces, one sunk below the other.

Double Faced Hammer (*Eng.*) *See* HAMMERS.

Double Faced Skirting (*Join.*) A form of skirting (*q.v.*) built in two parts, the lower part projecting in front of the upper part.

Double Fagoted Iron (*Eng.*) Iron which has been put through the operation of fagoting (*q.v.*) twice over.

Double Flat (*Music*), (♭♭). A sign which lowers a note a whole tone.

Double Flemish (*Build.*) Flemish bond showing on both sides of the wall. *See* FLEMISH BOND.

Double Floor (*Carp.*) A double floor consists of BINDERS, CEILING JOISTS, BRIDGING JOISTS, and FLOOR BOARDS (*q.v.*) *See also* FLOORS.

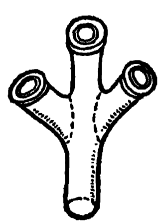
Double Flued Boiler (*Eng.*) A LANCASHIRE BOILER. *See* BOILERS.

Double Foolscap. A size of paper. In printing paper, 27 by 17 in.; and in writing paper, 26½ by 16⅝ in.

Double Frame (*Typog.*) A composing frame usually made of deal and holding two pairs of cases at the same time. *See* CASE.

Double Gearing (*Eng.*) A train of wheels containing two pinions and two wheels. The BACKGEAR (*q.v.*) of a lathe is an example.

Double Headed Rail (*Civil Eng.*) The form of rail now used in most permanent ways; it can be reversed when worn, as the top and bottom are of the same cross section.



DOUBLE JUNCTION.

Double Hung (*Join.*) Sashes that are hung with cords and weights.

Double Imperial. The size of a printing paper measuring 44 by 30 in.

Double Junction (*Build.*) A pipe with a branch on each side of it.

Double Lath (*Build.*) A strip of wood ⅜ in. thick.

Double Letters (*Typog.*) Old face letters such as ct, ft, and diphthongs Æ, Œ, æ, œ, etc.

Double Margin Door (*Join.*) Where it is inconvenient to have folding doors, and the opening is too wide for a well proportioned door, a door is constructed with four styles, with a bead down the centre to make it look like a pair of folding doors.

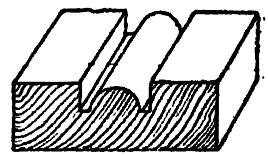
Double Narrow (*Typog.*) Furniture double the width of a narrow, *i.e.* six picas in width.

Double Pica (*Typog.*) A fount two small picas in depth, and in size between paragon and two line pica. *See* TYPE.

Double Ported D Slide Valve (*Eng.*) A special form of SLIDE VALVE (*q.v.*) intended to facilitate the escape of the exhaust steam by means of ports in the valve itself, which has a hollow cast in it of the form of a capital D.

Double Post. A size of printing paper usually 32 by 20 in.

Double Pott. A size of printing paper which measures 25 by 15 in.



DOUBLE QUIRKED BEAD.

Double Quirked Bead (*Join.*) A bead with two quirks (*q.v.*).

Double Refraction (*Phys.*) A doubly refracting body is one in which the velocity of light is different in different directions, instead of being independent of direction, as in glass or water. Singly refracting substances like glass may, however, be made doubly refracting by setting up internal stresses, by pressure, or by unequal expansion. This variability of light-velocity with direction implies the existence of definite molecular structure. It occurs in all crystals except those belonging to the cubic system. Every such substance has one direction (UNIAXAL CRYSTALS), and many two directions (BIAXAL CRYSTALS), along which they behave to light as singly refracting substances, possessing a definite refractive index (called the ORDINARY INDEX). This direction is called an OPTIC AXIS, and the two extremes of light-velocity occur for vibrations executed at right angles to the optic axis and along the optic axis respectively. The former velocity is the greater in "positive," and the latter in "negative" substances. When light passes through the substance in any direction other than along an optic axis, it may be regarded as consisting of two portions, one executing its vibrations perpendicular to the axis and having a constant velocity and index (the ORDINARY RAY), and another whose vibrations are at right angles to the former, and whose velocity, and therefore index, depends upon the inclination of the ray to the optic axis. This is the EXTRAORDINARY RAY, and its refractive index varies between the value for the ordinary ray and another value which is either greater or smaller than the former, accordingly as substance is "positive" or "negative." If the substance be sufficiently thick, these portions emerge as two distinct rays which have undergone unequal refraction.

Double Riveting (*Eng.*) Two lines of rivets instead of one. The latter is more commonly used.

Doubles (*Eng., etc.*) Sheets of iron from about $\frac{1}{30}$ to $\frac{1}{50}$ in. thick, or 20 to 25 B.W.G. (*see* WIRE

GAUGES), prepared for coating with tin to make TIN PLATE (*q.v.*)

Double Samara (*Botany*). A type of fruit where the pericarp is winged and the fruit breaks into two or more winged portions (*e.g.* maple).

Double Sharp (*Music*). A sign (×) which raises a note a whole tone.

Double Shear Steel (*Met.*) *See* SHEAR STEEL.

Double Shrinkage (*Eng.*) *See* DOUBLE CONTRACTION.

Double Stars (*Astron.*) Stars which lie apparently so near to each other that only a magnifying power will separate them. There are two classes, physical doubles and optical doubles.

Doublet (*Cost.*) A close-fitting garment reaching from the neck to a little below the waist. It was worn in England, generally by men, from about the middle of the fourteenth century until the time of Charles II. It varied extensively in form, sometimes being without sleeves, and sometimes devoid of the short skirt.

—— (*Elect.*) Used in theory of electrical images to denote a system of two small equal charges of opposite sign separated by an exceedingly small distance. The "moment" of the doublet is the product of one of the charges multiplied into distance between them, and this product is always a finite quantity. The term is used in a similar sense in theory of magnetism.

—— (*Photo.*) A photographic lens consisting of two separate single lenses mounted in a tube. By the use of a suitable doublet distortion of the image can be corrected.

Double Tenons (*Carp. and Join.*) Two tenons side by side and parallel to each other. If doubled in width only, they are termed single tenons. *See* TENONS.

Double Threaded Screw (*Eng.*) A screw with two parallel threads (*i.e.* two separate helices) instead of one; used in certain cases where a comparatively fine thread of quick pitch is required.

Double Warp (*Lace Manufac.*) When the warp system of threads numbers twice that of the bobbin system. Two warp threads to one bobbin thread throughout the whole width of the web.

Double Webbed Girder (*Eng.*) A BOX GIRDER, *i.e.* one with the top and bottom booms united by two parallel webs.

Doubling (*Cotton Manufac.*) The twisting together of two or more threads so as to make one strong resultant thread known as FOLDED YARNS. Used for making strong fabrics, sewing cotton, crochet cotton, etc. Three forms of machines are used: (1) the ring doubler, (2) the twiner, (3) throstle or flyer. Cotton threads may be either (*a*) dry doubled, (*b*) wet doubled. The term is sometimes used when running two or more threads together on a bobbin without twisting.

Doubling Course (*Build.*) A double row of slates at the eaves of a roof. *See* ROOFS.

Douglas Fir. *See* WOODS.

Doulting Stone. *See* BUILDING STONES.

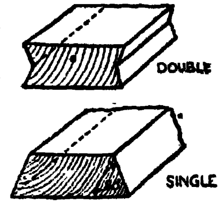
Doup, Doupe, or Dupes (*Textile Manufac.*) A type of heald used in gauze weaving. *See* HEDDLE.

Doup, Doupe, or Dupes (*Silk Manufac.*) An interlacing coupling or lash used in the manufacture of gauze, also for making a fast edge when two or more widths of work are made together in a loom.

Dove (*Art*). (1) In Christian art the dove is the symbol of the Holy Ghost. (2) A vessel in the form of a dove was formerly used for enclosing the Pyx in Eastern churches.

Dovetailing (*Join.*) Dovetails consist of splayed pins on one part and sockets on the other. The splay or slope should be 80°, *i.e.* 10° out of square. In common dovetailing the joints are visible in both boards. In dovetailing used in drawer fronts the joint can be seen on the side of the drawer, *i.e.* in one board only. In BLIND or SECRET DOVETAILING, used in some kinds of finished cabinet work, the joints are entirely concealed, so that the two boards appear to be MITRED (*q.v.*) together.

Dovetail Key (*Join.*) A form of wooden key with its edges sloping.



DOVETAIL KEYS.

Dovetail Saw. A light tenon saw used for cutting dovetails, and for small work generally.

Dowel (*Carp., Build., etc.*) (1) A wooden pin used in joining two boards edge to edge instead of a tongue and groove. (2) An iron pin fixed in a stone in such manner that a portion of it projects and fits into a hole made in another stone alongside. The joint thus made is called a DOWEL JOINT. (3) A short piece of slate, used in making a joint in masonry.

—— (*Pattern Making*). In pattern making the dowelled joints are intended to come apart easily for convenience in moulding. The dowels are usually brass or iron pins, fitting into metal sockets; they are provided with flanges, by which they are screwed to the pattern.

Dowel Plate. A steel plate with holes in it for making wooden dowels of various sizes: the wood is trimmed roughly to size and then driven forcibly through a hole in the plate. As the hole is made slightly conical, a cutting action is exerted which trims the wooden rod up to a cylindrical form.

Dowlas (*Linen Manufac.*) (1) A heavy plain texture linen used in the brown state for aprons and in white for interlinings of collars, shirt fronts, etc. (2) The name applies also to a strong calico made in imitation of the foregoing.

Downpipe (*Plumb.*) A rainwater pipe.

Downtake (*Met., etc.*) (1) A passage by which hot gases are led from the cone of a blast furnace to the base. (2) Any passage for the downward flow of gases, etc., as in some forms of boiler setting.

Downthrow (*Geol.*) The amount of dislocation which rocks have undergone where they have been let down by faults. The correlative to downthrow is UPCAST.

Dowson Gas (*Eng.*) A mixture of WATER GAS and PRODUCER GAS (*q.v.*), formed by blowing air and steam through redhot coke. Its uses are much the same as producer gas, but it has a greater calorific value.

Dutch Marble Paper (*Binding*). A marbling (for either paper or book edges) in which the colours are drawn together and intermingled by means of a wire comb. Thus in place of the ordinary "shells" or "veins," Dutch marble presents a series of small sharp scollops of varying colours.

Dracæna (*Botany*). A genus of *Liliaceæ* remarkable for their arborescent growth. The resinous exudation from the stem is one source of DRAGON'S BLOOD, and the leaf fibres are used in commerce.

Drachm *or* **Dram.** *See* WEIGHTS AND MEASURES.

Draff. Spent grain from a whisky mash.

Draft (*Eng., etc.*) A preliminary sketch. Less frequently the term is used for a drawing otherwise than preliminary.

—— (*Textile Manufac.*) *See* DRAFTING.

Drafted Margins (*Masonry*). A narrow margin chiselled round the edges of stone blocks, the centre portion of the stones being hammer dressed.

Drafting (*Textile Manufac.*) Arranging the order in which the threads are to be drawn through the healds. Usually imparted to the drawer-in by means of a chart or plan called a DRAFT or DRAFTING PLAN. *See* DRAWING IN.

—— (*Lace Manufac.*) The art of arranging and manipulating on paper the various threads that will eventually compose the pattern of lace in the lace machine. The correct attainment of all the necessary movements of the threads by mechanical means.

Drag (*Foundry*). The lower portion of a MOULDING BOX (*q.v.*)

—— (*Typog.*) A term applied to a printed sheet which shows slurring or doubling.

Drag Bar (*Eng.*) The bar by which a truck, locomotive, traction engine, etc., is attached to a following truck.

Drag Bolt (*Eng.*) The bolt sometimes used in fastening DRAG BARS (*q.v.*) together.

Drag Link (*Eng.*) The levers, etc., used to move the LINK MOTION (*q.v.*) of an engine.

Drag on Armature Conductors (*Elect. Eng.*) The mechanical force experienced by a conductor in which a current is flowing when moved so as to cut across magnetic lines of force. This drag is at right angles to the conductor and tangential to the armature, and tends to rip the windings off the surface of the core. If the conductors are wholly or partially embedded in iron, this drag is transferred, wholly or partially, from the conductors to the iron. This fact is of vital importance in electrical engineering.

Dragon Beam (*Join.*) A beam keyed to the angle tie at the corner of a building to receive the thrust of a HIP RAFTER (*q.v.*) *See also* ROOFS.

Dragon's Blood (*Paint., etc.*) A rich dark red pigment made from a brittle resin which encrusts the scaly fruit of an East Indian palm, *Calamus draco*, which yields also the RATTAN CANE of commerce. Formerly obtained from the stem of several species of *Dracæna* (*Liliaceæ*). Dragon's blood is soluble in alcohol, benzene, carbon disulphide, and caustic soda. On destructive distillation it yields, among other products, toluene and styrene (*q.v.*) It is much used as a pigment in various varnishes, French polish, etc.

Drag Plate (*Eng.*) The hinder part of the base plate of a locomotive, so called because the DRAG BAR (*q.v.*) is fastened to it.

Drag Spring (*Eng.*) A powerful spring attached to a DRAG BAR (*q.v.*) to diminish the sudden jerk when the engine starts.

Drag Surface (*Eng.*) The surface of the blade of a screw propeller which is next to the vessel.

Drainage (*Sanitation*). Strict attention to the drainage system of houses is highly important from the hygienic standpoint. In a modern system of drainage the following requirements, amongst others, should be complied with: (*a*) all drains to be watertight; (*b*) carefully laid on a bed of concrete with a suitable fall; (*c*) all inlets to the drains, except ventilating openings, to be properly trapped; (*d*) drains to be disconnected from the sewer by means of a trap, at which point a manhole should be built; (*e*) branch or tributary drains should join one another obliquely in the direction of the flow, and not by right-angled junctions; (*f*) all joints to be well made; (*g*) adequate provision made for ventilation. *See also under* SANITATION.

Drain Cock (*Eng.*) A small tap for running off water condensed in the cylinder of an engine. Also termed a PET COCK.

Drains and Water Closets (*Hygiene*). *See* SANITATION.

Dram *or* **Drachm.** *See* WEIGHTS AND MEASURES.

Drapery Panel (*Join.*) A panel carved to represent the folds of drapery. *See* LINEN FOLD.

Draught (*Eng.*) The air supply of a furnace or boiler fire. *See also* NATURAL DRAUGHT, FORCED DRAUGHT.

—— (*Pattern Making*). The tapering off of a pattern to facilitate its removal from the mould.

—— (*Textiles*). *See* DRAFTING.

Draught Bar (*Eng.*) A DRAG BAR (*q.v.*)

Draw (*Cotton Spinning*). Referring to the complete outward and inward run of a mule carriage, usually a stretch of 63 to 64 in. During the complete draw all the operations necessary in the spinning and winding of a thread are performed. The speed of the mule is usually indicated by the number of draws per minute.

—— (*Typog.*) A term applied to part of a line of type drawing out on to the roller during the inking of the forme, owing to imperfect justification.

Drawback (*Foundry*). A portion of a mould which can be removed from the rest to enable the pattern to be withdrawn, etc. A drawback is supported by an iron frame or plate of suitable shape, and is rigidly fixed in place when the casting is being made.

Draw Bar (*Eng.*) A DRAG BAR (*q.v.*)

Draw Bit (*Lace Manufac.*) The movable portion at the end of the dropper slides or boxes to which the guide bars are attached, enabling them to be correctly adjusted.

Draw Boring (*Carp. and Join.*) A method of fixing (and drawing up the shoulders of) tenons with wooden pins. The pin is driven into a hole bored through the tenon and the material on each side of the mortice.

Draw Boy (*Textile Manufac.*) A piece of mechanism for operating the frame containing the cords for lifting the harness and forming a shed in the warp. Formerly performed by a boy.

Draw Door Weirs (*Civil Eng.*) A WEIR or DAM (*q.v.*) in which the water is retained by doors or gates which can be raised vertically when there is too large an amount of water passing, as in floods. The HALF TIDE LOCK at Richmond furnishes an example.

Draw Filing (*Eng.*) Putting a finish on metal by moving a file backwards and forwards in a direction at right angles to its own length, so that the teeth only act very slightly.

Drawing (*Cotton Spinning*). A drawing out or attenuation of slivers prepared on the carder or comber with the object of reducing inequalities in thickness, and also further attempting to place individual fibres parallel by means of four lines of rollers revolving at different speeds.

—— **Architectural.** Drawing to scale with mathematical instruments, plans, elevations, perspective views of buildings, or portions of buildings.

Drawing Box (*Textile Manufac.*) One of a series of machines for straightening and attenuating the wool in making worsted yarn.

Drawing Down (*Eng.*) Altering or diminishing the cross section of a forging by hammering.

Drawing Fires (*Eng.*) The removal of a fire when the steam is no longer needed.

Drawing, Freehand. The practice of drawing in outline, from diagrams, forms either natural or conventional, without mechanical aid; the hand being under guidance of the eye only. It constitutes part of the elementary training of a draughtsman.

Drawing from Nature. Depicting by means of pen, pencil, or brush any natural object, animate or inanimate. The drawing may be either a complete work of art in itself, or may be simply a study, to be used as material for pictorial work or design.

Drawing from the Cast. Drawing from a *facsimile* of natural objects or objects of art which have been reproduced in plaster of Paris. The uniform whiteness of the cast (*q.v.*) renders it specially suitable for the study of light and shade.

Drawing from the Flat. Copying in "freehand" flat diagrams of objects, ornaments, or pictures.

Drawing In (*Textile Manufac.*) The ends or threads are drawn singly or otherwise through the eyes or mails of healds or harness in some prescribed order, so as to produce a definite pattern or design in the cloth. Also termed LOOMING.

Drawing, Machine. Plans, elevations, sections, etc., of machinery and engineering structures accurately drawn to scale. They are prepared in the "drawing office" for the guidance of pattern makers, boiler and engine smiths, fitters, turners, machinists, and the men employed in the erecting shop. They give full details and measurements of every part of the piece of work, and the construction and erection are carried out according to these details.

Drawing of Patterns (*Foundry*). The removal of patterns from the mould.

Drawing of Tubes (*Eng.*) *See* TUBES.

Drawing On *or* **Pulling On** (*Eng.*) The method by which large wheels are set on their shafts. Large bolts are fixed to a heavy metal cross (which is rigidly attached to the shaft), so that their nuts pass between the arms of the wheel, and press on the latter by means of plates. The tightening up of the nuts gradually forces the wheel on to the shaft.

Drawing Pen. A pen in which the ink is retained between two flat blades of steel bent towards each other at their points. The distance apart of the blades can be regulated, and the pen then produces lines of great uniformity.

Drawing Process (*Textile Manufac.*) *See* DRAWING.

Drawing Temper (*Eng.*) The partial removal of the hardness or temper (*q.v.*) of steel by heating it to redness and cooling slowly. It is really a form of annealing (*q.v.*)

Draw Knife. A knife with a handle at each end set at right angles to the blade. Used for trimming up wood, especially long pieces, of small width or diameter.

Draw Loom (*Textile Manufac.*) A type of harness loom used before the invention of the Jacquard, so called on account of the harness being drawn or lifted by a draw boy in forming the shed.

Draw Plate (*Eng.*) The perforated plate, usually of hardened steel, through which wire is "drawn." *See* WIRE DRAWING.

Draw Rollers (*Cotton Spinning, etc.*) Essential adjuncts to spinning machinery. Fitted on to draw frames, flyer frames, ring frames, mule, and comber. In England they are usually covered with specially prepared sheepskin leather. Three chief forms: (1) Solid leather covered. (2) Loose boss. (3) Metallic fluted roller.

Dredger (*Civil Eng.*) A machine for excavating the bottom of a channel, *i.e.* one which works under water, as opposed to an EXCAVATOR (*q.v.*), which works on dry land.

Drenching (*Leather Manufac.*) Light skins for moroccos or gloves after bating are "drenched" in a tepid solution of bran and water. The gluten of the bran ferments, forming organic acids. These acids open up and swell the skins, and dissolve out any remaining lime.

Dresden. The royal Saxon porcelain manufactory commonly known as "Dresden" was established at Meissen on the Elbe, about ten miles from Dresden, in the year 1710, Herr Böttger being director. It was fostered under the direct patronage of August II., Elector of Saxony. The manufacture was, and still is, exclusively confined to hard paste, and the productions have become celebrated throughout Europe for beauty, refinement, and a characteristic style. "Dresden china" is perhaps best known by the dainty models of "Watteau" figures which were so largely used for the ornamentation of clocks, tazzas, candelabra, etc. In addition to these, the productions of the manufactory include a great variety of models of birds and animals, and useful and ornamental china of practically every description. *See* BÖTTCHER.

Dresser (*Eng.*) A block fitting into an anvil, over which certain bent work is forged.

—— (*Plumb.*) A wooden tool, usually boxwood, for flattening out sheet lead.

Dressing (*Cotton Manufac.*) A process of warp preparation for the loom. There are several systems, two of which are given. YORKSHIRE DRESSING (for coloured work): In this system the yarn is ordered in the ball warp, and after being dyed and sized, all the threads are run side by side, according to pattern, on to the weaver's beam. SCOTCH DRESSING (for grey work): The yarns are run from back beams placed at both ends of machine, through a paste or size, on to the weaver's beam fixed in the centre. A more particular and expensive process than sizing, and adopted for best work only.

—— (*Lace Manufac.*) A process applied to machine made lace which can only be carried out while the lace is in the "web" or piece. It implies and comprises all the various processes of scouring, bleaching, mordanting, dyeing, staining, and dressing, this last process consisting of stretching the web of lace upon special machinery in a room supplied with heated air and every appliance for drying it quickly after being starched.

—— (*Linen Manufac.*) When linen yarn is being woven, especially if it has passed through any finishing process, it is liable to fray and break. To avoid this it has to be run through a mixture of flour or starch mixed with tallow, wax, gloy, etc., which is called dressing. It is mostly used cold, and differs from the sizing used in the cotton trade.

—— (*Mining*). The separation of the lighter and heavier portions of the crushed ore. *See* TRUE VANNER, *etc.*

—— (*Plumb.*) To dress lead is to flatten it with a DRESSER (*q.v.*)

Dressing a Forme (*Typog.*) Placing the furniture around the naked forme. Sometimes called "clothing a forme."

Dressing Off, Fettling, *or* **Trimming** (*Foundry*). Cleaning up castings, breaking off runners, and removing cores previous to sending the work from the foundry.

Dressings (*Build.*) The stonework fixed round window and door openings.

Driers (*Chem.*) An absorbent powder, generally gypsum or barytes, added to superphosphates to prevent pastiness.

—— (*Dec., etc.*) Materials added to paint to assist in "drying," *e.g.* hardening by the absorption of oxygen. Decorators use principally "patent driers," which are supplied in paste form, and consist of various mixtures, such as zinc sulphate, litharge, and lead acetate ground in boiled oil and mixed with Paris white, white lead, and manganese acetate. Most patent driers are largely adulterated with barytes, gypsum, etc. Liquid driers are used to a limited extent in England, but almost exclusively in the United States. One of the best known varieties is called "TEREBINE," and is made from gum copal, linseed oil, and litharge boiled together. To the use of an excess of driers may be attributed many of the defects which so often occur in house painting. Driers such as red lead, litharge, manganese oxide, borate, sulphate, and oxalate and zinc oxide, and sulphate, sugar of lead, etc., are largely used in the manufacture of boiled oils, varnishes, lacquers, printing inks, coach colours, etc. Driers are sometimes called SICCATIVES.

Drift (*Eng.*) A tool used to give a final form to drilled or punched holes, into which it is driven by a hammer; also used by boilermakers to form a clear hole for a rivet when the punched holes in the plates to be riveted do not exactly coincide.

Drift (*Mining*). A passage or level from one part of a mine to another for working, ventilation, or draining; especially a passage driven in the direction of a mineral vein.

Drift Currents (*Meteorol.*) Ocean currents produced by prevailing winds.

Drifting (*Eng.*) The using of a DRIFT (*q.v.*)

Drill (*Eng., etc.*) A tool for boring holes, held and rotated by some form of brace, drill stock, or machine. The term is often loosely applied to signify the drill stock or drilling machine itself. *See also* TWIST DRILL, *etc.*

—— (*Linen Manufac.*) A twilled texture, usually three, four, or five end; or may be a fancy twill. It is a strong make of cloth used for linings, vestings, trouserings, etc., and is commonly known as three leaf or DIAGONAL DRILL, four leaf or FARMERS' DRILL, and five leaf or MEDIUM or HEAVY DRILL. It is made brown, white, striped, checked, etc.

—— (*Mining*). The tool used for making holes in which explosives are placed for blasting. It is often "armed" with diamond fragments (*see* BORT) for cutting hard rock.

Drill Chuck (*Eng.*) A small CHUCK (*q.v.*) which holds a drill either in a lathe or drilling machine.

Drilled Plates (*Eng.*) The plates of boilers, built-up girders, etc., are often strained considerably by punching the rivet holes. Plates in which all the holes have been made by a drilling machine are free from this fault, and are often used.

Drill Feed (*Eng.*) The mechanism which moves the drill up to its work. It may be automatic or may be worked by the operator.

Drilling Cramp (*Eng.*) A frame or cramp which is used to press a drilling brace or ratchet brace up against a piece of work which cannot be placed on a drilling machine.

Drilling Machine (*Eng.*) A machine worked by hand or power, which drives a drill and at the same time feeds it up to its work. *See also* PILLAR DRILL, RADIAL DRILL, WALL DRILL, *etc.*

Drilling Table (*Eng.*) A cast iron plate, furnished with slots and holes, for holding work in position in a drilling machine.

Drill Plate (*Eng.*) A plate fixed to the loose headstock of a lathe in order to press a piece of work up against a drill fixed in a drill chuck.

Drill Spindle (*Eng.*) The main revolving part of a drilling machine; it carries the drill itself, and can be "fed" or caused to move in the direction of its own length, without ceasing to rotate, by means of the feeding mechanism.

Drip (*Chem. Eng.*) The ACID DRIP is a gauge on a vitriol chamber. It resembles a horn, the wide mouth of which looks upwards in the chamber, while the pointed end is connected to a swan-neck outside. It acts in the same way as a rain gauge, by catching the shower of acid as it forms in the chamber, and collecting it so that the yield and quality can be tested.

—— (*Plumb.*) A step (drip) formed in gutters and flats at the ends of the sheets of lead or zinc to do away with the necessity of soldering.

Dripstone (*Architect.*) *See* FLOOD MOULD.

Driver (*Silk Manufac.*) *See* PICKER.

Driving (*Mining*). A general term for cutting or making a level, adit, or other passage in a mine. The making of shafts is usually termed SINKING.

Driving Axle (*Eng.*) A shaft or axle which transmits rotation to a wheel which is keyed or otherwise fixed on to it.

Driving Blade (*Lace Manufac.*) That part of the Jacquard that contributes the power to move the guide bars.

Driving Chain (*Eng.*) A chain such as that of a cycle or motor car, which communicates motion from one toothed wheel to another. *See* CYCLES.

Driving Chuck (*Eng.*) A chuck with a projecting pin which engages a CARRIER (*q.v.*) fixed on a piece of work running in the lathe between the centres, and causes it to rotate.

Driving Fit (*Eng.*) A piece of work which fits very tightly into its place, so that it can only be driven home (*i.e.* into place) by considerable force applied with a hammer or mallet.

Driving Gear (*Eng.*) (1) The levers and handles by which an engine or machine is controlled. (2) The gearing through which the power is transmitted from one part of a machine to another, *e.g.* from the engine of a car to the driving axle.

Driving Horns (*Elect. Eng.*) Projections which overcome the drag (*q.v.*) on the armature conductors, and cause them to rotate with the shaft and core of the armature. In toothed core discs the teeth themselves serve this purpose.

Driving Side (*Eng.*) The tight side of a belt, *i.e.* the side which is in tension, and therefore transmits the power.

Driving Wheels (*Eng., etc.*) The wheels of a locomotive, car, etc., which are actuated by the engine, and which cause the motion of the vehicle.

Dromos (*Architect.*) An enclosed passage such as one leading to a tomb buried under a tumulus.

Drop (*Carp. and Join.*) *See* PENDANT.

—— (*Met.*) The completion of the decarburisation in the Bessemer process; it is marked by the sudden "dropping" of the flame from the converter.

Drop Black (*Paint., Dec., etc.*) A term applied to a variety of black pigments which are made in an irregular conical form. This is produced by mixing a little gum water with the black and allowing it to drop from the mill in which it is ground. An example is FRANKFORT BLACK, made from vine twigs, cork cuttings, etc.; but other blacks made from bones and animal refuse are often made in this form.

Drop Bottom Cupola (*Met., Foundry, etc.*) A CUPOLA (*q.v.*) in which the bottom can be removed, allowing the remains of the fire, slag, etc., to fall into a pit or space beneath.

Drop Box (*Textile Manufac.*) A type of power loom in which the shuttle boxes have a vertical up and down movement. Originally the boxes dropped simply by gravity.

Dropped Head (*Typog.*) Chapters or sections of a book which commence a new page are usually started about two-thirds the way down the page, and this constitutes a dropped head.

Dropper (*Lace Manufac.*) An instrument of precision used in the Jacquard for the purpose of giving accurate movement to the guide bars. Droppers are selected singly or in combination, and depend upon the principle of the wedge for their effectiveness.

—— (*Mining*). A subsidiary vein running downward from a lode.

Dropper Boxes (*Lace Manufac.*) The space between the slides in the Jacquard, wherein the droppers work. *See* DROPPER.

Dropper Gauge (*Lace Manufac.*) A measure to test the accuracy of droppers of every size or denomination used in any particular lace machine. *See* DROPPER.

Dross (*Met.*) Impurities which rise to the surface of metals when melted; also inferior material generally.

Drosser (*Glass Manufac.*). An iron frame while it is being annealed.

Drug. The Sale of Food and Drugs Act, 1875, defines the term "drug" as including "medicine for internal or external use." Difficulties frequently arise in administration when substances are used both medicinally and commercially. To settle the technicalities appeal is made to a magistrate.

Drum (*Cotton Manufac.*) The hollow cylinder in which steam is applied to printed fabrics in order to fix the colours.

—— (*Eng. etc.*) (1) A large pulley or cylinder round which a belt passes or a rope or chain is wound. (2) A cylindrical chamber used in flues, stoves, and heating apparatus. (3) A cylindrical or barrel-shaped metal vessel (usually of sheet iron, used instead of a wooden barrel for holding liquids or solids, such as oil, paint, white lead, etc.

—— (*Join.*) A cylindrical structure, used in building up various pieces of circular woodwork; a large drum is also used for supporting a number of bars of wood, of square section, which are arranged round its periphery and turned in a lathe in order to form balusters (*q.v.*)

—— (*Lace Manufac.*) A cylinder of wood or tin, about 18 in. in diameter, upon which are wound threads, varying in number from 60 to 120. This forms a supply for winding the brass bobbins. The utility consists in the equal amount of tension obtained.

—— (*Music*). *See* BASS DRUM, KETTLE DRUM, SIDE DRUM, *under* MUSICAL INSTRUMENTS.

Drumming (*Leather Manufac.*) A process frequently employed is to place leather in large rotating drums containing tan liquor, grease, dye, or weighting materials, as required. This treatment is known as "drumming."

Drum Washer (*Paper Manufac.*) A hollow cylindrical vessel, covered with wire gauze, used for removing dirty water from pulp.

Drum Weir (*Civil Eng.*) A WEIR or DAM (*q.v.*) with a gate hinged so as to rotate about a horizontal line. The hinge lies in the plane of the river bed, the lower half of the gate moving in a hollow or drum of quadrant shaped section situated below the level of the river bed. The height of the water in the channel above the weir can be controlled in a very perfect manner by turning the gate or sluice through an angle, so as to raise or lower the "sill" or top edge, thus lessening or increasing the volume of water passing over.

Drum Winding (*Cotton Manufac., etc.*) A system of winding yarn on to bobbins, or in the form of cheeses, by means of frictional contact with drums. Two methods are employed, STRAIGHT and QUICK TRAVERSE. *See also* WINDING.

—— (*Elect Eng.*) *See* ARMATURES.

Drunken Saw (*Carp., Eng., etc.*) A circular saw whose plane is not at right angles to the axle; it is used for cutting a groove in timber, the width of the groove depending on the angle at which the saw is set. Now usually superseded by a thick saw, set square on the axle, which cuts an accurate groove of its own thickness.

Drupe (*Botany*). The "stone fruit" as seen in the plum, cherry, peach, etc. The pericarp, or fruit wall, is in three layers: the rind (EPICARP), the pulp (MESOCARP), and the stone (ENDOCARP). The kernel of the stone is the seed.

Drusy Cavities (*Geol.*) Small cavities occurring in eruptive or other rocks, commonly lined with crystalline minerals.

Dry Area (*Build.*) An enclosed space round an external wall, the bottom of which is below the ground level.

Dry Brush (*Moulding*). A brush used to remove sand or dust, as distinguished from one used to damp the surface of the mould.

Dry Bulb Thermometer (*Meteor.*) *See* HYGROMETERS.

Dry Cells. *See* CELLS, PRIMARY.

Dry Copper (*Met.*) *See* COPPER.

Dry Dock (*Civil Eng.*) *See* DOCKS.

Drying Cylinder (*Paper Manufac.*) A hollow iron cylinder heated internally by steam, used for drying paper.

Drying of Paint (*Dec.*) Oil paint dries or becomes hard partly by absorbing oxygen from the air, which combines with the linseed oil, and partly by the evaporation of the volatile spirit turpentine (*q.v.*) To assist in the oxidation, driers (*q.v.*) are sometimes added, but this is unnecessary in the case of some pigments, such as red lead. With the object of facilitating the drying of newly applied paint, fires or gas jets are sometimes lighted. This is, however, worse than useless, as the heat does not assist the drying, but retards it, owing to the oxygen that is used up. When paint or varnish does not dry, but remains sticky, it is a sign that it has been applied to a dirty and greasy surface. *See also* DRIERS.

Drying Oils (*Paint., Dec., etc.*) Those oils which dry or become hard on exposure to the air. LINSEED OIL (*q.v.*) is by far the most important of these, but POPPY SEED OIL, HEMP SEED OIL, WALNUT OIL (*q.v.*), etc., are also used by painters to some extent. The oils of this class are also called FIXED OILS, because they are not changed by distillation.

Drying Room (*Typog.*) A room heated by hot water or steam to a uniform temperature of about 120° F., and employed to facilitate the drying of the printed work.

Drying Stove (*Moulding*). A furnace or oven used for drying CORES (*q.v.*) before placing them in the mould.

Dry Moulding (*Foundry*). Moulding in pure sand instead of in LOAM (*q.v.*)

Dry Pipe (*Eng.*) A perforated pipe placed horizontally inside the head of a steam boiler for drawing off steam from the whole length of the steam space. Sometimes a trough or half-pipe suspended by lugs about half an inch from the top of the boiler shell.

Dry Plate (*Photo.*) A plate carrying a gelatine film impregnated with salts of silver sensitive to light (*i.e.* the bromide, iodide, and chloride). The plate is usually glass, but may be transparent celluloid, which is light, flexible, and unbreakable; occasionally, however, paper is coated with the sensitive film. *See* PAPER NEGATIVES.

Dry Point. *See* ENGRAVING AND ETCHING.

Dry Spinning (*Linen Manufac.*) Flax may be spun wet or dry, the latter giving a softer and more spongy yarn, which suits better for making some cloths. When spun wet, the rove passes through hot water, which softens the gum in the flax and enables it to be drawn out into a finer and firmer thread.

Dry Steam (*Eng.*) Steam unmixed with fine particles of water, but not superheated (*q.v.*); it is really SATURATED WATER VAPOUR (*q.v.*), and begins to condense at once on cooling. *See also* PRIMING.

Dry Uptake (*Eng.*) The lower part of the flue of a marine boiler which is not surrounded by water; *i.e.* the flue is outside the boiler.

Dry Wood. Seasoned wood, free from sap. *See* SEASONING.

"D" Section Tubes (*Cycles*). These are useful for the horizontal bars forming the back forks, extending from the bottom bracket to the back axle, as they help to reduce the width of tread; but they are not in much favour in the latest machines, being inferior in strength to ordinary round seamless tubes.

"D" Trap (*Hygiene*). This trap, so called owing to its likeness to the letter D, is frequently met with in connection with the old "pan container" closet. It is a very bad type of trap, having too many angles and projections, and is not self cleansing.

Dubbing Out (*Plastering*). Forming a moulding in plaster roughly, preliminary to finishing off the work neatly.

Duck (*Linen Manufac.*) (1) A heavy make of plain texture linen cloth which has either a ribbed or a matt appearance according to make. It is also often made in fancy textures for vestings, trouserings, etc. (2) A Cotton fabric having the same appearance is also manufactured.

—— (*Her.*) In heraldry a duck is always called a CANNET, and appears without feet or beak.

——, **Eider** (*Zoology*). *Somateria mollissima* (family, *Anatidæ*; order, *Anseres*). The well known eiderdown is obtained from the nests, where it forms a covering to the eggs. The female bird plucks the down from her body, gradually increasing the amount during the period of incubation.

Ductility. The property of certain metals which allows them to be drawn out into wire; *e.g.* silver, copper, brass.

Ductless Glands (*Zoology*). The term applied to the thyroid, adrenal (suprarenal), pineal, and pituitary glands. The spleen and thymus glands are also included under this term.

Ductor (*Print.*) A duct, trough, or reservoir which holds the ink in a printing machine.

Duet, Duo (*Music*). A composition for two voices or instruments.

Dulcimer. *See* MUSICAL INSTRUMENTS—STRING (BY PERCUSSION).

Dulcite *or* **Dulcitol** (*Chem.*), $CH_2OH \cdot (CHOH)_4 CH_2OH$. Lustrous prisms; melts at 188°; sparingly soluble in water; sweetish taste. It is isomeric with mannitol, and with hydriodic acid gives the same hexyl iodide that mannitol does. With nitric acid it yields mucic acid. It occurs in Madagascar manna, and can be obtained from this and also by reducing lactose or galactose with sodium amalgam. It is a hexahydric alcohol.

Dull. (1) Blunt (in reference to a cutting tool). (2) In the case of metal, at a heat less than that at which the metal is usually forged or cast.

Dulong and Petit's Law (*Chem.*) The product of the atomic weight of an element and its specific heat is constant, *viz.* 6·4. The law only applies to the elements in the solid state. A few elements of low atomic weight and high melting points, such as beryllium, boron, carbon, and silicon, give a value less than 6·4; but in these cases it is found that the specific heat increases with the temperature, so that when the specific heat of these elements is taken at a high temperature the product, atomic weight and specific heat, approaches the normal. The constant 6·4 is often called the atomic heat. This law does not give accurate values for the atomic weights, but it is very useful in enabling a chemist to decide what multiple of the equivalent (*q.v.*) of an element must be taken to obtain the atomic weight, because equivalents can be determined with great accuracy.

Dumas' Measurement of Vapour Density. A method of finding the density of gases and vapours by weighing a flask of known volume which is full of the gas, and making a suitable correction for the loss of weight of the flask and its contents due to the fact that it is weighed in air, *i.e.* adding on the weight of the volume of air displaced by the flask. The gas or vapour must first be condensed, and a small amount of the liquid placed in the flask. The flask is then immersed in a bath at a temperature above the boiling point of the liquid until vapour ceases to issue from the neck. The flask is then sealed up, and the temperature of the bath at the instant of sealing is noted. The weight of vapour which will occupy the volume of the flask at a known temperature is thus found.

Dumfries Sandstones. *See* BUILDING STONES.

Dummy (*Plumb.*) A thick cane with a lump of lead on the end: used for beating out dents in lead pipes.

—— (*Print*). A set of sheets made up to resemble a book, magazine, etc. The object is to convey an idea of the size of a prospective publication, and if details are furnished, of the scope of such publication.

Dundee Sandstone. *See* BUILDING STONES.

Dunes (*Geol.*) A term almost entirely restricted to the hills of sand which occur in maritime regions. Large quantities of sand are stirred up by the waves during storms, and when these waves are driven on to the coast the water flows back to the sea, and sand is left on the shore. Sand reeds and various grasses bind the accumulation together, and thus help it to increase in size. Sanddunes are often important reservoirs of potable water.

Dunite (*Geol.*) A plutonic rock of granitic structure and ultrabasic composition. It consists essentially of olivine, with some pyroxene and iron ore, but with little or no felspar.

Dunlop Tyres (*Cycle*). *See* TYRES.

Dunted (*Pot.*) Dunted ware is practically the same as FLED WARE, the term being a colloquialism common to the Staffordshire potteries.

Duodecimals. The arithmetical processes involved in the multiplication together of feet and inches in finding areas and volumes in the English system of measures.

Duodecimo (*Print.*) A sheet of paper folded into twelve leaves, commonly called twelvemo and written 12 mo.

Duodenum (*Zoology*). The first loop of the intestine after leaving the stomach. It receives the bile and pancreatic juices.

Dupes (*Textile Manufac.*) *See* DOUP.

Duplex (*Watches and Clocks*). A frictional-rest dead-beat escapement, the escape wheel having two sets of teeth: one vertical set for communicating impulse; the other, horizontal, for producing the rests.

Duplex Lathe (*Eng.*) A lathe with two cutting tools acting simultaneously on opposite sides of the work; the tool at the back of the work is inverted. It is of great use in turning long shafts, as it is not only quicker than the ordinary method, but more free from errors due to the springing of the work and chattering.

Duplex Papers (*Paper Manufac.*) Papers coated with a different coloured mixture on either side.

Duplex Telegraphy. *See* TELEGRAPHY.

Duramen (*Botany*). The heart wood or central portion of the stem of a tree. It has lost the power of transference of water, and is harder and darker than the sap wood.

Duresco (*Dec.*) A washable water paint or distemper, having many of the characteristics of zinc white oil paint (*q.v.*) It is made without lime, gypsum, or natural barytes.

Duster (*Dec.*) A brush used by painters for removing dust before applying paint. In London and the southern part of England a round brush is usually employed, but in the north a flat brush is more generally employed. The latter possesses the advantage of being handy to get into corners and the spaces between the balusters on a staircase.

Dust Proof Bearings (*Cycles and Motors, etc.*) A bearing fitted with some form of cover or cap to prevent as far as possible the entry of dust.

Dust Sheets (*Dec.*) Cloths of unbleached sheeting used by painters over furniture, floors, etc., to protect them during repainting.

Dutch Bond (*Build.*) A similar bond to English, excepting that a threequarter brick is used in the STRETCHING COURSES (*q.v.*), and the closer omitted in the heading courses at the quoins. *See* BOND *and* ENGLISH BOND.

Dutch Bricks. *See* BRICKS.

Dutch Clinker (*Build.*) *See* CLINKER.

Dutch Liquid (*Chem.*) Ethylene dichloride. *See* ETHYLENE.

Dutch Metal *or* **Dutch Gold Leaf.** An alloy of 11 parts of copper and 2 parts of zinc. It is one of the most malleable alloys.

Dutch Pink (*Dec.*) A transparent yellow lake pigment, formerly much used by scenic artists and wallpaper manufacturers. When ground in oil it is useful as a glazing colour (*q.v.*)

Dutch School of Painting. *See* PAINTING, SCHOOLS OF.

Duty (*Eng.*) An old system of measuring the efficiency of an engine. It is the number of foot pounds of work performed by the combustion of one bushel of coal. The modern method is to observe the number of pounds of coal per INDICATED HORSE POWER HOUR (*q.v.*)

D Valve (*Eng.*) The common slide valve which has a cross section very much in the form of the letter D.

Dwell (*Print.*) The pause during which a sheet in course of printing is impressed on the type or forme. In the best platen machines this stationary period or dwell is somewhat lengthy.

Dwellings, Sites for and Structural Arrangements of. *See under* SANITATION.

Dyad Elements (*Chem.*) Divalent elements. *See* VALENCY.

Dyas (*Geol.*) A name often used instead of "Permian" for the lower sub-division of the New Red Rocks. In Britain it is most typically developed in the Eden Valley, where it consists of the Magnesian Limestone (and its Plant Beds), which overlies the Penrith Sandstone and its associated breccias. It was formerly known as the Lower New Red, and is again being recognised by that term. Dyas is correlative to Trias, or Upper New Red.

Dyes and Dyeing. Until the middle of the nineteenth century the substances used for producing colours on textile fabrics were mostly derived from the vegetable kingdom, and consisted of the wood, leaves, seeds, etc., of various plants. The discovery by Dr. Perkin, in 1856, of mauve, the first dye derived from coal tar, and the subsequent introduction of innumerable coal-tar dyes due to this discovery, have entirely revolutionised the art of dyeing. The earlier coal-tar dyestuffs usually known as ANILINE DYES yielded mostly bright colours of inferior fastness to light. In 1868, however, followed the synthesis of alizarine, a substance identical with the colouring matter of the madder plant, and yielding extremely fast colours, including Turkey red, on cotton. More recent discoveries have furnished us with the AZO DYES (which have largely displaced cochineal in wool dyeing); a series of colours, commencing with Congo red, which dye cotton direct in one operation, the sulphur dyes yielding fast colours on cotton; and synthetic indigo, identical with INDIGOTIN, the colouring matter of natural indigo. The only vegetable dyestuffs still used to any considerable extent are logwood, and to a gradually lessening degree natural indigo. The coal-tar dyestuffs now at the dyer's command enable him to produce every imaginable colour with almost any desired degree of fastness on every variety of textile material. *Methods of Dyeing:* These may be best explained by attempting a classification of the various dyes based on their application to animal and vegetable fibres. The methods of silk dyeing resemble those for wool, whilst linen and other vegetable fibres are dyed similarly to cotton. Dyestuffs may be divided into those which require a mordant and those which do not. A MORDANT is a substance which, when applied to the fibre in conjunction with a dyestuff, combines with the latter to produce a useful colour. The mordant is usually applied before the dye, as in dyeing a logwood black on wool. The wool is first boiled in a solution of bichromate of potash, and afterwards in a decoction of logwood. In special cases the mordant is applied after the dye; this constitutes the so-called STUFFING AND SADDENING method; or the mordant may even be applied together with the dye, as when a cochineal scarlet is dyed by boiling wool in a single bath with cochineal, a solution containing tin, and oxalic acid. The group of MORDANT DYESTUFFS includes: (1) All the best known natural dyes (with the exception of indigo, turmeric, orchil, and catechu), such as logwood, the red woods (camwood, barwood, sanderswood, brazilwood, peachwood), madder, cochineal, the yellow woods (weld, old fustic, quercitron bark, flavine, young fustic), and Persian berries. (2) ALIZARINE and allied colours, most of which are derived from the coal-tar product anthracene; examples are alizarine, anthrapurpurin, flavopurpurin, alizarine orange, alizarine blue, anthracene blue, alizarine cyanine, anthracene brown, alizarine black, galleïne, coeruleïne, gallocyanine, etc. All these mordant dyestuffs have in themselves no colouring power, but when used in conjunction with a mordant they produce colours which vary according to the mordant employed. The most usual mordants are salts containing one of the metals chromium, aluminium, tin, copper, or iron. If five pieces of woollen cloth are boiled respectively in solutions of potassium bichromate, aluminium sulphate, stannous chloride, copper sulphate, and ferrous sulphate, and then dyed with alizarine, they will be coloured respectively bluish red, bright red, orange, dull violet, and deep violet. As a rule aluminium and tin mordants give the brightest colours, copper and iron the deepest, while chromium occupies an intermediate place. By far the most largely used mordants for wool are the bichromates of potash and soda; by boiling wool for an hour in a solution of one of these salts alone, or with small additions of acids or acid salts, it acquires the property of subsequently fixing any of the mordant dyes. The mordanting of silk and cotton is more difficult, especially the latter, which usually involves several operations; as a rule the solutions are applied cold or lukewarm. In one method of dyeing Turkey red on cotton, for example, the material is steeped successively in baths containing sulphated castor oil ("Turkey red oil"), basic sulphate of alumina, and chalk, the first two operations being usually repeated several times. Then follow dyeing with alizarine, a further treatment with oil, steaming, and soaping. Tannin is used as a mordant for cotton when dyeing with the basic colours. In this case the cotton is steeped for several hours in a solution of tannic acid or in a decoction of myrabolams, sumach, divi-divi, or other tannin matter, which is then fixed on the fibre by passing through a solution of an antimony or tin salt. The NON-MORDANT DYESTUFFS may be subdivided into ACID, BASIC, and DIRECT COTTON COLOURS. The BASIC DYES are applied to wool and silk by merely immersing the material in the hot colour solution; they are now seldom used for wool. Cotton is mordanted with tannin, and then dyed at a temperature below the boiling point. Except for the brightest colours, they have been largely replaced

by the direct dyes. Examples of this group are magenta, safranine, Bismarck brown, chrysoidine, auramine, malachite green, Victoria blue, methylene blue, methyl violet. The ACID DYES are dyed on wool and silk, with the addition of sulphuric or acetic acid to the dye bath; for cotton dyeing they cannot be used. For woollen piece goods they find a wide application, and are preferred in all cases where only a moderate degree of fastness is demanded and a rapid and simple method of dyeing is the chief consideration. Several hundred dyes of this class are known, including the azo scarlets (grocein, wool scarlet, etc.), naphthol yellow, picric acid, acid magenta, acid violet, fast red, cloth red, naphthol black, alkali blue, soluble blue, etc. A subdivision of this group comprises the EOSINE COLOURS, which yield bright pinks fast to washing, but very fugitive to light. They are dyed on wool with the addition of acetic acid, and occasionally on cotton in a concentrated bath containing common salt. The chief dyes of this class are eosine, erythrosine, phloxine, rose bengale, and rhodamine. The last named is somewhat faster than the rest, and may also be applied to cotton on tannin mordant. The ACID MORDANT DYES for wool are applied by first boiling the wool in an acid bath with the colour, and then adding the mordant to the same bath, and continuing to boil for some time longer. Such are the acid alizarine, anthracene acid, palatine chrome dyes, diamond blacks, etc. The DIRECT COTTON COLOURS or SUBSTANTIVE DYES, also known as the BENZIDINE COLOURS, are dyed on vegetable fibres in a boiling bath, to which is added salt or sodium sulphate, sometimes also carbonate of soda. In certain special cases the colours may be rendered faster to light or washing by an after-treatment with a metallic salt, *e.g.* copper sulphate. Certain direct dyes, *e.g.* primuline, may be converted after dyeing into other colours, possessing greater fastness than the original, by treating the dyed cotton with nitrous acid ("diazotising"), and then passing into a solution of certain phenols or amines, *e.g.* betanaphthol. The direct colours also number many hundreds. Bensopurpurine and chrysophenine are typical dyes of this class. Others bear names with the prefixes diamine-, Congo-, benzo-, direct-, cotton-, oxamine-, pyramine-, Columbia-, Titan-, etc. The SULPHUR or SULPHIDE DYES resemble the direct colours, but require the addition of sodium sulphide to the dye bath, and mostly yield colours fast to light, washing, and acids. They are distinguished by various prefixes: immedial-, katigen-, kryogen-, pyrogen-, vidal-, thionol-, cross dye-, sulphur-, etc. The older dyestuff, cachou de Laval, also belongs to this group. Of the non-mordant natural dyestuffs ORCHIL is dyed on wool with or without an acid, TURMERIC dyes all fibres without addition, and CATECHU is dyed without addition, and the colour developed by a boiling solution of bichromate or copper sulphate. Indigo extract, prepared by dissolving indigo in sulphuric acid, is an acid dye. Outside the groups enumerated remain a number of dyes which cannot be classified; of these the chief is INDIGO, including both the natural product, prepared from the indigo plant by a process of fermentation, and synthetic indigo, derived from coal tar. Indigo is applied to both animal and vegetable fibres in so-called indigo vats, in which the insoluble blue colouring matter is reduced to a colourless body, indigo white, and in this condition brought into solution by the addition of an alkali. The reduction may be brought about by purely chemical means or by fermentation. In the former case we have the bisulphite or hydrosulphite vat used for both wool and cotton, containing indigo, bisulphite of soda, zinc, and lime or caustic soda, and for cotton the zinc lime and copperas vats. Fermentation vats are in this country only used for wool, the woad vat, which contains indigo, woad, bran, madder, and lime, being the most important. For wool dyeing the temperature of the indigo vat is about 120° F.; cotton is dyed cold. After making up the vats the sediment is allowed to settle, and the material is then dyed in the clear greenish-yellow liquor. The goods as they come from the vat are green in colour; by the oxidising action of the air indigotin is regenerated, and they are dyed blue. The colour possesses great fastness to washing, acids, alkalis, etc., and in medium and dark shades is very fast to light. Indanthrene and flavanthrene, two colours of recent introduction, are dyed by a process resembling the bisulphite vat for indigo, and yield respectively blue and yellow colours of exceptional fastness. ANILINE BLACK is the fastest black known for vegetable fibres; it is an insoluble black pigment produced by the oxidation of aniline on the fibre. This may be brought about by working the cotton, etc., in a bath containing aniline, a mineral acid, and an oxidising agent. The presence of small quantities of salts of certain metals, *e.g.* vanadium, has a very favourable influence on the development of the black. Sometimes dyeing takes place in a cold solution, and the black is afterwards developed by steaming or ageing. If not well dyed, aniline black tends to rub off and to become green on exposure to acid vapours. PARANITRANILINE RED: Certain azo dyes may be produced on the cotton fibre by successively steeping in solutions of the different constituents of the colour. The best known dye of this class is paranitraniline red, produced by impregnating the cotton with betanaphthol, drying, and developing in a solution of diazotised paranitraniline. MINERAL DYES: These are now seldom used in dyeing, though still to some extent by the calico printer. They are Prussian blue, produced on cotton by successive treatment with prussiate of potash and iron salts, and on wool by decomposition of prussiates with mineral acids,—chrome yellow and orange (lead chromate); manganese brown (manganese hydroxide); and iron buff (ferric hydroxide). The MACHINERY employed in dyeing varies from a simple pot or tub, in which the material is stirred with a pole in the mordant or dye solution, to machines of greater or less complexity, in some of which, *e.g.* the OBERMAIER MACHINE, for loose wool, the material remains fixed in one position throughout the various operations, and the liquids are circulated through it. The choice of vessel depends on the nature of the material and at what stage of manufacture it is to be dyed. Wool may be dyed as loose wool, yarn, or pieces, also as slubbing, an intermediate form between loose wool and yarn; cotton as loose cotton, cops, yarn (warp or hank), or pieces; silk chiefly as yarn, occasionally in the piece. In selecting the dyes to be applied, not only the nature of the material must be considered, but also the purpose for which the finished goods are intended; and, taking this into account, dyes will be chosen according to their fastness to light, washing, and the finishing operations which the goods may undergo, *e.g.* milling, steaming, hot pressing, etc. For loose

wool very fast dyes are usually selected, since during the operations of manufacture into cloth the colour will be subjected to the destructive influences of light, scouring, and so on. An indispensable condition for satisfactory dyeing is that the material shall be previously thoroughly cleansed from natural or added grease and other impurities. The dyeing of UNION FABRICS, *i.e.* those containing fibres of different kinds, such as wool and cotton, wool and silk, etc., offers considerable difficulty; but by suitably combining the methods applicable to the simple fibres, it is possible to produce on a fabric containing the textile fibres in any combination either plain colours or effects dependent on each fibre being dyed a different colour. The correct combination of processes to achieve these results calls forth all the resources of the dyer's art. R.B.

Dyke (*Civil Eng.*) A barrier of masonry, earth, timber, etc., used to keep back floods, high tides, etc.

—— (*Geol.*) A term which originally meant a dividing line between two contiguous parts of a territory; hence applied to faults which dislocate parts of a coalfield, *e.g.* the Ninety Fathom Dyke in Northumberland. In geological descriptions the term is restricted to the more or less vertical sheets of intrusive rock which have consolidated from a fluid state, and now form wall-like masses in the country rock. Such dykes are generally replacive in their mode of occurrence; they may consist of eruptive rocks of any composition.

Dynamical Equivalent of Heat. It is found by experiment that one caloric, if entirely converted into work, would yield very nearly 42,000,000 ergs. Expressing the same result in engineers' units, we find that the heat necessary to raise 1 lb. of water through 1° F., if entirely converted into heat, is equivalent to 778 foot pounds.

Dynamic Metamorphism (*Geol.*) The mechanical (or mechanico-chemical) effect produced upon rock masses of any kind by movements of the Earth's crust acting under considerable vertical pressure. Usually the movements which give rise to this effect have taken place within the core of great masses whose upper surfaces have been bulged into uplands out of which mountains have afterwards been carved. Dynamic metamorphism usually takes the form of shearing, due to the differential movement of one part of the rock affected with regard to another part. All true SCHISTS (*q.v.*) are rocks which have been affected by these shearing movements.

Dynamics. The theory of forces which are not in equilibrium, as distinguished from STATICS (*q.v.*)

Dynamite. A mixture of an infusorial earth called Kieselguhr (*q.v.*) with nitroglycerine. The mixture is made by hand, and it contains about 75 per cent. nitroglycerine. The Kieselguhr is nearly pure silica (98 per cent. SiO_2). Varieties of dynamite are known as COLONIA, HERCULES, and VULCAN, all of which contain mealed gunpowder in addition to nitroglycerine. GIANT POWDER contains sodium nitrate, resin, and sulphur, as well as nitroglycerine and Kieselguhr.

Dynamo. A dynamo is a machine for converting mechanical into electrical energy. The types of machine by which this conversion has been accomplished are very diverse; but of recent years the evolution has been toward a few distinct types, the differences between which are chiefly dependent upon the various forms in which the electrical energy is required. These forms may for practicable purposes be classified as follows: I. Continuous current; II. Single phase alternating current; III. Polyphase alternating current. I. THE CONTINUOUS

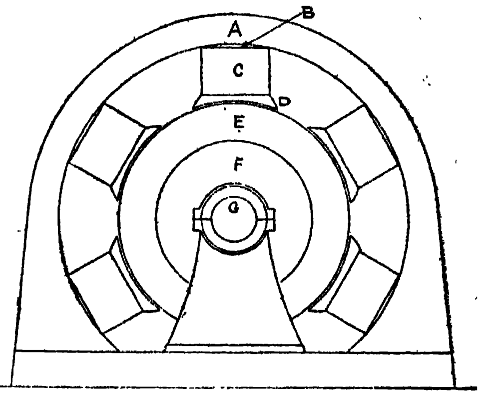


FIG. 1.—CONTINUOUS CURRENT DYNAMO (6 POLE). ELEVATION. FIRST VIEW.

CURRENT DYNAMO: A type of continuous current dynamo is shown in fig. 1. A stationary ring A of cast iron or steel carries a number of salient poles of wrought iron or steel B, each of which is provided with a field coil C of insulated copper wire. Each of the salient poles B terminates in a pole shoe D, and within the cylindrical space limited by the internal faces of the pole shoes an armature E and commutator F are revolved by means of mechanical energy applied to the shaft G, on which E and F are mounted. The armature E consists of a suitable

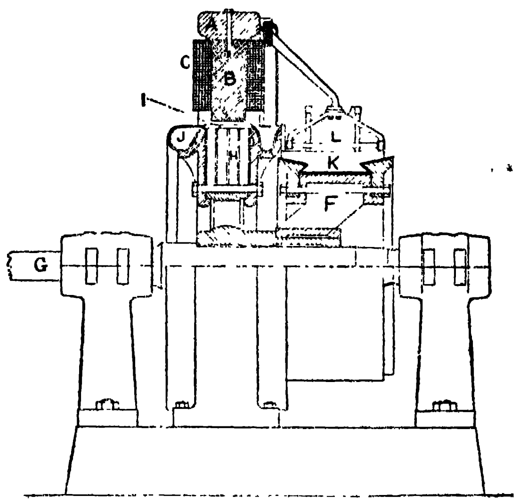

FIG. 1.—SECTION THROUGH POLE, ARMATURE, AND COMMUTATOR. SECOND VIEW.

spider carrying a core H of laminated iron or steel, which completes the magnetic circuit for the magnetic flux flowing through A and B in virtue of the magnetomotive force imparted to the field coils C by a continuous current sent through them, either from an independent external source, in which case the dynamo is said to be "separately excited," or from the dynamo itself, in which case it is "self excited." The external periphery of the laminations of which the

armature core is constructed, is provided with slots at I, carrying the armature winding, of which the end connections are seen at J. From suitable points in the armature winding, connections are carried to the commutator segments K. These commutator segments, of which a commutator generally contains a very large number, are flat plates of copper, generally of some such shape as that shown in the figure. These alternate with sheets of mica, which insulate them one from another, and they are further insulated from the commutator spider by suitably shaped cones and cylinders of mica or micanite. Brushes of carbon or copper, carried in suitable brush holders L, are arranged to bear upon the cylindrical surface of the commutator, and from the brush holders suitable circuit connections are made for transmitting the current from the dynamo to the point or points where it is required for lighting, power, or other purposes. In virtue of the revolution of the armature in the magnetic field, electromotive forces are induced in the armature conductors, and the amount of current delivered from the machine is proportional to the value of the resultant of these electromotive forces (*i.e.* to the terminal electromotive force) and to the resistance of the external circuit. The most convenient formula for determining the voltage of continuous current dynamos is $V = 4{\cdot}00\ T\ N\ M\ 10^{-8}$, in which V = the voltage generated in the armature; T = the number of turns in series between the brushes; N = the number of magnetic cycles per second; M = the magnetic flux (number of C G S lines) included or excluded by each of the T turns in a magnetic cycle. V, the voltage, is approximately constant during any period considered, and is the integral of all the voltages successively set up in the different armature coils according to their position in the magnetic field. It will be found that the relative magnitudes of T, N, and M may (for a given voltage) vary within wide limits, their individual magnitudes being controlled by considerations of heating, electromagnetic reactions, and specific cost and weight. The production of the flux M is effected in several ways, the chief of which are as follows:—(1) *Permanent Field Magnets:* The field magnets are built up of plates or layers of hard steel, permanently magnetised in the same way as an ordinary horseshoe magnet. This type is usually termed a MAGNETOELECTRIC MACHINE, and has only been used for medical purposes or as a mere toy until very recently; but it is found to be very convenient for the production of an electric spark for the ignition of the charge in gas and petrol engines, and is now becoming increasingly common. In by far the larger number of dynamos the field is produced by electromagnets, as in the type described above, and these differ among themselves in the manner in which the current is obtained. (2) *Separately Excited Dynamos:* The coils of the field magnets are supplied with current from an independent source. In large electric lighting stations a subsidiary dynamo is often used solely for this purpose, and is termed the EXCITER or EXCITING DYNAMO. (3) *Series Machines* (fig. 2):

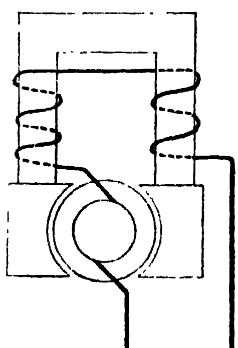

FIG. 2.—SERIES WOUND DYNAMO.

In this form the whole current produced by the machine passes round the coils of the field magnets, which consist of relatively few turns of wire of large cross section. The coils of the field magnets thus form part of the main circuit. (4) *Shunt* or *Shunt Wound Machines* (fig. 3): In these the coils of the field magnets consist of a large number of turns of somewhat fine wire, connected to the terminals of the machine in such a way that a portion of the main current passes round them, *i.e.* the coils form a SHUNT to the main circuit. This is the most usual method of excitation in machines intended for ordinary electric lighting. The method of making the connections for series and shunt machines is shown diagrammatically in figs. 2 and 3.

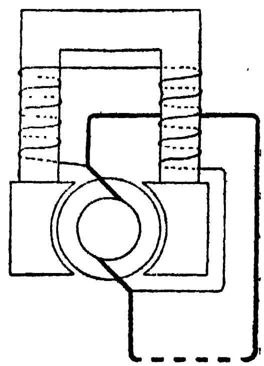

FIG. 3.—SHUNT WOUND DYNAMO.

In fig. 2 the whole current must pass through the field coil, which is in SERIES with the main circuit, while in fig. 3 the field coil forms a SHUNT or alternative path for the current. (5) *Compound Winding* (fig. 4): In this case there are both series and shunt coils. The main current flows through the series coil, but a portion is shunted off through the shunt coil; a decrease in the resistance of the main circuit will then increase the amount of current flowing through the series winding, and therefore increase the magnetisation of the field magnets.

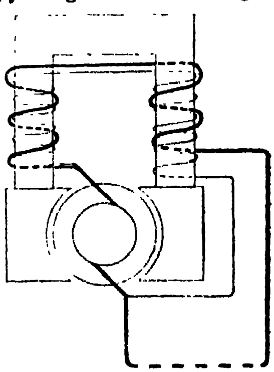

FIG. 4.—COMPOUND WOUND DYNAMO.

By suitably adjusting the series winding, the E. M. F of the dynamo can be kept very constant, even though the resistance of the main circuit vary considerably. (6) *Multipolar Dynamos:* In the earlier days a large per centage of continuous current dynamos were constructed with but two poles.

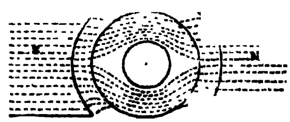

FIG.

With increasing capacities it soon became evident that a bipolar design was unsuitable, and larger numbers of poles were employed. As most dynamos are at present of the multipolar type, the term is now rarely employed. (7) *Nature of the Magnetic Field of a Dynamo:* If the field magnets are excited, but no current is flowing in the armature, the lines of force run as shown in fig. 5, while if the current in

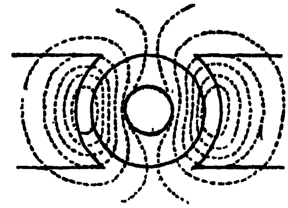

FIG. 6.

the armature were alone flowing, the lines would take the form shown in fig. 6. When the machine is in action, the actual nature of the magnetic field is due to the combined effect of the field magnets and the CROSS MAGNETISATION due to the armature (or ARMATURE REACTION). This is shown in fig. 7. A conductor at A or B is for the moment moving parallel to the lines of force, and not cutting them; hence there is no E.M.F in it at this instant. While a conductor is approaching A (in the direction of the arrow), the current in it is flowing towards the observer, and as the conductor recedes from A, the direction of the current is changed, and it flows away from the observer. The reverse of this occurs at B. The line AB is called the DIAMETER OF COMMUTATION, and the points on the commutator which are in connection with the conductors at A and B are termed the NEUTRAL POINTS. The brushes touch the commutator at these points, and are carried on movable supports, so that the point of contact can be adjusted to follow any variation in the position of the neutral points. In modern dynamos the brushes are by these means set once for all at that position, giving the best results for all loads. The correct position is chiefly dependent upon the magnitude of the reactance voltage, a term of such importance as to justify a brief discussion of its meaning as related to occurrences in the coils short circuited during commutation, and to the occurrences at the brushes. A single armature turn, connected to two adjacent segments, is shown in fig. 8. Prior to coming into the position of short circuit under the brush, it has been carrying a current of, say, 100 ampères in one direction. Immediately after emerging from the position of short circuit, it will be carrying a current of 100 ampères in the other direction. The change must take place sparklessly. With this end in view, the brushes may be set at such a point on the commutator that during the time when the coil is short circuited it will be traversing a magnetic flux of such direction as to tend to reverse the current in the coil. But this tendency must be sufficiently strong to overcome the reactance voltage set up in the coil itself by the decreasing current. This reactance voltage is greater the greater the current in the coil when it arrives at the position of short circuit under the brush; *i.e.* it is greater the greater the load. Hence a stronger reversing field is required the greater the load. At no load a very slight forward lead to the brushes will bring the short circuited coil into a strong reversing field. But at no load no reversing field is required, since there is no current and hence no reactance voltage to be overcome; and if the brushes are given more than a very small forward lead, sparking will ensue in consequence of the current induced in the coil while short circuited, for this current must be broken when the coil leaves the brush, *i.e.* when it emerges from the position of short circuit. At a high load, when a strong reversing field is required to overcome the large reactance voltage, the field has been so distorted by armature interference that a very large lead of the brushes may be necessary in order to bring the short circuited coil into a sufficiently strong reversing field. Hence all that can be accomplished by this so called "electromagnetic commutation" is to choose a brush position as far forward as possible without incurring sparking at no load, and to rate the machine at that load which does not cause sparking in this position, for it is now many years since the practice of permitting different brush positions for different loads has been abandoned. The RESISTANCE of the brush also assists in checking the current originally flowing in the coil. Owing to the unsatisfactory nature of the "electromagnetic commutation," where, as we have seen, the means upon which we rely become weakened in proportion as they should be strengthened, it is sometimes preferable to set the brushes in the geometrical neutral point, and, abandoning all trust on "electromagnetic commutation," merely design the winding with so low a reactance voltage at full load as to preclude the possibility of sparking. (8) *Characteristic Curves:* These are curves showing the relation between the current and the potential difference at the terminals (external characteristic), or the current and the E.M.F. generated in the armature (total characteristic) of a dynamo. They are very instructive and important, and they give a great deal of information about the internal working of the machine. Fig. 9 shows the form of this curve for a SERIES WOUND DYNAMO, the current being plotted along the line OA and the E.M.F. along the line OV. Fig. 10 shows the corresponding curve for a shunt wound machine.

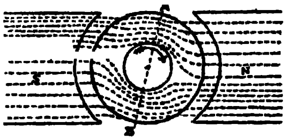

FIG. 7.

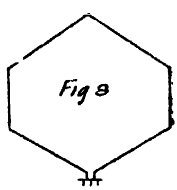

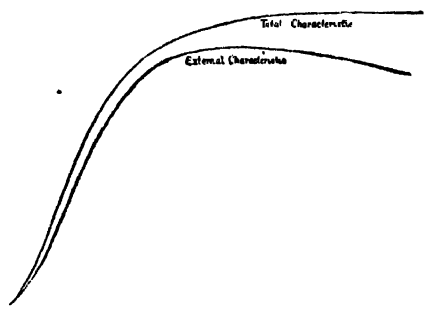

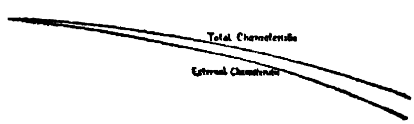

FIG. 10.

The term "Characteristic Curves" is nowadays used in a much wider sense to apply to any curve characteristic of any other feature of the performance of a dynamo. II. THE SINGLE PHASE ALTERNATING CURRENT DYNAMO, *or* ALTERNATOR: If a simple closed circuit be rotated with uniform velocity in a uniform magnetic field, there will be produced in it a varying current whose value at any given instant may be represented by a SINE CURVE (fig. 11). Supposing the coil to be originally at right

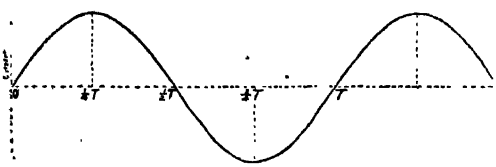

FIG 11.—SINE CURVE.

angles to the lines of force, and to make a complete revolution in T seconds, the changes in the current can be seen from the figure. It commences at 0, rises to a maximum after $\frac{1}{4}$ T seconds, falls to 0 in $\frac{1}{2}$ T seconds, and is then reversed, becoming 0 after T seconds or one complete revolution. In the modern practice T is a small fraction of a second, commonly not over $\frac{1}{50}$, so that each complete change only occupies $\frac{1}{50}$ of a second, and there are 50 complete changes or CYCLES per second. The simplest form of alternator would be a flat coil C (fig. 12) revolving between the poles of a field magnet, which is separately excited. The ends of the coil are attached to two metal rings termed SLIP RINGS, RR, fixed on the shaft, but insulated from it,

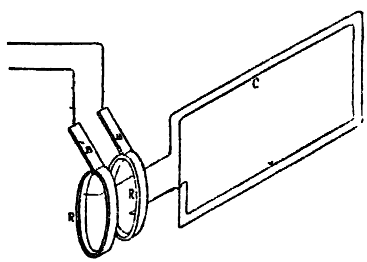

FIG. 12.

and brushes BB collect the current from these rings. The modern commercial machine is, however, of the internal revolving field type, the armature windings being carried on an external stationary ring. III. THE POLYPHASE ALTERNATING CURRENT DYNAMO is now far more widely employed than the single phase alternator. In general construction the two types are identical, except that the external stationary armature carries a number of windings arranged with a given phase displacement from one another. They are generally wound for either two or three phases. The continuous current excitation is carried to the field coils on the revolving field by means of brushes bearing on two slip rings. A machine wound for generating polyphase currents has a much higher capacity than when wound single phase, and is therefore more economical as regards first cost. Polyphase as well as single phase alternators may be, and formerly sometimes were, constructed of the inductor type, in which both the field magnets and the armature coils are fixed. This is

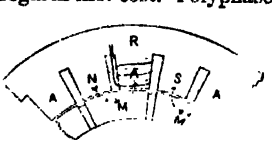

FIG. 13.

shown diagrammatically in fig. 13. Here a large ring of soft iron R has a number of projecting poles, of which those marked A are wound with the armature coils, while N and S are poles of the field magnet, being alternately positive and negative. MM are masses of soft iron rotated by a central shaft. In the position shown lines of force run from the positive pole N to the first armature pole A. As the mass of iron moves to the right the number of lines entering A from N diminishes, until M is immediately under A, when the effect due to N is exactly neutralised by the effect of the negative pole S; as the mass M still moves on, the lines run from A to S, *i.e.* they are reversed. Thus if A be wound with a coil, an alternating current will be produced in this coil. PANCHRONOUS ALTERNATING CURRENT DYNAMOS: All the alternating current dynamos described above must run at synchronous speed. During the last two years there has been independently developed by Latour and Heyland the panchronous type of alternating current generator, in which the revolving field carries a commutator on which are arranged (for three-phase working) three equispaced sets of brushes per pair of poles, three brushes being in conducting connection with the three-phase supply either directly or through transformers. Such panchronous dynamos are self exciting, and while the revolving field is preferably driven in the near neighbourhood of synchronism, as this is the condition corresponding to the best commutation, there is no occasion for the preservation of absolute synchronism, and this feature, together with the feature of self excitation, bids fair to lead to the extended introduction of this class of alternating current dynamo.

Dynamometer, Electrical. An instrument in which the mutual action of two adjacent circuits in which currents are flowing is utilised in order to measure the strength of the currents, or, more exactly, their product, since the mechanical force exerted by one circuit on the other is, generally, proportional to the product of the currents. The principle of the instrument can be illustrated by replacing one pan of a common balance by a flat coil, round which a current can be sent; a second flat coil is fixed to the baseboard of the balance, parallel to and immediately below the first coil. If currents C_1 and C_2 are caused to flow round the two coils, then there will be a force exerted between the two coils proportional to the product C_1C_2. If the direction of the currents be such that this force is one of attraction, it can be balanced by the addition of weights to the other pan of the balance until equilibrium is restored, and the total mass added is proportional to C_1C_2. If the same current circulate round both coils, then the mass added to restore equilibrium is proportional to the square of this current. By an experiment with a known current the value of the constant required to find the value of any current can be found. In SIEMENS' DYNAMOMETER one coil is fixed to the base or stand of the instrument, and the other is suspended, by means of a helical spring or a bifilar suspension, from a torsion head (fitted with a pointer moving over a graduated disc), with the plane of its windings at right angles to that of the first coil. When the current passes, the movable coil tends to turn, and is brought back to its original position by means of the graduated head. The amount which the head is turned is proportional to the couple required to bring the coil back to its original or zero position, and therefore to the product of the currents flowing in the two coils. When the instrument is used to measure a current, the two coils of the instrument are connected in

series, so that the same current flows through both; the instrument then serves as an ammeter. When used as a WATTMETER, or instrument for measuring electrical power (*q.v.*), one of the circuits usually consists of a large number of turns of thin wire, having a high resistance. This circuit is connected as a shunt across the terminals of the apparatus or machine in which the power is to be measured. It therefore receives a current proportional to the potential difference (volts) between the terminals of the machine. The other circuit is of low resistance, and is connected in series to the main circuit of the apparatus, so that the whole current supplying the latter passes through it. The force exerted by one coil of the dynamometer on the other is proportional to the product of the current flowing through the given piece of apparatus and the potential difference at its terminals (amperes × volts), *i.e.* to the electrical power supplied to the apparatus. The dynamometer possesses the great advantage that it can be used for measurements of alternating currents; for if the two coils be so connected that the currents in them are both reversed, the resultant mechanical force between them is unchanged in direction. In measuring alternating current power, however, it is important to ensure that the self-induction of the "pressure" coil, *i.e.* the one in which the current is required to be proportional to the voltage, is kept as small as possible, or, more correctly, that its TIME CONSTANT (*q.v.*) is practically zero. If this is not the case, a lag (*q.v.*) is produced, which introduces a source of error in the measurement.

Dynamo Electric Machines. The older name for the DYNAMO (*q.v.*)

Dynamometer, Mechanical. A mechanical dynamometer is an instrument for measuring the mechanical power which is being transmitted to or from a machine in motion. (1) ABSORPTION DYNAMOMETERS: These absorb entirely the power they receive, usually converting it into heat, which is dissipated into the atmosphere. They are commonly known as BRAKE DYNAMOMETERS, as they depend upon the application of a kind of brake to a rotating wheel, such as the flywheel of an engine, whose actual output of power (termed the BRAKE HORSE POWER) has to be measured. In fig. 1, A is a rotating flywheel, over which passes a belt or band carrying at one end a large weight W, and at the other end a small weight w, or else a spring balance attached to the floor. When the wheel rotates in the direction of the arrow, it will be found that a considerable weight W can be supported in the air with the application of very little force at w. The wheel is then doing work at the same rate as if it were raising a weight $W - w$ by means of a rope coiled round its circumference. If $F = W - w$, and n = the number of revolutions per minute, r the radius of the wheel in feet, then the work done per minute is $F.2\pi rn$ foot-pounds, and $\frac{F.2\pi rn}{33,000}$ is the BRAKE HORSE POWER which the flywheel A is capable of giving out. The belt is often replaced by a thin steel band, the inside of which is faced with wooden blocks which bear on the surface of the wheel. A modification of this form of dynamometer is termed the PRONY BRAKE.

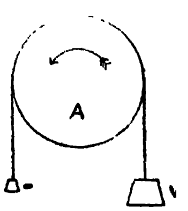

FIG. 1.

(2) TRANSMISSION DYNAMOMETERS: The power transmitted by a rotating shaft is equal to the turning moment or torque multiplied by the angular velocity ($2\pi n$). As the angular velocity is easily measured by a Speed Indicator (*q.v.*), we can find the power if we have any method by which we can measure the torque. An instrument for doing this is known as a TRANSMISSION DYNAMOMETER. The principle upon which one form of this instrument depends is indicated diagrammatically by fig. 2. The power is being transmitted by a shaft A to a parallel shaft B in line with it. To each of these shafts is fixed a radial arm C and D (or discs equivalent to these arms), and these are connected by a spring E, through which the actual force is transmitted. When one shaft is transmitting a torque or a couple to the other shaft, there will be an extension of the spring E; and if this is measured, we can determine the actual torque. Another method of measuring the torque is sometimes applied to electrical motors or small dynamos. It consists in suspending the whole machine bodily in a "cradle" or support carried on knife edges, which are in a line with the axis of the shaft. If a torque be applied to the shaft of the motor while it is running, the whole machine will tend to swing out of the perpendicular, and the moment of the couple required to bring it back to a vertical position can easily be found. This moment or torque is thus equal to the torque applied to the shaft, and therefore the power transmitted to the dynamo is easily calculated. Transmission dynamos are also constructed for measuring tension in a belt. If we can take the difference in tension between the tight or driving side and the loose side of a belt, and multiply this by the velocity of the belt in feet per minute, we shall obtain the power which the belt is transmitting. The velocity of the belt is easily determined from the speed of the pulleys, and the dynamometer has then merely to measure the tension. Two typical ways of doing this are as follows —THE HEFNER-ALTENECK DYNAMOMETER (fig. 3) A and B are two pulleys, one of which is transmitting power to the other. A frame E carries two small pulleys C and D, which can be moved nearer together or farther apart. The frame is placed in such a position that the parts of the belt on both sides of the frame make equal angles with a line through the centres of A and B. The force p, required to keep the frame in this position, is then found. Let T_1 and T_2 be the tensions of the tight and loose sides of the belt; then $p = \sin\theta\,(T_1 - T_2)$; or, if θ is small, $p = \theta\,(T_1 - T_2)$. Hence, by measuring p and θ, $(T_1 - T_2)$ can be found. Another form, due to THORNEYCROFT AND FROUDE, is shown in fig. 4. A pulley A is transmitting power to a pulley

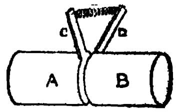

FIG. 2.

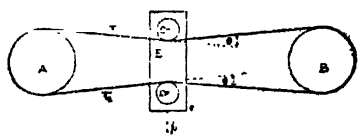

FIG. 3.

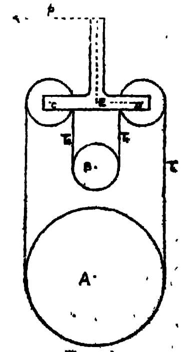

FIG. 4.

B. The belt is caused to pass over two small pulleys whose shafts are fixed at C and D to a frame EF. Then if T_1 indicate the tension on the tight side of the belt, and T_2 the tension on the loose side, the frame E will obviously be pulled over towards the right side, unless a force p be applied to keep it upright. It can easily be shown that $P = 2\frac{ED}{EF}(T_1 - T_2)$, and from this the difference in tension in the tight and loose sides is found at once; and it only remains to determine the speed of the belt to obtain the power which is being transmitted from A to B.

Dyne. The unit of force in the Centimetre Gram-Second System (C.G.S. System). It is the force necessary to give a mass of 1 gram an acceleration of 1 cm. per second per second. It is thus a little more than the force exerted by the earth on a mass of one milligram.

E. The third note of the scale of C.

—— (*Phys.*) The symbol for the COEFFICIENT of SIMPLE ELASTICITY or YOUNG'S MODULUS (*q.v.*) Also used (less frequently) for certain other coefficients of elasticity, for electromotive force, etc.

Eagle (*Her.*) The eagle is generally borne "displayed" (*e.g.* Prussia) or "with wings displayed" (*e.g.* United States), and with beak and claws of a tincture different from the body. When more than one appears upon a shield they are called eaglets.

Ear (*Eng.*) A projecting part through which pass bolts or other fastenings; more commonly termed a LUG.

—— (*Plumb.*) The projection on a pipe by which it is fixed to the wall; used for rain water pipes, waste and soil pipes, etc.

Early English (*Architect.*) One of the periods into which English Gothic architecture is divided. The Early English period extended from about 1189—1307 A.D. The following are some of the characteristics of Early English work: (1) Deeply undercut mouldings. (2) Extensive use of the tooth ornament. (3) Lancet shaped windows and plate tracery. (4) Foliage of a conventional character, usually having stiff stems, and known as stiff leaf foliage. (5) Detached shafts used in the pillars. *See* DECORATED *and* CURVILINEAR.

Earring. A ring, often of precious metal, adorned with gems, worn suspended from a hole bored in the lobe of the ear. The practice of wearing earrings has been common to almost all nations, and amongst many Oriental people they were formerly worn by both sexes. During the reigns of Elizabeth and James I. it was the fashion for men to wear earrings in this country, and the custom still prevails to a limited extent amongst sailors in our own day.

Earth (*Elect.*) From the electrician's point of view the earth is a conductor whose potential is always zero. Any two points in an electrical system which are connected to the earth are therefore regarded as being connected together; hence the earth is utilised in many cases as part of an electrical circuit, *e.g.* in telegraphy, when the earth commonly forms a return wire, and to a certain extent in electric traction, when the return circuit is formed conjointly by the rails and the earth.

Earth Closets. *See* CLOSETS, EARTH.

Earth, Density of. The average density of the earth is found to be 5·5268 times that of water. As this is far higher than the average density of the portion of the earth's crust known to us, it follows that the central portions must have a very much higher density than the outer layers. It has been suggested accordingly that the central part of the earth consists of a mass of the heavy metals.

Earthenware (*Pot.*) The term applies broadly to all pottery which remains, after burning, of an earthy character. It is applied especially to white or cream coloured wares used for inexpensive services. The chief characteristics of earthenware are: softness of glaze; opacity of body, even when made very thin: porosity and absorbency. It is easily chipped and not very durable. *See article* POTTERY AND PORCELAIN.

Earth, Form of (*Astron.*) The earth is an oblate spheroid, *i.e.* a solid produced by the revolution of an ellipse about its shorter or minor axis. The polar semi-diameter (distance of pole from centre) is 3,950 miles, and the equatorial semidiameter is 3,963 miles.

Earth Inductor (*Elect.*) A flat coil which can be turned or spun round about an axis in its own plane. When it is so turned, an electromotive force is induced in the coil by the cutting of the lines of force due to the earth as the coil turns. If the ends of the coil be connected to a ballistic galvanometer, then the throw of the needle is proportional to the number of lines cut by the coil. By observing the throw when the coil is spun through half a revolution, first about a vertical axis, and then about a horizontal axis, a comparison can be made between the horizontal and vertical components of the earth's field.

Earthquake. The violent shock produced at the surface of the earth as a result of the sudden conversion of subterranean water into high-pressure steam. The detonations give rise to a series of wave-like tremors, which progress outwards in all directions from the locality within the earth's crust where the explosions have taken place. A point at the surface directly over this is called the EPICENTRUM, and it is there that the effect first reaches the surface. From that point outward the shocks reach the surface later, and with diminishing effect proportionate to their distance from the epicentrum.

Earth's Field (*Elect.*) The magnetic field (*q.v.*) due to the earth, which behaves as a large magnet. The total intensity is ·438 (dynes per unit pole); the horizontal intensity, ·184; the inclination or dip, 67° 9′, in London. The variations of these "magnetic elements" at different places are shown by maps. *See* ISOGONAL *and* ISOCLINAL LINES, *etc.*

Earthshine (*Astron.*) Near the time of new moon the whole disc is easily visible, the portion on which the sun does not shine having a reddish hue. This light is earthshine, the earth as seen from the moon being then fully illuminated by the sun.

Earth Wax (*Chem.*) OZOKERITE (*q.v.*)

Earthwork (*Civil Eng.*) A general term for cuttings, embankments, etc. In military engineering applied to fortifications constructed by excavation and by the use of the materials so obtained.

Earthy Cobalt (*Min.*) A variety of WAD (*q.v.*) containing a variable quantity of oxide of cobalt. It is a black pulverulent mineral. Cornwall, Leadhills, Saxony, Bohemia, and Missouri and other places in the United States.

Easel. A frame for supporting a picture while being painted; also used for supporting blackboards, etc. A light portable kind of easel used by artists is known as a SKETCHING EASEL.

Easel Picture, Easel Piece (*Paint.*) A picture of comparatively small size, *i.e.* small enough to rest upon an easel whilst being painted. Such pictures are generally highly finished, and admit of close inspection.

Easing Motion (*Cotton Manufac.*) A means of easing the weight on the counter faller of mule, and therefore on the threads.

—— (*Textile Manufac.*) Motions adopted in leno and gauze weaving for slackening or releasing the warp during the formation of what are termed "cross sheds."

Eau de Cologne. A perfume distilled from a mixture of the oils of bergamot, neroli, cinnamon, cloves, lemon, and rose, tincture of musk, alcohol and water. Rosemary and cardamoms are also used sometimes.

Eau de Javelle. An old name for a bleaching solution containing potassium hypochlorite, obtained by passing chlorine into a solution of caustic potash.

Eau de Luce. A remedy for snake and insect bites made from a mixture of mastic spirit, oil of lavender and ammonia; or from oil of amber, alcohol, and ammonia.

Eau Forte. The French term for an etching. Literally, the term applies to nitric acid, with which etchings are generally "bitten."

Eaves (*Build.*) The lower edge of a sloping roof.

Eaves Course (*Build.*) *See* DOUBLING COURSE.

Eaves Gutter (*Build.*) The gutter along the eaves or lower margin of a roof.

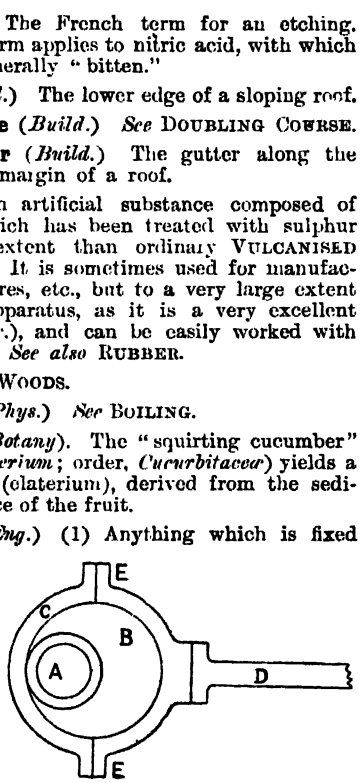
Ebonite. An artificial substance composed of indiarubber which has been treated with sulphur to a greater extent than ordinary VULCANISED RUBBER (*q.v.*) It is sometimes used for manufacturing set squares, etc., but to a very large extent in electrical apparatus, as it is a very excellent INSULATOR (*q.v.*), and can be easily worked with ordinary tools. *See also* RUBBER.

Ebony. *See* WOODS.

Ebullition (*Phys.*) *See* BOILING.

Ecballium (*Botany*). The "squirting cucumber" (*Ecballium elaterium*; order, *Cucurbitaceæ*) yields a purgative drug (elaterium), derived from the sediment of the juice of the fruit.

Eccentric (*Eng.*) (1) Anything which is fixed "out of centre" —*i.e.* which does not rotate about its centre or axis of symmetry. (2) In particular, the disc keyed on a crank shaft "out of centre" which communicates a reciprocating motion to the slide valve, really forming a subsidiary crank. In the figure, A is the CRANK SHAFT, B the ECCENTRIC SHEAVE, C the ECCENTRIC HOOP or STRAP, E the LUGS, D the ECCENTRIC ROD. The distance between the centres of the shaft A and the sheave B is called the ECCENTRICITY or THROW of the eccentric, and equals half the distance the end of the rod D moves, that is, the TRAVEL of the valve.



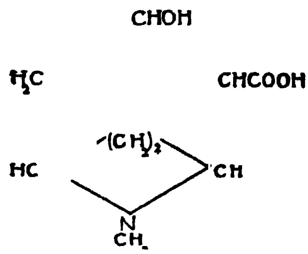
ECCENTRIC.

Eccentric Sheave (*Eng.*) *See* ECCENTRIC.

Eccentric Strap (*Eng.*) *See* ECCENTRIC.

Eccentric Throw Out (*Eng.*) A device for throwing the BACK GEAR (*q.v.*) of a lathe out of action. The back shaft of the gear is carried in collars bored out eccentrically, so that on rotating the collars by means of a suitable handle, the shaft is moved back parallel to itself until the gear wheels which it carries are no longer in contact with those on the mandrel.

Ecgonine (*Chem.*) White solid crystallising in prisms; melts at 198°, with decomposition. Easily soluble in water; less soluble in alcohol; insoluble in ether. It is lævorotatory. It is an acid and also an alcohol. For its preparation and some of its important reactions *see* COCAINE. Besides these may be mentioned the following: Distilled with zinc dust it yields methylamine (CH_3NH_2) and α-ethyl pyridine,



ECGONINE.

CH

HC CH

HC C . C_2H_5.

NH

Oxidised with alkaline permanganate the methyl group (CH_3) is replaced by hydrogen yielding nor-l-ecgonine.

Echinus (*Architect.*) An ovolo moulding enriched with the egg and dart ornament. The ovolo of the Doric capital is also known as the echinus. *See* OVOLO *and* EGG AND DART.

Echo (*Sound*). A sound which is reflected back to the ear of the observer by some large solid object.

Eclipse, Lunar (*Astron.*) When the sun, earth, and moon are in a straight line, or nearly so, the earth acts as a screen, wholly or partially cutting off light from the moon, which is said to be eclipsed. A lunar eclipse can be seen from one half the earth's surface.

Eclipses, Number of (*Astron.*) In one year seven eclipses can occur, either five solar and two lunar, or else four solar and three lunar. The least possible number is two, and these will be solar eclipses. Any series of eclipses recurs after a period of eighteen years eleven days. This interval was known to the Chaldeans, who termed it the Saros.

Eclipse, Solar (*Astron.*) The moon cuts off the sun's light from the earth by wholly or partially obscuring the sun's disc when in a line (or nearly so) between the earth and the sun. The sun is then said to be in a state of total or partial eclipse. If the

dark shadow occupies the centre of the sun's disc, leaving a bright ring all round, the effect is called an annular eclipse.

Ecliptic (*Astron.*) The great circle on the celestial sphere along which the sun's apparent path always lies.

Economisers (*Eng.*) Various types of apparatus for heating the boiler feed water before it enters the boiler, by utilising the waste heat in the flue gases. Generically, any plant which, by economising heat, increases the weight of water evaporated per pound of fuel. *See also* BOILERS.

Economy Coil (*Elect. Eng.*) A CHOKING COIL (*q.v.*)

Ectype (*Art*). An impression of a medal or other object in wax or other plastic substance: a reproduction.

Eddy Currents (*Elect.*) Currents produced entirely within a mass of metal through the movement or alteration in number of the magnetic lines of force passing through it. Eddy currents tend to occur in the cores of transformers, pole pieces of the field magnets of dynamos, etc. They are reduced to a minimum by LAMINATION (*q.v.*) They are often termed FOUCAULT CURRENTS.

Eddy Winds (*Meteorol.*) *See* WHIRLWINDS.

Edge (*Silk Manufac.*) *See* LIZIER.

Edge Coal (*Geol.*) The Lower Carboniferous coal seams of Midlothian happen to occur along a zone where the strata have been thrown into the limb of an earth fold which is steeply inclined. These coals are commercially important, and it is often required to distinguish them from the Upper Carboniferous coal seams which are worked in the same area: hence the name. It is merely a local term.

Edge Runner. A form of mill used for grinding or crushing many materials, such as white lead and other pigments, dry soap, putty, mortar, pulp, paper, etc. It consists of circular stones or rollers mounted so as to run on their edges in a circular hopper or pan, into which is placed the material to be ground. In some forms the pan is stationary and the stones revolve, while in others the pan also revolves.

Edinburgh Wheel. A type of candle-making wheel by which the wicks on the dipping frames could be immersed in the tallow bath in rotation without detaching the frames from the wheel at every dipping. Virtually superseded by the moulding machine. *See also* CANDLE.

Edinol (*Photo.*) This substance belongs to the class of so-called rapid developers, and possesses the advantage over some of them of greater solubility and good keeping qualities. It develops images very free from fog, and is capable of considerable modification to suit various kinds of work.

Edison's Phonograph. *See* PHONOGRAPH.

Eduction (*Eng.*) The EXHAUST (*q.v.*) or leading of the steam, etc., from a cylinder after the stroke is completed.

Eduction Port (*Eng.*) The channel for the escape of the steam, usually termed an EXHAUST PORT.

Edulcoration (*Chem., etc.*) Washing a substance to remove soluble impurity.

Eel (*Zoology*). The eel (*Anguilla vulgaris*) is common to the greater part of Europe.

Effective Current *or* **Voltage** (*Elect. Eng.*) *See* VIRTUAL CURRENT *and* VIRTUAL VOLTAGE.

Effective Heating Surface (*Eng.*) The part of a steam boiler which has water on one side and the fire (or hot gases) on the other.

Effective Span (*Build.*) The horizontal distance between the centres of the bearings of a girder.

Effects (*Chem. Eng.*) The separate vacuum units of a multiple effect evaporator. *See* EVAPORATORS.

Efficiency (*Phys., Eng.*) In general, the ratio between the useful energy obtained from a particular machine and the energy put into it. Thus if power to the amount of 1,000 watts be supplied to a transformer, and 950 watts be obtained from it, the efficiency is 95 per cent., or ·95.

Efficiency of Heat Engines. The efficiency of a heat engine is the ratio of the work done to the heat supplied to it; that is, the fraction $\frac{W}{H}$, where W is the work done and H the amount of heat supplied (W and H must be measured in the same units). If the original temperature of the working substance (steam or other gas) at the commencement of the stroke of a perfect engine be T_1, and at the end of the stroke be T_2, then the efficiency is $\frac{W}{H} = \frac{T_1 - T_2}{T_1}$.

Efflorescence (*Chem.*) Salts which crystallise with water of crystallisation have a definite vapour pressure: when the vapour pressure of such a salt exceeds that of the atmospheric aqueous vapour, the salt, when exposed to air, will lose part of its water of crystallisation; this phenomenon is called efflorescence. The word is also employed in quite a different way to denote the appearance of a white powder on a damp wall or other porous surface.

Effrayé (*Her.*) A horse "salient" or rearing, as in fear.

Effusion of Gases (*Phys.*) The passage of a gas through a porous partition or small opening; the rate of effusion is directly proportional to the square root of the difference of pressure on the two sides of the partition, and inversely proportional to the square root of the density of the gas. *See also* ATMOLYSIS.

Egg and Dart, Egg and Tongue, Egg and Anchor (*Architect.*) A repeating ornament, carved on an ovolo in classical architecture, resembling a series of eggs separated by darts. The Greek egg and tongue, like all other Greek ornament, is much more refined and graceful than the Roman examples.

Eggertz's Test (*Met.*) A colorimetric test for the estimation of combined carbon in steel and wrought iron.

Egg Shell (*Pot.*) Porcelain of extreme thinness and delicacy, originally made in China.

Eggshell Gloss (*Dec.*) *See* BASTARD FLATTING.

Egg Sleeker (*Moulding*). A tool with a rounded face, used for smoothing hollows in a mould.

Egyptian (*Typog.*) A heavy or fat faced style of type (**EH**) now rapidly being replaced by more modern and graceful styles.

Egyptian Blue (*Archæol.*) A crystalline blue pigment used by the Romans. Examples occur in some of the frescoes in the Vatican.

Egyptian Jasper (*Min.*) A banded brown variety of JASPER, an impure opaque form of silica.

Eidograph (*Surveying*). An instrument for reducing drawings to a smaller scale.

Eighteenmo (*Print.*) A sheet of paper folded into eighteen leaves; the same as octodecimo. Usually written 18mo.

Eighth Bend (*Eng.*) A bent pipe whose length is one-eighth of the circumference of a circle; used for joining two pipes which make an angle of $22\frac{1}{2}$ degrees with one another.

Eight to Pica Leads (*Typog.*) Thin leads measuring in thickness eight to one pica, used by printers to put between lines of type to white out or lengthen the printed matter.

Eikonogen (*Photo.*) The sodium salt of amido-β-naphthol sulphonic acid ($C_{10}H_5NH_2OHSO_3Na$). This developer is valuable in portraiture or where soft negatives are required, as well as for snapshot work, and for use with orthochromatic plates. Mixed with hydroquinone it is a favourite with many for general use.

Elæis (*Botany*). A genus of palms, consisting of two species, one in tropical America, the other in Africa. These palms yield a valuable oil. *See* PALM OIL.

Elaidic Acid (*Chem.*), $\begin{matrix}C_8H_{17}\\H\end{matrix}\!>C:C<\!\begin{matrix}(CH_2)_7COOH\\H\end{matrix}$. A white solid melting at 51°. It is isomeric with oleic acid, and is formed from it by the action of nitrous acid; it forms a dibromide, and is reduced to stearic acid by hydriodic acid. Its glyceryl ester is called ELAIDIN, and is formed from olein by the action of nitrous acid, just as elaidic acid is formed from oleic acid.

Eland (*Zoology*). A well known South African antelope, *Orias canna*, whose hide and flesh are valuable.

Elasmobranchii (*Zoology*). A subclass of fishes, comprising the sharks, dogfishes, skates, and rays. They are characterised by a cartilaginous (not bony) skeleton, tooth scales on the skin, absence of a gill cover and swim bladder, etc.

Elastica (*Phys.*) The curve assumed by a uniform strip of elastic material, subject to two equal and opposite forces acting in the same straight line. Also called the ELASTIC CURVE and LINEA ELASTICA. A bent bow is an example of this curve, and various other forms can be obtained by bending a steel wire or watch spring.

Elastic Bitumen *or* **Elaterite** (*Min.*) A soft and elastic hydrocarbon of a brownish black colour, with a peculiar characteristic odour. From Derbyshire, Edinburgh, France, Switzerland, etc.

Elastic Fatigue (*Phys., Eng., etc.*) A falling off in value of the elasticity (*q.v.*) of a body when it has been subjected to a long continued stress or succession of stresses. The effect is very marked when the stresses have been alternately applied and removed. The exact nature of the changes which occur is obscure. There may be definite molecular changes, or the results may be due to the development of minute flaws in the material.

Elasticity (*Phys., Eng.*) That property of matter in virtue of which it offers resistance or opposition to external forces which tend to change its form or dimensions. It is necessary to notice that this definition does not denote quite the same idea as is attached to the word elasticity in ordinary use; for instance, a piece of steel, which offers a much higher resistance to change of shape than indiarubber, is (in scientific language) more elastic than indiarubber.

Elasticity (*Cotton Manufac.*) The amount of stretch or pull the yarn will stand before breaking—a very important factor in warp yarns. Testing machines are employed to ascertain the elasticity and breaking strain.

—— (*Woollen Manufac.*) A term applied to the staple of wool, the yarn, and to the woven fabric.

——, **Coefficient of** (*Phys., Eng.*) The ratio of the stress set up in a body, to the strain which produces it. *See* STRESS *and* STRAIN. Expressed as an equation, this gives

$$\text{Coefficient of Elasticity} = \frac{\text{Stress}}{\text{Strain}}.$$

A coefficient of elasticity is thus equal to the stress which produces unit strain, and is measured in the same units as the stress.

Elasticity of Bulk *or* **Volume Elasticity.** The stress in this case is the increase of pressure per unit area; the strain is the diminution per unit of volume. If a pressure p be applied per unit area of a body, and the volume be diminished by an amount v; then if the original volume be denoted by V, the strain is $\frac{v}{V}$, and we get

$$\text{Coefficient of Bulk Elasticity} = p \div \frac{v}{V} = \frac{pV}{v}.$$

Gases and liquids can only offer resistance to change of volume and not to changes of shape. From the definition of elasticity (*q.v.*) it is therefore evident that they can possess bulk elasticity only.

Elasticity of Compression (*Phys., Eng., etc.*) In the case of simple compression the stress is the pressure applied per unit of area, and the strain is the diminution per unit of length (measured in the direction of the stress). Thus, if a pressure p be applied to the end of a bar of cross section a, the stress is $\frac{p}{a}$. If the original length of the bar be L and the amount of compression be l, then the strain is $\frac{l}{L}$. Then if E be the coefficient of elasticity of compression, we get

$$E = \frac{\text{Stress}}{\text{Strain}} = \frac{p}{a} \div \frac{l}{L} = \frac{pL}{al}.$$

This result is similar to that obtained for the elongation of a body (*see* ELASTICITY OF ELONGATION), and the coefficient is in very many cases the same in amount.

Elasticity of Elongation (*Phys., Eng., etc.*) In the case of simple elongation the stress is the stretching force per unit area; the strain is the elongation per unit length. If a bar of length L and cross section a be stretched by a force p till its length be increased by an amount l, the stress is $\frac{p}{a}$ and the strain is $\frac{l}{L}$. Then the coefficient of longitudinal elasticity, or, as it is often called, the value of YOUNG'S MODULUS, for the material is

$$E = \frac{\text{Stress}}{\text{Strain}} = \frac{p}{a} \div \frac{l}{L} = \frac{pL}{al}.$$

The value of E is given in units of force per unit of area. For engineering purposes it is usually given

in tons per square inch. The values for some of the most important materials are as follows:

	Tons per Square Inch.	Dynes per Square Centimetre.	
Steel (tempered)	16,000	25	10^{11}
Steel (mild) .	13,200	20·8	10^{11}
Wrought Iron .	18,000	20·5	10^{11}
Cast Iron . .	6,250	9·8	10^{11}
Copper (drawn) .	7,880	12	10^{11}
Brass (wire) . .	6,350	10	10^{11}
Teak	1,070	1·76	10^{11}
Ash	717	1·11	10^{11}
Oak	655	1·01	10^{11}

Elasticity of Flexure. The coefficient of elasticity concerned in the simplest cases of bending is Young's Modulus, or the elasticity of elongation (*q.v.*) *See also* BEAM.

Elasticity of Gases (*Phys.*) The only kind of stress to which a gas can be subjected is the increase of pressure per unit area; the strain produced by this stress is measured by the diminution which each unit of volume of the gas undergoes. The ratio of stress to strain depends upon thermal conditions, *i.e.* whether any heat is allowed to enter or leave the gas during the operation. If no heat enter or leave, the change which occurs is adiabatic (*q.v.*), and the value of the elasticity is then obtained from the adiabatic equation, PV^{γ} = constant. This gives $E = \gamma P$. If the change is isothermal, the ratio is determined by Boyle's Law: PV = constant, and we get $E = P$. Thus in one case the elasticity of a gas is equal to the pressure; in the other case, to the pressure multiplied by γ, which is the ratio of the specific heats (*q.v.*)

Elasticity of Shape (*Phys.*) *See* TORSION *and* RIGIDITY.

Elastic Limit (*Eng.*, *Phys.*) The extent to which a body may be deformed or strained, and still retain the power of completely recovering its original shape when the stress is removed The greatest strain and stress which do not exceed this limit are often termed the ELASTIC STRAIN and ELASTIC STRENGTH of the substance. If the elastic limit be exceeded, the body does not recover its previous form on the removal of the stress, but retains a permanent alteration of form or a "set."

Elastic Packing (*Eng.*) PACKING (*q.v.*) made of rubber covered over by canvas.

Elastic Strain (*Eng.*) *See* ELASTIC LIMIT.

Elastic Strength (*Eng.*) *See* ELASTIC LIMIT.

Elbow (*Eng.*, *etc.*) A short length of pipe bent at a sharp angle.

—— (*Mining*). A sharp bend in a vein or lode.

Elbow Lining (*Carp.*, *etc.*) The framing at the sides of a bay window or recess below the nosing.

Elbow Point (*Print.*) A press point made upon an elbow to facilitate pointing in 12mo or 18mo works.

Elbow Press. A special form of screw press for expressing tallow, waxes, and oils from animal tissue and vegetable products. Intermediate between the old types of lever and wedge presses and the modern hydraulic press.

Elder (*Botany*). The elder (*Sambucus niger*; order, *Caprifoliaceæ*) is of value on account of its fruit, flowers, and the pith. The fruit is made into a wine; the flowers are used in making ointment and a "water." *See also* WOODS.

Electrical Lines of Force. *See* LINES OF FORCE.

Electrical Machine. A device by which charges of electricity can be imparted to objects or differences of potential set up. The name is, however, usually confined to machines consisting of revolving plates (or cylinders) of glass or ebonite, which are electrified by friction (frictional machines) or by induction resulting from a small initial charge. *See* WIMSHURST, VOSS, *and* HOLTZ MACHINES.

Electric Automobiles. A light carriage propelled by a continuous current motor, which is supplied with power by a battery of storage cells. These carriages are very smooth and silent in action, but the great weight of the storage cells prevents them from carrying sufficient power for long runs. On this account they are only suitable for town use as a "Runabout," never moving far from places at which the storage battery can be recharged.

Electric Charge. A definite quantity of "electricity" or of "electrification." Maxwell remarks, "The electrification of a body is a physical quantity, capable of measurement. We are therefore entitled to use language fitted to deal with electrification as a *quantity* as well as a *quality*, and to speak of any electrified body as *charged with a certain quantity* of positive or negative electricity." *See also* ELECTRICITY.

Electric Discharge. The dissipation of electricity or loss of charge from a body. It may be accompanied by visible phenomena, such as sparks, a glowing appearance of the surrounding gas, etc., or it may be of a nature not evident to the senses, and only to be detected by electrical means. *See* DISCHARGE.

Electric Furnace. *See* FURNACES.

Electric Ignition. *See* IGNITION.

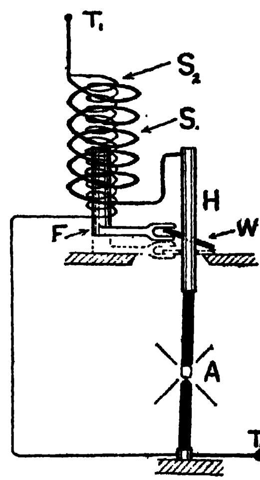
Electric Image. An imaginary electrified point (or system of points) situated on one side of a surface, and producing on the other side the same electrical action which the actual electrification of that surface produces. These imaginary points correspond (to some extent) to virtual images in optics, but their positions are not governed by the same laws.

Electricity. Early writers on the nature of electricity supposed it to be either a fluid of peculiar properties or else two fluids whose properties were complementary to each other or of opposite kinds; for example the ONE FLUID THEORY of Franklin, and the earlier TWO FLUID THEORY of Symmer. Later physicists arrived at the conclusion that whatever electricity might be, it was not a material substance. This theory was based upon many considerations arising from the existing knowledge of the properties of "material substances" or "matter." As an alternative it was suggested that electricity was a form of energy, but this proved untenable. Professor Lodge (now Sir Oliver Lodge) stated, in *Modern Views of Electricity*, published in 1889, that "Electricity may be a form of matter; it is not a form of energy." Since this was published, a vast amount of experimental work has extended our knowledge of the properties of matter under new conditions; these researches include the phenomena connected with the passage of electricity through gases, the various newly discovered forms of radiation, and the investigation of the properties of radio-active bodies. As a result of these researches it has been found by Professor J. J. Thomson that positive electrification is always

associated with ordinary matter, while negative electrification is not necessarily so, but may be associated with bodies very much smaller than the smallest particle of ordinary matter previously recognised, *i.e.* the atom of hydrogen. To these bodies the name CORPUSCLE or ELECTRON has been given. An assemblage of these electrons corresponds to the electric fluid, and a negatively charged body is one to which a number of electrons have become attached. An electric current is a stream of electrons, and a substance which conducts electricity is one through which the electrons can move freely. To account for positive electrification it is necessary to suppose that every neutral or unchanged atom of ordinary matter contains, or is associated with, a definite number of electrons, together with a positively charged nucleus. If this atom be deprived of some of its electrons, it becomes positively electrified; if one or more electrons (over and above the original number) become attached to it, it is negatively electrified. The effective mass of such a charged atom will not be very different from that of the uncharged atom; hence in a gas under ordinary conditions of pressure, the positive and negative ions will not differ appreciably from each other in mass. But when the electric discharge is sent through gases at very low pressures, free electrons are projected from the cathode, and it becomes possible to measure their velocity, and the ratio of the mass of each to its charge. Other methods enable the charge itself to be measured, and as a result it is found to be the same as the charge carried by the hydrogen ion in the electrolysis of solutions; this is $3{\cdot}4 \times 10^{-10}$ electrostatic units, while the mass of the electron is about $\frac{1}{1000}$ of that of an atom of hydrogen. The action of electrons is capable of accounting not only for electrical and magnetic phenomena, but also for many of the well known physical and chemical properties of matter; thus the Mass, Inertia, Valency, the position of elements in the Periodic System, and the character of their spectra can all be referred to the behaviour of electrons attached to or separated from the atom of elements. In addition to these far-reaching results, the phenomena presented by radio-active substances, such as radium, can be traced to the properties of electrons. It must be pointed out that our definite experimental knowledge only applies to *negative* electricity; the nature of positive electricity (and of the positively charged particles projected from Radium) is still absolutely unknown, and the ideas referred to above are merely speculative.

Electricity, Atmospheric (*Meteorol.*) The electrical state of the atmosphere varies in amount; but electrification is always present, and may easily be detected by ELECTROSCOPES (*q.v.*) connected to kites, etc., by a conducting string or wire, as in Franklin's early experiments. The POTENTIAL (*q.v.*) of the air is usually positive. In a thunderstorm there are sudden and violent changes both in sign and potential.

Electric Lighting. The energy of an electric current was first transformed into light by the agency of the "arc" or spark. Humphrey Davy found in 1800 that two touching points in a circuit carrying a current gave a flash on being separated. The brilliant whiteness of the spark produced on separating carbon points suggested the commercial value of this phenomenon, and in 1810 Davy exhibited at the Royal Institution a flame maintained between the ends of two horizontal carbons 4 in. apart. From the shape of the flame—that of a bow or "arc" of light—the name was derived which has since characterised this method of lighting; though, by the now general practice of placing the rods vertically above each other, the distinctive form has disappeared. Arc lamps are constructed for use on both continuous current and alternating current systems. In the latter case the frequency (or number of double reversals of current direction per second) must not be less than fifty, or else the lamps flicker objectionably. They may be grouped "in series," the same current passing through them one after another; "in parallel" or side by side along the feeding circuit, each working independently of the rest so long as the electrical pressure remains steady; or "in series parallel," a number of parallel circuits of lamps in series. In the first class each lamp should have an automatic short circuiting device, so that the breakdown of one lamp does not extinguish the rest. In the second and third classes each lamp should be bridged by an equivalent resistance, to be automatically thrown in if the lamp fails, to maintain the steady burning of the rest. An arc is in a state of unstable balance: if a slight increase be given to the current, the resistance of the arc to the passage of current becomes less, the area of the arc being proportional to current strength, and the current will therefore build itself up indefinitely. Conversely, a diminution of current produces further reduction till the arc goes out. It was therefore speedily recognised that unceasing regulation was necessary, this being performed by adjusting the *length* of the arc. This was at first effected by hand, and for all purposes where the operator is in constant attendance (as with searchlights) this is still done. Automatic regulation was introduced by Wright in 1845, while Staite first used the current itself to regulate the carbons in 1848. The functions of a modern arc lamp mechanism are to separate the carbons (after bringing them together if they do not close by gravity when the current is switched off), to steadily maintain the distance between the carbons so that the illumination is kept constant, to feed one or both carbons towards each other as their ends are burnt away, and after switching off to leave the lamp ready to restart whenever required. The control is effected by balancing the pull of one or more electromagnets in the lamp circuit against gravity, the pull of a spring, or both combined. A typical mechanism for these operations is shown, reduced to its simplest form, in the diagram. The current passes from one terminal T_1 through the series (thick) coil S_1, the top carbon holder H, the two carbons at the junction of which (A) the arc is formed, to the other terminal T_2. The carbons are initially in contact. A strong current, passing through this closed circuit, energises the series coil, which pulls the plunger-piece F upwards.



ARC LAMP.

This has a fork engaging with a washer W, which is a loose fit on the rod holding the carbon. If slightly tilted by the fork, it grips the rod, and if F be further raised, the upper carbon is lifted, striking the arc. A shunt coil of fine wire S_2 also acts on the plunger in an opposite sense to the series coil. If the arc grows too long, *i.e.* its resistance is raised, the current becomes stronger in the parallel shunt coil, weakening the pull on the plunger and allowing the washer to fall back on its support as shown by dotted lines, the rod then slipping till the arc resistance is again low enough. This "differential" winding is essential in series arc circuits, where the current is practically constant whatever fluctuations each arc makes, the series coil simply striking the arc. On parallel and series parallel circuits, though used, it is not essential, a series coil being sufficient. Other mechanical devices are used to feed the carbons, the clutch type being here described for its extreme simplicity. As all control mechanisms have a little inertia, they do not respond instantaneously to sudden fluctuations of current; in parallel circuits, therefore, "steadying resistances" (for direct current arcs) or "choking coils" (for alternating current lamps) must be provided to damp these fluctuations. In series circuits these latter devices are unnecessary, as the dynamo is specially built to take care of the fluctuations. The above adjuncts to the lamp are usually contained in the cylindrical case surmounting it, or, where their bulk is prohibitive, in a wall box or the base of the supporting lamp post. The candle power of an arc varies with the angle to the axis of the carbons at which the measurement is made. In direct current lamps the light is thrown well downwards, giving a maximum at about 60° from the axis. Alternate current lamps throw their light almost equally up and down, and hence must be provided with reflectors. The average candle power (taken from a large number of measurements all round the lamp) of an ordinary street lamp ("open type") is from 525 to 875, the current, if continuous, being from 6 to 10 ampères, or from 10 to 15 ampères if alternating. If the current is less than these minima, the proportion of cooling surface of carbon to energy of the arc is much increased; the arc flickers violently and goes out. An 875 candle power lamp requires about 0·6 horse power, delivered at the carbons. The carbons themselves are gradually consumed by the arc, requiring replacement in eight to ten hours. The arc light is admirably adapted for public lighting, and in the form of Jablochkoff's "candles" was first used for this purpose in 1876 to light the Avenue de l'Opera, Paris, and the Thames Embankment, London. Recent tests by the Westminster City Engineer show that the cost per candle power per annum (including maintenance, sinking fund, and interest) for arc lamps averages 11·76*d.* The best figure for gas (Sugg's high pressure) is 8·7*d.*, and with ordinary incandescent mantles 18·18*d.* In 1894 "enclosed" arcs were commercially introduced, the arc burning within a small globe of clear or opalescent glass, the latter giving a more diffused light, but absorbing about 15 per cent. In some cases this is enveloped by a larger globe. The outside air is largely excluded, and after a few minutes' burning, the arc is surrounded by carbon monoxide, an inert gas. As a result, combustion is slower, the carbons lasting from 100 to 120 hours; the voltage across carbons can be raised to 150, though 80 volts (on 100 volt mains) are generally used; the light changes from white to violet as the voltage increases; the temperature within the globe rises, rendering the cooling surface less effective, and allowing the use of smaller currents. The usual value is 5 ampères, but recently "midget" lamps have been made of sufficiently small power to comfortably light an ordinary room. Efforts have lately been made by mixing salts of metals, such as calcium fluoride and cryolite, with the carbon, to change the colour of the light; the Bremer arc, giving a reddish yellow flare, being the best known example. This lamp is also remarkable as reverting to the true "arc," a flame being projected downwards—*i.e.* in the direction of maximum use—from the carbons (which are each tilted at an angle of 15° to the vertical) by the action of an electromagnet. Almost simultaneously with the practical development of the arc light came the initiation of the glow lamp—an electric conductor raised to incandescence, but not volatilisation, enclosed in a glass bulb in which a very high vacuum is obtained. In 1858 Jobart proposed to use a small carbon in a vacuum, but we owe our present lamp principally to the work of Edison and Swan between the years 1877 and 1880. Platinum wire was first used, but was liable to sudden rupture if overheated. Thin carbon wires prepared from parchmentised cellulose are now employed. The cellulose thread is formed by treating cotton thread with strong sulphuric acid, or by dissolving cotton wool or Japanese paper in zinc chloride, the viscous solution being then squirted through fine jets into alcohol, which hardens the thread. This parchmentised filament is wound on carbon blocks moulded to the required shape, and placed in a crucible packed with plumbago, where it is maintained at a white heat for twenty-four hours. The carbonised filament is next attached to leading-in wires of platinum either by carbon cement or electrically deposited carbon, being then immersed in a liquid or gaseous hydrocarbon (*e.g.* benzoline) and a strong current "flashed" through it, making it instantaneously incandescent. In this state it receives a deposit of hard carbon, which adheres more especially to the thinner (or hotter) parts of the wire, rendering it of uniform thickness. The filament is now sealed (by the leading-in wires) into a glass bulb provided with an extension tube, which is afterwards fused on to the exhaust tube of a mercury air pump. After an almost perfect vacuum is obtained in the bulb the latter is melted off the extension tube and tested for vacuum, candle power, and voltage. The cap which fits the lamp holder is now fixed to the bulb by plaster, and figures for voltage and candle power etched on the glass. Difficulty in standardising the pressure of supply was found, but practice ultimately resolved, itself into supplying at 100 to 110 volts as being most suitable to the lamp's requirements. Of late years, however, lamps have been commercially produced for pressures up to 240 volts, and the importance of this advance is measured by the fact that a given quantity of electricity at 200 volts can be distributed over an area four times as large as that available with 100 volts, with the same loss. The glow lamp is not so efficient as the arc, one 16 candle-power lamp requiring about 0·085 horse-power; but the light is more agreeable, and much smaller lamps can be used, the usual candle power per lamp being 8, 16, or 32. Within the last three years an important departure has been made by the introduction of the Nernst lamp, which is essentially a thin rod of highly refractory earths of rare metals similar to those used in the Welsbach gas mantle. Such a rod is a non-conductor when cold, but on

being moderately heated permits the passage of an electric current, which then renders it brilliantly incandescent. The filament glows safely in air, being merely surrounded by a glass wind shield. A spiral of this wire cased in enamel surrounds the rod, and is in circuit on first switching the current on to the lamp, becoming heated to bright redness and imparting heat to the refractory filament. As soon as the latter is warm enough to conduct the current a small electromagnet switches the heater out of action, replacing it when the current is switched off. The resistance of the rod to passage of current becomes less the stronger the current which heats it, and if left to itself the rod would soon burn out. The current is therefore first passed through a loop of iron wire, the resistance of iron *increasing* the stronger the current flowing through it. By a proper proportioning of the filament and iron, a steady light, and durability of the lamp, are ensured. The average life of the filament, which is replaceable at small cost, is 475 hours. The efficiency of the lamp is very nearly equal to that of the arc; it gives a soft white light, and is obtainable in candle powers of from 50 to 2,000. The cost of burning, including renewals, is approximately 11*d.* per 1,000 candle power hours, as against, say, 15*d.* for ordinary glow lamps.—J. A. S.

Electric Motor. *See* MOTORS, ELECTRIC.

Electric Power. The rate at which electrical energy is supplied or developed. It is proportional to the strength of the current and also to the electromotive force. The unit in which electrical power is measured is the work done in one second by a current of 1 ampère supplied at a potential difference of 1 volt, and is termed the WATT. One watt = 10^7 ergs per second; 746 watts = 1 horse power. When the current is continuous, the power is equal to the product VC, where V is the difference of potential in volts between the terminals of the part of the circuit in which the power is being measured, and C the current, in ampères, flowing through it. C and V are respectively measured by any suitable form of ammeter and voltmeter, the former being joined up in series with the main circuit, and the latter being joined up as a shunt across the terminals. If the current is an alternating one, the power supplied is equal to the product VC cos ϕ, where V and C are the virtual values (*q.v.*) of the volts and ampères, and ϕ is the angle of lag. Alternating current power can be measured by means of a dynamometer or wattmeter, or by certain special combinations of instruments.

Electric Screen. A closed surface of conducting material, connected to earth and therefore at zero potential. An object placed inside such a surface is entirely protected from the action of any external electrified body.

Electric Traction. The history of electric traction in early days is a record of protracted struggle under adverse conditions, but later the record is one of progress and success that is almost unequalled. The date of its inception cannot be rigidly fixed, but the chief landmarks in its history are briefly as follows: The introduction of the underrunning trolley by F. J. Sprague in 1886. The attention given to the design of cars by Brill, resulting, a little later, in the consideration of the truck as a separate and most important part, not subservient to the car body, as was formerly more or less the case. The inception of the SERIES PARALLEL CONTROLLER by Hopkinson, and its improvement by Condict and Thomson into the important piece of switching apparatus that we now know, without which economical electric traction would be impossible, as starting and regulation of speed would have to be performed by the introduction of wasteful series resistances. Improvements in motors, track construction, and other details have, of course, been responsible for a great measure of the present success of electric traction; and as practically all the principal firms have contributed to their gradual evolution, they do not belong to any particular date or name. At the present day the recognised methods of electric traction in practical use are: (1) ACCUMULATOR; (2) SURFACE CONTACT; (3) CONDUIT; and (4) OVERHEAD systems. Of these the last is by far the most popular. The first, in which the motive power is carried on the car in the shape of charged accumulators, may be dismissed in few words. Despite its sundry advantages, such as flexibility and self-containedness, it has been proved to be commercially impossible, owing to its low efficiency and the rapid deterioration of accumulators when exposed to perpetual shaking and jarring. The advent of a lighter, stronger, and more efficient cell is the only thing that can popularise this form of traction. The SURFACE CONTACT system, on the other hand, has possibilities; indeed, several inventors claim to have solved the problem of transmitting power to a moving car, without having overhead or underground conductors. Every few feet down the centre of the track are laid contact blocks, slightly higher than the surrounding road surface; and these are connected through adjacent automatic switches to the feeder cables. On the bottom of the car is carried a collecting SKATE, which, rubbing on the contact studs, conveys the current to the motors, the return path being through the wheels and rails. The essential feature of the system is that the studs should only be alive when directly under the car; it therefore follows that the latter must have an alternate closing and opening influence upon the underground switches, and this is effected, according to the system, either by electrical, magnetic, or mechanical means. Fig. 1 shows a

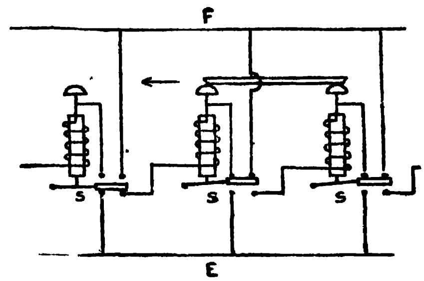


FIG. 1.—VEDOVELLI SURFACE CONTACT SYSTEM.

typical case of electrical working due to Vedovelli: SSS are the automatic switches, F the feeder, and E the earth return. Upon the skate touching a leading stud, the latter is placed in electrical connection with the trailing one; consequently a current flows through the magnetic switch coil of the former, lifting up the switch from the two bottom contacts upon which it rested, closing it as shown, and passes away to earth through the contacts of the next switch of the series. When the skate breaks contact with the stud, the switch opens, as the current that was holding it in position by the aid of the electromagnet is stopped. Magnetic methods are usually

simpler and more reliable than the above. Generally a magnet excited by the line current or a separate battery of cells is carried underneath the car, and this suffices to actuate the stud-switching mechanism. Mechanical operation appears to be the most reliable if the design is good. It may be effected among other ways by a plough running in a shallow conduit, operating the switches by mechanical means as it passes. Surface contact electric traction has of late received an impetus, owing to the introduction of sundry improvements tending towards greater reliability; the consensus of opinion is, however, against it as a system. The CONDUIT system has been proved by large experience to be reliable, provided great attention is paid to its design and construction. It is generally accepted as the only possible alternative to the trolley, but, being costlier and less convenient, it cannot compete upon equal grounds. It has the advantages that it is not unsightly, and affords every facility for an insulated return, which latter is an important point, as it obviates the necessity of bonding the rails, and does away with the usual electrolytic troubles in adjacent pipes consequent upon an earth return. Between the track rails is placed a roomy and well drained conduit, open to the extent of about ¾ in. on top, and built up usually of concrete more or less in the form of fig. 2. Fixed to the walls by the aid of insulators

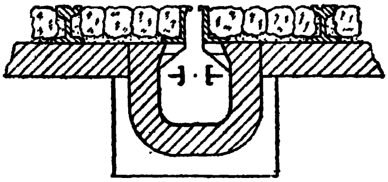

FIG. 2.—SECTION OF LONDON COUNTY COUNCIL CONDUIT BETWEEN YOKES.

are the bare + and − conductors, and between them, passing clear through the slot, runs the collecting plough, picking up the current on the one side by an insulated plate connected to the motors, and returning it by a similar contrivance on the other. In practice, trouble is often experienced in the design and working of crossings and points, and in many cases underground pipes offer a serious hindrance to the construction. The OVERHEAD TROLLEY SYSTEM is, of course, free from such objections, and is consequently very much cheaper to instal and maintain. It derives its name from the fact that originally a small trolley was employed to run on the *top* of the wire, picking up the current, and passing it through a cable to the car; but this was found to be impracticable, and the greatest impetus the overhead system has known resulted from the introduction of the underrunning trolley. In a modified form this is the apparatus used at the present day. Owing to the impracticability of employing two overhead conductors and two trolleys, the current is returned to the power house through the rails, and this calls for the above mentioned necessity of bonding. The Board of Trade regulations with regard to the return circuit are stringent, 7 volts being specified as the maximum allowable drop of pressure over it. In cases where this is exceeded it becomes necessary to instal a negative booster (*q.v.*) in the return circuit of the feeders. Except in special cases where allowance is sometimes made, the Board of Trade rules specify that the speed is not to exceed ten miles an hour, and four miles an hour through facing points; that the overhead conductor is to be electrically split up into sections not exceeding half a mile in length; and that the latter is to be supported, at least every 120 ft., at a height not less than 17 ft. from the ground, except when conveyed under bridges. The electric railway was a natural sequence to the success of the tramway, and is undoubtedly destined to create a revolution in railway operation. Up to the present it has been confined to suburban and short lines, but several important companies have the electrification of their main lines under consideration. In the case of a short line, direct current at a pressure of 500 volts is generated at the power house and fed on to a bare conductor placed adjacent to the track; the return is either through the rails or another special bare conductor. An example of this is the Great Northern and City Railway. The Central London Railway, on the other hand, generates a three phase alternating current at a pressure of 5,000 volts, transforms down in substations, and converts by the aid of rotary converters to direct current at a pressure of 500 volts, and in this form the power is used on the train. There are two distinct methods of electric railway operation in use at the present day, *viz.* the LOCOMOTIVE and the MULTIPLE UNIT system. The former speaks for itself, and its limitations are practically on a par with those of the steam railway; but the second possesses several important advantages. By installing motors at each end and in the middle of the train, the driving power is distributed, which results in increased adhesion to the rails, greater power with reduced local weight, less pounding and vibration, and lighter rolling stock and track. Main lines, owing to their length and the large amount of power consumed, can scarcely be efficiently operated by direct current, except at prohibitive pressures; thus alternating currents must be looked to to solve the problem. Great experimental progress has been recently made in their adaptation to the needs of railway work, and there appears to be but little doubt that the near future will see the realisation of this form of electrical operation upon a large scale. Traction power house plant has of late years received much attention. Experience has proved that the strains set up in the engines and generators owing to the rapidly and sometimes largely varying load are not to be as much feared as was at one time thought to be the case. Good governing and considerable inertia are, however, essential in an engine destined for use on a traction circuit. Where direct current dynamos are used they are always compounded (*see* DYNAMOS), and special attention is paid to sparkless running in their design. A battery is an important adjunct in traction work, as it acts as a buffer, taking up a great deal of the load variation, and therefore saving the engines from abnormal strain. This is specially the case where an automatic reversible booster is used, that interesting piece of machinery having been designed to meet the special requirements of traction work in this direction.

F. H. D.

Electric Waves. When an electrical condenser is discharged by connecting its two coatings together through a conductor, a series of electrical oscillations is set up in the conductor. The plates or coatings become charged alternately with positive and negative electricity. The period of each oscillation is approximately $2\pi\sqrt{LC}$, where L is the coefficient of self induction of the circuit by which the two coatings of the condenser are connected, and C is the capacity of the condenser.

A succession of electrical disturbances or waves will start off from the system through the surrounding medium, having the same frequency as the oscillations in the conducting wire. These waves consist of electric and magnetic disturbances at right angles to each other and to the direction of propagation. The velocity of propagation is given by the equation $v = \frac{1}{\sqrt{K\mu}}$, where K is the SPECIFIC INDUCTIVE CAPACITY (*q.v.*) of the medium through which the waves are travelling, and μ is its MAGNETIC PERMEABILITY (*q.v.*) The waves may be conveniently produced by sparks from the secondary terminals of an induction coil, the conducting wires terminating in two polished spheres or cylinders placed at a small distance apart. To detect the presence of the waves various methods are used. One of the earliest consisted of a metal wire with a polished brass knob at each end, the whole wire bent round into a circular form so that the knobs nearly touch. The area of the circle so formed must be suitably adjusted to the particular wave lengths of the waves it is desired to detect; if this is done, the waves falling on the metallic circuit will produce small sparks which pass between the two knobs. The form of detector which is now most used is known as a COHERER. This consists essentially of loose contacts between pieces of metal. In BRANLY'S COHERER these are metal filings enclosed in a tube, through the ends of which wires are passed to serve as terminals; but many other forms of loose contact will give satisfactory results. A coherer of this type has a very high resistance, but when waves fall on it it becomes a good conductor. On tapping it very lightly after the waves have passed, it returns to its original condition, and ceases to conduct to any appreciable extent. If a coherer be connected in series with a cell and a galvanometer, a deflection of the galvanometer will occur when electric waves fall on the coherer, and will last until the coherer is tapped, when the current ceases, owing to the instant increase of the resistance of the coherer. Using these means for the production and detection of electric waves, many of their properties can be found by experiment. Thus it is found that they are capable of being reflected, refracted, polarised, and made to yield interference effects. Hence electric waves have properties resembling those of light; moreover, it is found that their velocity of propagation is the same as that of light, so far as can be ascertained from experiment. It is now believed, both as the result of theoretical investigations and of experiments, that light waves are simply electric waves of very short wave length and very high frequency; this is the main principle of Maxwell's ELECTROMAGNETIC THEORY OF LIGHT. Of recent years important applications of the properties of electric waves have been made by Lodge, Marconi, and others. *See* WIRELESS TELEGRAPHY.

Electric Welding. In many instances metals can be welded by heating the parts to be joined by electrical means. The process is used for pipes, rods, wires, sheet metal, tanks, barrels, special forms of chemical plant, large objects which cannot easily be moved, and other pieces of work which it would be difficult or even impossible to deal with in the forge. There are two methods, the INCANDESCENCE or THOMSON SYSTEM and the ARC SYSTEM. In the former a very large current with a low voltage (usually one or two volts) is passed across the junction from one piece of metal to the other; intense heat is produced in the immediate neighbourhood of the joint owing to the increase in the resistance of the hot metal. The two pieces of metal, on being pressed together, become welded into a homogeneous mass. Alternating currents are generally used; a small current, at a pressure or voltage of several hundred volts, is converted by a transformer, whose secondary coil may only consist of one single turn, into a large current of low voltage. As the transformer can be placed near the work, the necessity for long leads of sufficient size to carry the large secondary current is avoided; short heavy leads are brought from the secondary terminals of the transformer to clamps fixed on the work itself. The method is very convenient for the welding of large numbers of similar objects, which can be placed in succession in a suitable form of clamp or holder to which the terminals of the secondary circuit are permanently attached. The necessary operations may thus be reduced to a few very simple movements, and skilled labour may be largely or wholly dispensed with. In the Arc System a continuous current of much smaller amount, but with a voltage of 70 to 150 volts, is used, the current being controlled by suitable resistances. The positive terminal is attached to the metal and the negative terminal to a carbon rod, fixed in a holder which is held by the operator, or, in certain cases, is moved by mechanism. A powerful arc is formed between the metal and the carbon rod, and is caused to travel along the joint. By this method large pieces of work can be welded up *in situ*; but the operator requires a considerably higher degree of skill than is necessary in the case of the first method.

Electrification. The condition of a body which has received a charge of electricity. *See* ELECTRIC CHARGE *and* ELECTRICITY.

Electrochemical Equivalent. The mass (in grams) of a substance deposited by the passage of unit quantity of electricity (one coulomb). The electrochemical equivalent of hydrogen is ·000010352; that of any other element is obtained by multiplying this number by the chemical equivalent of the element in question.

Electrode. A conductor by which electricity enters or leaves any piece of apparatus; especially the two conductors (ANODE and CATHODE) by which a current enters and leaves an electrolyte.

Electrodynamometer. *See* DYNAMOMETERS, ELECTRICAL.

Electrolysis. *See* ELECTROLYTE.

Electrolyte (*Elect.*) A liquid with the property of conducting electricity by means of ELECTROLYSIS, or the splitting up of its molecules (or of the molecules of a substance dissolved in it) into separate atoms or groups of atoms, termed IONS. The ions themselves carry charges of electricity, and travel with a small but definite velocity through the liquid.

Electrolytic Dissociation. *See* DISSOCIATION.

Electromagnet. A core of iron or steel round which is wound a coil or SOLENOID of insulated wire, through which a current can be passed. The iron becomes magnetised during the passage of the current; when the current ceases, the magnetisation falls off to a very great extent, and may vanish almost entirely in the case of very soft iron.

Electromagnetic Theory of Light. *See* ELECTRIC WAVES.

Electrometallurgy. Metallurgical processes which are carried on either by the heat of the electric furnace (*q.v.*) or by the chemical action of an electric current. The preparation of pure copper by electrodeposition from a solution of impure copper salts is a good example of the latter method. Much of the copper employed for electrical purposes is now prepared in this manner. *See* COPPER.

Electrometer. A piece of apparatus for measuring differences of electrical potential. The simplest form is some modification of the electroscope (*q.v.*) provided with a scale for finding the angle of divergence of the gold leaves. The instrument has to be calibrated by the observation of the divergence produced by known differences of potential. The ATTRACTED DISC ELECTROMETER depends upon the mechanical force between two metal discs, which are charged up to the two potentials whose difference it is required to measure. If the distance between the plates is kept constant, the force with which they are attracted is proportional to the square of the difference of potential. If the distance between the discs is varied, the attracting force being kept constant, the difference of potential is simply proportional to the distance between the plates. The QUADRANT ELECTROMETER consists of a light paddle-shaped needle C, usually made of aluminium. This is suspended by means of a controlling fibre D, so that it can turn inside two pairs of hollow metal quadrants, AA, BB. In its position of rest it lies symmetrically between the two pairs, as shown. To measure a small difference of potential $V_1 - V_2$ (*e.g.* the difference of potential between the terminals of a single cell) the two quadrants AA are connected to one terminal of the cell and charged to the potential V_1; the pair BB are similarly connected to the other terminal, and charged to the potential V_2. The needle is maintained at a very high potential V_3 by connecting it to the inside coating of a small charged Leyden jar placed underneath the quadrants. Then, if the couple required to turn the needle through a given angle be proportional to this angle, the observed deflection will be proportional to $(V_1 - V_2)V_3$. Thus, if V_3 be kept constant, we can compare various values of $V_1 - V_2$, and the absolute value of this quantity can be found by observing the deflection produced by a Clark cell. To measure large differences of potential the needle is connected to one pair of quadrants; the couple exerted on the needle (and consequently the deflection) is then proportional to $(V_1 - V_2)^2$, where V_1 is the potential of one pair of quadrants, and V_2 is that of the needle and remaining pair of quadrants.

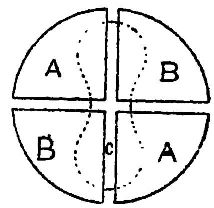

FIG. 1.—ELECTROMETER.

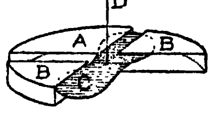

FIG. 2.—ELECTROMETER.

Electromobile. An electric automobile or motor car. *See* ELECTRIC AUTOMOBILE.

Electromotive Force *or* **E.M.F.** That which tends to cause the motion or flow of electricity. It is frequently termed ELECTRIC PRESSURE, or merely PRESSURE, by electrical engineers.

Electron. The name now generally used to denote the very small negatively charged "corpuscles" which constitute the cathode stream in high vacua, and which are also produced under other circumstances; *e.g.* they are emitted from negatively charged surfaces exposed to ultra-violet light, and also form the β rays emitted by radium. The negative charge carried by each electron is about $3{\cdot}4 \times 10^{-10}$ absolute electrostatic units, and appears to be a natural unit of quantity or a kind of "atom" of electricity. The mass of an electron is about $\frac{1}{700}$ to $\frac{1}{1000}$ of that of a hydrogen atom; but it is as yet uncertain whether this mass is real or of purely electrical origin, due to the fact that a charge in motion behaves as if it possessed inertia. *See also* ELECTRICITY.

Electrophorus. A flat plate of resin, or ebonite, laid on one conducting plate, and covered with another, which can be raised by an insulating handle. A small charge imparted to the resin (by rubbing) can be made to induce successive charges on the upper plate, which may be utilised in any way required. The source of energy is the separation (by the operator) of the plate and cover, which carry charges of opposite sign, causing an attractive force to be exerted between them. The work done in separating these charges appears as increased electrical energy on the upper plate, as its potential is raised by its withdrawal from the vicinity of the resin.

Electroplating. In general terms this consists of depositing the precious metals on the base metals (or on non-metallic substances which have been coated with a conductor) by means of electrolysis (*q.v.*) The articles to be electroplated form the cathode pole (*q.v.*) in a solution of the precious metal, the anode or + pole usually being a plate of the metal to be deposited. When a current of electricity is passed through the solution, a thin coating of metal is deposited on the articles forming the cathode, and the decomposed ions (*q.v.*) take up a fresh supply of metal from the anode. The individual methods of electroplating in general use are: (1) nickel plating, extensively used for making German silver goods and plating harness makers' ironmongery, buckles, etc.; (2) copper plating, generally employed for facing printing blocks, and coating non-metallic substances prior to gold, silver, or nickel plating; (3) silver plating, for cutlery and imitation silver ware; (4) gold plating, for ornamental work, and to a limited extent in the chemical industry, for lining the apparatus in which highly corrosive acids are rectified; (5) "Brassing" or conjoint deposition of zinc and copper in the proportions which constitute that alloy of these metals, called brass. Deposits of several other metals are obtainable, including aluminium, cadmium, antimony, bismuth, cobalt, iron, lead, and magnesium; and the principle of electro-deposition is employed for the separation of certain metals in the analysis of complex ores. The *process* of *plating* may be divided into two sections: the cleansing of the goods to be plated, and the preparation and management of the plating BATH, as the solution of the metal to be deposited is known technically. Cleansing consists in removing all grease, dirt, and scale, or oxide, by means of caustic alkali solution or acid pickle. The latter must not be used for lead, tin, or pewter. Iron is usually pickled in a solution of vitriol. For brass, DIPPING acid is often employed, being a mixture of nitric acid (aquafortis) and vitriol. In this way the goods are BRIGHTENED immediately before plating. In some cases it is necessary to prepare the goods by SOFTENING, which is really amalgamating slightly with

mercury; a cyanide scour is also employed sometimes, the object in all cases being to ensure the more perfect adhesion of the metallic deposit. For steel a muriatic acid pickle is usually employed. In the cleansing process, scratch-brushing is often used to produce a smooth surface, assisted by scouring with pumicestone. The quality of the plating largely depends on the way the surface is prepared, and cleansed, the articles being immersed in the bath immediately after cleansing and dipping. If a matt surface or dead lustre is desired, the goods, after cleansing and scratch-brushing, must be specially dipped, before plating, in a bath of aqua-fortis, vitriol, and a little white vitriol (zinc sulphate) and common salt. As this method is most applicable to copper or its alloys, other metals should be copper plated, and then prepared for a matt surface as just indicated. (6) The "bath" when made may be worked either hot or cold. Its composition depends on the articles to be plated, the current employed, and several minor factors which are determined by the individual working conditions. There are generally two brass rails round the top of the trough containing the plating bath, connected severally with the + and − poles of the battery or dynamo, and insulated from each other. By laying rods carrying the anodes on one rail and the cathodes on the other, the disposition of the articles in the bath (relative to the anodes, depth of immersion, etc.) can be adjusted so as to obtain the best deposit. *Nickel Plating* is one of the simplest and easiest managed methods of plating. There are about sixteen methods of preparing the "bath," which is usually worked hot; *i.e.* about 100° F. But in almost all cases the double sulphate (or chloride) of nickel and ammonium is the basis. Salt, sal-ammoniac, benzoic acid, etc., may be added, and are considered advantageous by various operators. Cast nickel plates are used for anodes, and care must be taken that by no chance shall the goods to be plated come in contact with the anodes. The current should be carefully regulated, as if too strong the deposit will be dull or "burnt," and if too weak, granular. The latter is a serious objection, as the nickel deposit will not stand the action of a burnisher, being of a brittle nature. For the same reason the surface must be carefully prepared before plating, to ensure the deposit being of the desired nature. *Copper Plating:* The bath is usually an acid solution of the sulphate or acetate of copper, containing also cyanide of potassium. For zincs and certain other articles an alkaline bath is used. Either hot or cold baths are used, the temperature for the former being 110° to 130° F. For iron, plain dipping without the passage of a current is sometimes adopted. The anodes are plates of copper presenting a surface at least equal to that of the goods to be plated. The hot bath is more rapid than the cold, and is specially suited for articles which are difficult to clean. Small articles should be kept agitated in a ladle or "trussed" on a wire. *Silver Plating:* The double cyanide of silver and potassium is used for the bath, prepared by dissolving nitrate of silver and cyanide of potash in water. Cold baths are mostly used for large articles and heavy deposits, and hot baths for small articles, and especially for tin, lead, zinc, iron, or steel goods, with a fairly strong current if constant agitation is adopted. For the best electroplate a preliminary amalgamating dip or else a "whitening" bath is almost always practised (*vide supra*). The bath improves, with working, and if portions of an old bath cannot be utilised in making up a fresh one, a bluish yellow deposit may be anticipated till the bath has aged a little. Silver foil or plate is used for the anode, which should have a greyish appearance when the current is passing. If black, there is not enough cyanide present; if white, there is too much, and silver cyanide must be added until a grey anode is obtained. Too strong a current produces a black deposit; a weak current yields a fine and dense deposit. A weak current and lengthened immersion produce a coating which burnishes far better than that from a strong current and quick plating. *Gold Plating:* A hot bath is customary at about 170° F., the cold method only being used for very large objects, such as chandeliers, but it needs much care and attention. The double cyanide of gold and potassium is used for all baths. The anode is generally platinum foil. Gold baths require considerable variation in composition for different metals. A universal bath is seldom a success. Excess of cyanide causes very slow plating, and the colour of the deposit ranges from green to red, according to the strength of the bath. This factor is also controlled by regulating the area of platinum anode exposed in the bath in a way which would be impossible with gold anodes. The greater the surface of platinum anode in the bath the redder the deposit. Gold plating is often applied only to selected portions of an article. To effect this a stopping-out varnish is used on the parts to be protected. *Brassing:* There are numerous methods of preparing baths, some eighteen recognised formulæ being practicable. Cyanides of zinc and copper, in conjunction with liquid ammonia or bisulphites, form the foundation of the majority, arsenious acid being used occasionally to brighten the coating, but only minute quantities are permissible, if deemed desirable. The chief difficulty is maintaining a deposit of uniform colour. A deficiency of current increases the copper, giving a red brass, and an excess brings up the zinc, resulting in a blue or pale brass. The amount of cyanide is also important. The anodes are brass plates, and all the articles must be kept at equal distances from them when plating. Hot baths are usual at about 135° F. (except for lead at 90° F.) Agitation is generally to be avoided. After all kinds of plating, the goods are rinsed in water, washed in boiling water (and in the case of brass goods in lime water), placed in sawdust, and sometimes stove dried. They are then burnished (if permissible) and buff polished. Anodes should always be removed from the bath when not plating, and the current should be started as soon as the articles are immersed, to avoid standing in the bath before plating. DIRECT COLD PLATING or FRICTION PLATING solutions have been introduced quite recently which contain *no cyanide* or other *poisonous* ingredient. They are essentially composed of very finely divided, precipitated chloride of silver, in the presence of excess of common salt, mixed with an abrasive, such as emery, rouge, or putty powder. By rubbing the solution on to copper, brass, bronze, etc., with a piece of clean flannel or cloth, a thin coating of pure silver is deposited. They do not lend themselves well to rough or ornamental surfaces.

Electroscope. An instrument for detecting small charges of electricity. The usual form consists of two pieces of gold leaf suspended from a conducting rod, so as to touch each other throughout their whole length when at rest. On connecting the conductor of the instrument to a charged body, the leaves become charged, and repel one another. A better form consists of a single narrow strip of gold leaf

which when at rest hangs vertically, in contact with an upright rod, to which it is attached at its upper end. The portion of the rod carrying the gold leaf or leaves is enclosed either in a glass case or in a wood or metal case provided with glass windows, through which the divergence of the leaves can be observed. The rod must be carried on a support which insulates it from contact with the case; the latter is connected to earth.

Electrotype Plates (*Print.*) A replica of type, woodcuts, etc., forming a printing surface. Produced by a galvanic deposit of copper which is afterwards backed up with an alloy.

Electrum (*Met.*) (1) An alloy of gold and silver, of the colour of amber, used by the ancient Greeks and Romans. (2) An alloy of copper, zinc, and nickel. (3) Native argentiferous gold, containing a large percentage of silver.

Element (*Chem.*) A substance which the chemist cannot, by any of the means under his control, resolve into two or more simpler substances. Among the best tests of the elementary nature of a substance are: (1) The effect of heat; the substance should not be decomposed. (2) The effect of an electric current; it should not undergo electrolysis. (3) Its spectrum; it should not contain a line or band exhibited by any other substance. (4) It should have, as a rule, a definite position in the periodic system. (5) Its behaviour on treatment with other substances, such, for example, as carbon, oxygen, chlorine, etc.

Elements (*Meteorol.*) The different items by which the total meteorological condition of the atmosphere is represented. These are: temperature, pressure, humidity, precipitation, evaporation, wind, cloud, electrical and optical conditions of the air.

Elements of an Orbit (*Astron.*) Quantities, seven in number, which describe an orbit of a planet accurately, and from which the planet's place can be found at any given time, past, present, or future, so far as the attraction of the sun alone is concerned.

Elemi (*Botany*). *Canarium commune* (order *Burseraceæ*). A resinous substance used in pharmacy. MANILA ELEMI is said to be the exudation from the stem of the above plant, while AMERICAN ELEMI is obtained from *Bursera gummifera.*

Elephant (*Print.*) A size of paper measuring 30 by 23 inches in printing, and 28 by 23 inches in writing and drawing papers.

Elers (*Pot.*) Elers ware was first made at Bradwell, Staffs, by John Philip Elers, about 1690. The ware is a red pottery of fine texture and careful execution. Elers was the first to introduce salt glazing into England. This is done by throwing salt into the fires when the kiln is at its hottest. The fumes given off combine chemically with the surface of the ware, causing a glaze to form upon it.

Elevation (*Eng., Build., etc.*) A view of an object as seen by an observer standing in front of the particular side represented. Thus FRONT ELEVATIONS are views of the front of a building; END ELEVATIONS are views of the end, etc.

Elevation Craters (*Geol.*) Most volcanoes occur within areas undergoing upheaval. The older geologists, noting this fact, were led to regard the conical form of volcanoes in general as having been due to local elevations caused by subterranean movements. Volcanic cones are now regarded as having been built up by the long-continued accumulation of lava streams and beds of tuff.

Elevators (*Eng.*) A series of buckets attached to an endless belt or chain for raising solids, etc., from one level to another up an inclined plane. The ascending buckets pass through a "boot" or hopper in which they scoop up a charge of material and discharge their contents as they begin to descend; *e.g.* dredger buckets.

Elgin Marbles (*Sculp.*) The most notable and valuable collection of ancient Grecian sculptures extant. They were brought from Greece by the seventh Earl of Elgin, and were purchased from him for the British Museum in 1816 These sculptures formed part of the adornments on the buildings of the Acropolis, Athens, and include many designs by Pheidias from the Parthenon or Temple of Athena.

PORTION OF THE FRIEZE OF THE PARTHENON.

The most important of these are the figures of Theseus or Hercules, Ilissus, and one of the horses of Night; fifteen Metopes in high relief, representing the battle of the Centaurs and Lapithæ; and a large portion of the exquisite frieze on the outer walls of the Cella, representing the procession to the Parthenon during the Panathenaic festival.

Elizabethan Architecture. *See* RENAISSANCE ARCHITECTURE.

Ellagic Acid (*Chem.*), $C_{14}H_8O_9$. A compound produced by the oxidation of gallic acid. It occurs in the oak bark, together with gallic acid and tannin; it separates out during the processes of tanning. *See* BLOOM.

Elland Stone. *See* BUILDING STONES.

Ellipse. A curve symmetrical about two axes at right angles, and such that if P be any point on the curve, and A, B, two points on the longer or MAJOR AXIS, which are termed the FOCI, then AP + BP is constant. The curve may be obtained by cutting right across a cone, at an angle with the base.

Ellipsoid. A solid whose three principal sections, taken at right angles to each other, are ellipses.

Elliptical Arch (*Build.*) An arch having the curve of a semi-ellipse.

Elliptic Comets (*Astron.*) The paths of comets are either elliptic, parabolic, or hyperbolic; there are about eighty-five (in 1902) which travel in elliptic orbits, and are called by the above name.

Elliptic Trammel. A device for drawing ellipses. A straight rod carries a pencil and two studs projecting at right angles to itself. The studs slide in two straight slots at right angles to one another. Each stud travels along one slot, *i.e.* in a straight line, and the pencil then describes an ellipse.

Elm. *See* WOODS.

Elongated (*Typog.*) A style of type of increased height in proportion to the normal width.

Elongation (*Astron.*) The difference between the celestial longitude (*q.v.*) of a body and the celestial longitude of the sun.

Elution (*Chem. Eng.*) A process for recovering sugar from molasses.

Elutriation (*Chem., etc.*) The separation of a lighter from a heavier powder by washing away the lighter one.

Elvan (*Geol.*) A name used by the Cornish miners, as well as by many geologists, for the dykes or wall-like masses of intrusive rocks allied in composition to granite, which rise through the older rocks of Cornwall and Devonshire, mostly in the neighbourhood of the large granite masses of those parts. Most elvans are, lithologically, quartz porphyries, but a few are more of the nature of porphyrites (*q.v.*)

Elzevir. The name applied to books printed by the Elzevier (Lat. *Elzevirius*) family at Amsterdam, The Hague, Leyden, Utrecht (1592—1680). The most valued are their editions of the classics, which are notable for their accuracy and for the elegance and neatness of the type.

Embankments (*Civil Eng.*) Masses of earth (obtained in excavation) raised above the level of the surrounding land: they serve to carry roads and railways, and as sea walls, river walls, etc.

Embattled (*Architect.*) Having battlements. One of the enriched mouldings used by the Normans is known as the embattled moulding, as it is carved to represent BATTLEMENTS (*q.v.*)

—— (*Her.*) One of the dividing lines of a shield, in form like the battlements of a castle. The angles are right angles.

Embedded Conductors (*Elect. Eng.*) Conductors on an armature of a dynamo or motor which run through grooves or channels in the iron core.

Embolite (*Min.*) Silver chlorobromide, Ag(ClBr); cubic; colour, asparagus green. It occurs in Chili in some quantity, also in Mexico and in Honduras.

Embossing. Ornament executed in relief, generally on a wrought surface. Applied also to carving or moulding done in relief.

—— (*Leather Manufac.*) Printing or embossing certain grain marks on skins by means of hot plates or rollers.

Embouchure. (1) The mouthpiece of wind instruments. (2) The position of the lip, etc., of performers on wind instruments.

Embowed *or* **Flected** (*Her.*) Curved or bent. It is employed for charges, as a fesse "embowed" instead of straight; or of some parts of the human body, such as the arm, and it is the position in which a fish is generally depicted.

Embrasure (*Architect.*) An opening in an embattled parapet. *See* BATTLEMENT.

Embroidery (*Lace Manufac., etc.*) Ornament on a fabric of any description, done either by hand with a needle, by the aid of a sewing machine, or by means of the embroidery machine. The foundation or fabric that is embroidered may be of such character as to be considered part of the scheme or design; or it may serve merely as a base until the work is completed, *e.g.* 'BURNT OUT' LACE (*q.v*). *See also* BAYEUX TAPESTRY.

Emerald (*Min.*) This well known bright green gem is a variety of beryl (*q.v.*) It is found in Siberia, Hindustan, Brazil, Norway, in the Andes, etc.

——, **Brazilian** (*Min.*) A green transparent variety of Tourmaline (*q.v.*)

Emerald Copper (*Min.*) A synonym for Dioptase (*q.v.*)

Emerald Green (*Dec.*) The brightest pigmentary green. Its hue is almost identical with spectrum green. *See* COLOURS (PIGMENTS, *etc.*) It contains a large proportion of arsenious oxide, and, being poisonous, its use has declined in recent years. It cannot be mixed with pigments containing sulphur, such as ultramarine, cadmium yellow, etc. In the United States it is called PARIS GREEN, and is largely used there as an insecticide.

Emerald Nickel (*Min.*) A hydrous carbonate of nickel, $NiCO_3 \cdot 6H_2O$. Oxide of nickel = 59·4, carbonic acid = 11·7, water = 28·9 per cent. Colour, emerald green. It occurs as an incrustation on decomposing nickel ores. Shetland, and Texas and Pennsylvania in the United States. Also called ZARATITE.

Emery. The rough massive varieties of CORUNDUM (*q.v.*); much used as an abrading agent. The emery of commerce often contains microscopic crystals of sapphire. Powder of varying degrees of fineness is obtained by crushing the mineral. It is used in the form of powder for grinding hard surfaces, or is formed into solid hones or into small wheels for sharpening tools of hard steel (such as twist drills, etc.) Found in Asia Minor, the Urals, and the United States. *See also* CARBORUNDUM.

Emery Buff (*Eng.*) *See* EMERY WHEEL.

Emery Paper and Cloth (*Eng., etc.*) Powdered emery attached to paper or cloth by glue; used for finishing metal surfaces.

Emery Wheel (*Eng.*) A wheel consisting of powdered emery made up into a solid mass with some kind of cement; used for grinding metal surfaces and sharpening tools. Wheels made of the finest emery are used for polishing; these are termed EMERY BUFFS.

Emission *or* **Corpuscular Theory of Light** (*Phys.*) An early theory that light was due to a great number of very minute particles or corpuscles projected or radiated from luminous bodies or sources of light. It is now superseded by the Wave Theory (*q.v.*), of which the Electromagnetic Theory is a development.

Emperor (*Print.*) A size of writing or drawing paper measuring 72 by 48 inches.

Empirical Formula (*Chem.*) *See* CHEMICAL FORMULÆ.

—— *or* **Rule.** A formula or rule which is based on the result of trial or experiment, not on theoretical calculations. A very large number of the rules used in various trades are of this nature.

Empress (*Build.*) A roofing slate measuring 26 by 16 inches.

Em Quads (*Typog.*) Quadrats or metal spaces used for filling out short lines, and cast 1 em (m) square to any particular body.

Em Rules (*Typog.*) Rules cast on an em (m) of any particular body, such as an em dash, —.

Emulsin (*Chem.*) An enzyme (*q.v.*) It occurs in almonds and probably in all plants which contain an enzyme capable of hydrolysing glucosides. It

can be obtained as a white powder by rubbing pressed almonds to a pulp with water, allowing to stand till acid fermentation sets in, filtering and precipitating with alcohol. It has the property of hydrolysing a large number of glucosides (*q.v.*); *e.g.* amygdalin, salicin, arbutin, etc., and it is remarkable that it hydrolyses milk sugar. *See* AMYGDALIN.

Emulsion (*Photo.*) A sensitive salt of silver held in suspension (in a very fine state of division) in collodion or gelatine.

Emys (*Zoology*). A genus of pond tortoises found in South Europe and in North America. They are eaten by the natives of the countries in which they live.

Enamel. The manufacture of enamel reaches back to prehistoric times, examples having been discovered in this country dating back to the Iron Age, while the Babylonians have left many specimens on their enamelled bricks. Enamels generally consist of a vitreous base, rendered more or less opaque by the addition of cryolite (*q.v.*) or fluorspar, colour being obtained as a rule by the addition of various metallic oxides. Enamels are usually applied either to pottery or metals; in both cases the enamel is caused to adhere by fusion. CHAMPLEVÉ ENAMELLING: The design is drawn on a copper plate, all the parts to be enamelled being excavated and the hollows filled in with enamels, which are fused and the surface then ground smooth. Limoges, in France, was for centuries the chief centre for this kind of enamelling. CLOISONNÉ ENAMELLING: The design is outlined by means of metal strips fixed on edge to the surface to be treated; the spaces between the strips are filled in with enamel, which is then fused and ground smooth, as in the preceding case. Examples of this kind of enamel are to be found in early Byzantine work. TRANSPARENT AND TRANSLUCENT ENAMELS were used by the Italian goldsmiths in the thirteenth century. ENAMEL PAINTING: This art, practised largely in the sixteenth century, is now rarely employed except for utilitarian purposes, such as names of streets, notices, advertisements, etc.

—— (*Cycle*). The "body" of the enamel is some resin, amber, or asphalt. This is dissolved in a solvent consisting of turpentine and boiled oil. Each coat is hardened by heating in an oven before the next is applied.

—— (*Dec.*) Paints drying with a highly glossy surface, made in a large variety of colours by mixing a pigment such as zinc oxide with copal varnish and other thinners (*q.v.*) The use of this class of paints has increased considerably of late years, both for inside and outside work. *See* ENAMELLING.

—— (*Glass Manufac.*) Coloured glass in which an excess of colouring agents are present, causing opacity.

—— (*Pot.*) Enamel colours are those containing soft fluxes that will melt and become affixed to the glazed ware in the enamel kiln (*q.v.*)

—— (*Zoology*). The substance forming the covering to the teeth. It is very hard, and has but little organic matter in its composition.

Enamel Kiln (*Pot.*) This differs in construction from the bisque and glost ovens, being of the MUFFLE form; that is to say, the flues encircle the inner lining of the kiln, and the heat is communicated to the ware by radiation, not by contact. It is used for firing painted and gilt wares. *See also* POTTERY AND PORCELAIN.

Enamelled Leather (*Leather Manufac.*) Known as PATENT LEATHER. The leather is coated with a varnish, and then heated. The varnish may be made any colour with metallic pigments. This gives the leather a coating similar to enamel.

Enamelling (*Dec.*) The process of painting wood and other work with an enamel giving a very glossy surface. In the best work at least six undercoats are given before the enamel is applied, and each is carefully rubbed down with fine sandpaper before the next is applied. In common work enamels are sometimes applied directly upon the ground, but this results in making the inequalities conspicuous.

—— (*Eng., etc.*) The coating of metal with some form of varnish, usually of a bituminous character. In many cases this is fused or STOVED by raising the whole piece of work to a high temperature.

—— (*Photo.*) The process of imparting a glossy and brilliant surface to a print by coating it with collodion or some other transparent medium, to which a smooth surface can be given; the term is sometimes applied to the mere burnishing of the film by steel rollers, etc.

Enantiomorphism (*Chem.*) Two crystals are said to be enantiomorphous when they are composed of the same crystallographic elements (faces, edges, angles), so arranged that the one is the mirror image of the other; that is, the one crystal cannot by any process of changing its position or by rotating it in any way be brought to congruence with the other. The right and left hands are enantiomorphous. Crystals of optically active substances are enantiomorphous, one crystal corresponding to the dextro compound and the other to the lævo compound.

Encastré (*Eng.*) A beam whose end or ends are built into a wall is said to be Encastré.

Encaustic. *See* PAINTING (METHODS).

Encaustic Painting. *See* PAINTING (METHODS).

Encaustic Tile (*Build.*) A coloured, baked, and glazed tile.

End (*Textile Manufac.*) A warp thread.

Endellionite (*Min.*) A synonym for BOURNONITE (*q.v.*)

Endemic (*Hygiene*). This term indicates a disease affecting a number of persons in a particular district, the cause being largely due to local circumstances. Of examples we have cholera in certain parts of India and smallpox in the Soudan.

End Grain. The surface of timber which is at right angles to the direction of the grain—*i.e.* a cut across the log or plank.

Endless Paper (*Print.*) Paper used in rotary machines, supplied in reels, as distinguished from paper in sheets.

Endless Rope *or* **Chain** (*Eng.*) A common expression for a chain or rope with its ends joined together; often used for transmitting power, as in a cycle or an overhead crane.

End Links (*Eng.*) Links of slightly greater strength than the ordinary links of a chain; added at the ends for welding up when the chain has to be connected to any other object. *See also* SHUTTING LINKS.

End Measurement (*Phys., Eng., etc.*) A measurement of length made by means of contact with the extreme end of the object. Callipers, screw gauges, and the Whitworth measuring machine all give end measurements.

Endocarp (*Botany*). The STONE or innermost layer of the pericarp of a drupe (*q.v.*) The shells of the walnut, cocoanut, and almond are the endocarps of drupes.

Endosperm (*Botany*). The tissue containing food substances (starch, proteid, oil, or cellulose) in certain seeds. *See* ALBUMEN.

Endothelium (*Zoology*). A form of squamous epithelium lining the body cavity and blood vessels.

Endothermic Compounds (*Chem.*) Compounds formed from their elements with absorption of heat. Most endothermic compounds cannot be formed *directly* from their elements; in such cases the heat of formation is obtained by calculation. Hydriodic acid, carbon disulphide, acetylene, the oxides of nitrogen (N_2O and NO) are examples of endothermic compounds.

End Papers (*Binding*). Usually known to the public as FLY LEAVES. The white or coloured sheets placed by the binder at the beginning and end of a volume, one half being pasted down upon the inside of the cover.

Endromis (*Archæol.*) A thick warm wrap, used principally by Greek and Roman athletes to prevent them from taking cold after exercise. There are frequent representations in classical art.

Energy (*Phys.*) The power or capacity for doing work. *See* KINETIC, POTENTIAL, RADIANT ENERGY, *etc.*

Engaged Column (*Architect.*) A column attached to a wall and projecting not less than half its diameter from the wall face.

Engine. (1) In the older uses of the word, any piece of mechanism. (2) A piece of mechanism used to convert heat or some other form of energy into mechanical work; in other words, a machine for the development of POWER (*q.v.*) from some source of energy, such as coal, gas, oil, compressed air, etc. *See* STEAM ENGINE, GAS ENGINE, *etc.*

Engine Cylinder, *etc.* (*Eng.*) *See* STEAM ENGINE, GAS ENGINE, *etc.*

Engine Friction (*Eng.*) The FRICTION (*q.v.*) between the moving parts of an engine; it is one of the chief causes of loss of power in the engine itself.

Engine Pit (*Eng.*) A depression or pit into which a man can get to examine the lower parts of a locomotive, motor car, etc., which is placed over the pit.

Engine Register (*Eng.*) A counting mechanism for showing the total number of revolutions made by an engine in any given time.

Engine Sized Papers (*Paper Manufac.*) Papers sized by the addition of resin, size, or other sizing materials, in the beating engine.

Englanté (*Her.*) *See* FRUCTED.

English Bond (*Build.*) A wall showing alternate courses of HEADERS and STRETCHERS (*q.v.*) on the face.

English Degrees. *See* DESCROIZILLES.

Engobe (*Pot.*) A term applied to a white paste or pipeclay found on ancient pottery.

Engrailed (*Her.*) A divisional line formed of semicircular indentations with the points from the figure. *See under* HERALDRY.

Engraving *and* Etching. The term engraving is necessarily comprehensive, since one may engrave upon almost any material—metal, wood, glass, shells, and even the soft plaster of the gable of a house, which latter process, called sgraffito, is really a kind of engraving. For the various methods of engraving upon metal plates, steel, copper, and zinc are most commonly used; the latter, however, only for coarse kinds of work, zinc being a very soft and porous metal. The processes employed in engraving and etching are intimately associated, and may be said to overlap each other, since most engravers make use of an etched line as a foundation for subsequent work with the burin, or graver, while on the other hand many etchers employ the burin as an adjunct or auxiliary to their etched work. The chief difference between the two processes is that while engraving implies the cutting or gouging of lines or spots by means of a sharp instrument, etching consists of biting or eating into the plate by means of acid or other chemicals. The result in each instance is essentially the same, a series of lines or other disturbance of the smooth surface of the plate, making an *intaglio* capable of holding printer's ink, from which a proof may be taken by pressure. LINE ENGRAVING: Line engraving does not appear to have been practised as a fine art before the beginning of the fifteenth century. It was largely employed for the illustration and embellishment of the earlier printed books, both in Germany and Italy, and afterwards as a means of reproducing pictures and other works of art. At the present time the art of pure line engraving is almost extinct, mainly owing to the length of time necessary to complete a plate, an important engraving on a steel plate not unusually occupying five years or even longer. The line produced is clean cut, even, and necessarily, from the method employed, somewhat severe, in this respect contrasting with the greater freedom of the etched line. *Printing of Line Engravings:* After being inked, the surface of the plate is wiped clean, the ink being left in the lines. The process employed in the printing of etchings, called "retroussage," is not employed. The impression struck off on paper is called an "Engraving." MEZZOTINT: This is a process by which the ground of the plate is entirely broken up by means of an instrument called the rocker or cradle. It raises a burr in such quantity as to give a rich full black in the proof. The plate is rocked from all possible angles—an extremely tedious process, forty different ways making a full ground. The ground is lowered for lighter tones by means of scrapers, the highest lights being polished with the burnisher. The ground is left untouched for the darkest shades. Pure mezzotints are produced entirely by means of the rocked ground and scraping. It is, however, a common practice to etch the outline of the subject first, and afterwards to have the ground rocked. The prints of Turner's famous "Liber Studiorum" were executed in this manner. Turner himself etched the outline or skeleton with a strongly bitten line, and trained engravers to carry out the mezzotinting. Mezzotint engraving was invented by Ludwig von Siegen, an officer in the service of William VI., Landgrave of Hesse-Cassel. Von Siegen communicated his secret to Prince Rupert, who introduced the art into England, and executed a number of plates, the most famous of which is "The Great Executioner," after Spagnoletto (1658). The golden period of mezzotint was between 1770 and 1800, when the principal paintings of Reynolds, Romney, Hoppner, and other artists were engraved in the most superb manner. These prints command a large price at the present time. STIPPLE ENGRAVING: This process is an

elaborate system of dots, no lines being used. The dots are arranged in such manner as to express the planes and modelling of the subject. In this process etching is employed as an adjunct or rather as a foundation for subsequent work with the burin, the dots being etched on a ground by means of an acid, and afterwards added to and deepened with the burin. The point of the stipple graver is bent *downwards*, this being the best shape for picking into the dots. For line engraving the burin is curved *upwards* at the point. Both bitten and cut lines are occasionally used in conjunction with the dots. Stipple engraving was introduced into this country by William Wynne Ryland (1738—1783). He acquired the art in France, where it had just been perfected by Jean François. Bartolozzi was one of the most successful practitioners of this method. Both mezzotint and stipple engravings were frequently printed in colours. WOOD ENGRAVING: The chief difference between metal and wood engraving lies in the fact that while in metal engraving the lines are represented by grooves cut in the metal, in wood engraving *the spaces between the lines are cut away*, leaving the lines in relief. This necessitates a very different method of printing, since in the case of metal the lines or grooves are filled in with printer's ink, and the surface of the plate wiped clean; whereas on wood it is the *surface only* of the block, represented by the lines in relief, which is inked. The tool employed is the graver, used in the same way as for metal. The earlier wood engravers made use of a small knife. Flat "scaupers" are used for clearing away spaces between the lines. The wood is usually box, although maple, plane, apple, pear, and beech are occasionally used for various kinds of work. The art of wood engraving originally came from the East, where it was practised by the Chinese from a very early period. Different forms of wood engraving have, however, been practised at most periods of the world's history, wood stamps being extensively employed by the Egyptians and Romans for the stamping of bricks and other materials; and wood blocks were also used, and are still used, for the stamping of printed fabrics—in fact, this is the process which William Morris employed at his works at Merton Abbey. Broadly speaking, the practice of wood-engraving as a fine art is coeval with the invention of printing, and from the earlier part of the fifteenth century onward most printed books were embellished with wood cuts, some of which attained a very high degree of excellence. Wood-engraving perhaps touched its high water mark in the hands of Dürer and Hans Burgkmair. From the beginning of the seventeenth century the art gradually declined; but the end of the eighteenth century was destined to witness a remarkable revival at the hands of Thomas Bewick, Blake, and others. Cheap modern "processes" have now almost completely superseded wood-engraving as a means of reproduction; but within the past few years there has been a distinct revival of this means of original expression, and an effort is being made to recall the best principles of the art. The late William Morris would have nothing whatever to do with "process," and all the illustrations of the famous Kelmscott Press were engraved, not indeed by the artists themselves (although Morris executed several blocks with his own hand), but by a capable artist who was perfectly in sympathy with the great traditions of the art. Original wood engraving is now being practised by a number of artists of distinction. In France it is the chief means of expression of one of the greatest of living craftsmen, M. Lepere.

ETCHING.

The meaning of the word etching is to eat or bite in, such biting being accomplished by means of some corrosive acid. A metal plate (usually copper) is covered with a "ground" formed of a thin coating of wax, capable of resisting the action of the acid. The subject is drawn upon the ground with a needle point, just sufficient pressure being used to remove the ground and lay bare the metal. The plate is then immersed in a bath of acid, which attacks only the lines drawn upon the plate. Lines of varying thickness are obtained by regulating the duration of the immersion. The fine lines are stopped out by means of a varnish applied to these lines, the stronger lines being obtained by again immersing the plate. The back and edges of the plate are also protected from the acid by means of such varnish. The printing of an etching requires considerable skill, very different results being obtained from the same plate in different hands. The plate is first heated, and the lines are filled in by means of a dabber, applied with a rocking motion to all parts of the surface, the superfluous ink being wiped off with muslin. The process called *retroussage* is then applied. This consists of passing soft muslin lightly all over the plate, especially in those parts requiring more *force*, gently dragging the ink over the edges of the lines, and thereby softening them. It is precisely this process which requires superior skill and judgment, and it is this process which constitutes the difference in the printing of an etching and a steel engraving. AQUATINT: This is a process by which the acid is allowed to attack large portions of the plate instead of lines. It is really etching by tones, and produces something of the effect of a wash drawing in Indian ink. The plate is only partially protected by a ground composed of asphaltum dust or resin dissolved in spirits of wine. The spirit evaporates, and leaves a thin even coating of dust or grain. The acid attacks the plate in the interstices, producing a flat tint. The variations of forms and tones are obtained by stopping out, as in etching. The tones may be further varied and modified by means of the burnisher. The etched line may be used in conjunction with aquatint, and in some aquatints an outline is first etched to give force and character to the work. SOFT GROUND ETCHING: In this process the ordinary etching ground is used, mixed with about half its weight of lard, more or less, according to the temperature of the air. The ground is laid with a dabber in the same way as an ordinary etching ground, and afterwards smoked with a taper. Thin paper is strained on the plate when cold. The drawing is made on the paper with a lead pencil. On removing the sheet, the paper takes up the varnish which adheres to it. The plate is then bitten in the usual way. The paper employed should have some grain, as a smooth paper gives no result whatever. The print which is obtained gives something of the appearance of a lead pencil or crayon drawing. DRY POINT: Theoretically this is the simplest of all forms of engraving, since nothing but a metal plate and a hard cutting point is needed. The actual practice, however, is far from simple. The design is drawn upon or cut into the bare metal with a point sharpened to a flat cutting edge. The point not only ploughs into the metal (copper usually), but raises a ridge or burr which catches the printer's ink and gives a soft, velvety effect in the proof. The amount of burr raised by the etching point depends

as much upon the angle at which the point is held as upon the amount of pressure exercised. A point held at an angle of, say, 45° will give more burr than that held perpendicularly with the same amount of pressure. Dry point plates will not yield a large number of prints, even when the plate is steel faced, as the burr wears away. Dry point is employed as an auxiliary to the bitten line, and elaborate etchings are generally finished with the dry point; but in this case the burr is removed by means of the scraper. SAND GRAIN: This process is used by some etchers with good results, but always as an auxiliary to the etched line. A ground is laid as for etching; a sheet of sandpaper is then laid face downwards on the plate, which is passed through the printer's press with sufficient pressure for the grains of sand to pierce the ground. The plate is then stopped out and bitten in the usual manner. Subjoined is a list of the more famous of the earlier engravers and etchers:

CHROMOXYLOGRAPHY.

Wood Block Engraving and Printing in Colour.

As in the case of wood engraving, this art came to us from the East. It is quite a recent art so far as Western nations are concerned, and up to the present the practice of it is almost entirely confined to this country. There is a general consensus of opinion amongst artists that the quality and texture of a chromolithograph, or indeed of any process of oil colour printing, is unpleasant and unsatisfactory compared with the beauty of surface and quality of a Japanese colour print. A few years ago experiments and inquiries were made by a little band of artists in London into the Japanese methods of engraving and printing in colour, with the result that a number of very successful prints have been produced, and classes have been formed for instruction in this branch of art at the Central School of Arts and Crafts in Regent Street and at other places. The Smithsonian Institute of Washington has issued a pamphlet giving details of the process, with photographs and drawings of the various tools and materials, and a certain amount of interest has therefore been aroused in the United States. The process is as follows: The wood employed is cherry or pear, cut *plankwise* instead of in transverse section, as in the case of box. The design is drawn upon thin tissue paper and pasted face downwards upon the wood. A careful cutting along both sides of the lines of the design is then made, a small knife being used instead of a burin or graver. The knife resembles a small chisel sharpened to an angle. The wood between the cut lines is then hollowed out with curved chisels, leaving the lines in relief, as in ordinary boxwood engraving. An impression of this is then taken upon Japan paper. This is called the key block, and is usually printed in Indian ink. Impressions from this key block are then pasted down upon fresh blocks, and the different colours of the design cut, necessarily in flat tints. A separate block or printing is necessary for each colour, although if a particular colour should occupy only a portion of the block, another colour may be cut upon the remaining portion of the same block. With care *both sides* of a plank may be utilised. It is necessary to have a system of register marks, in order that each print may fall in the right place during printing. *No mechanical means whatever are used in printing.* The colours employed are dry powder colours, mixed only with water and a little rice paste, and applied to the block by means of a large flat camelhair brush. Pressure is applied by means of a small flat pad or rubber made of some kind of soft leather, held in the hand and rubbed smartly backwards and forwards on the back of the paper, which is carefully placed upon the block. The paper, which is of a particular quality, made from the bark of the mulberry tree, is easily procurable in London, and should be placed between damped sheets of blotting paper before being used. The paper should, however, be first sized with gelatine size applied with a flat brush.—G. W. R.

Enharmonic Change (*Music*). The substitution of one or more notes for others practically the same; *e.g.* B for C♭, or A♭ for G♯.

Enharmonic Interval (*Music*). One less than a semitone. It cannot be obtained on keyed instruments, such as the pianoforte; *e.g.* C♯ and D♭ are the same note.

Enlargement (*Photo.*) A large print (or more rarely a negative) made from a smaller one by the use of an enlarging lantern. This is a form of optical lantern (*q.v.*) in which the small negative required to be enlarged is used in place of a slide, and the image is thrown on a sensitive surface, such as carbon or bromide printing paper. When a sufficient exposure has been given, the print is developed in the ordinary way.

Enol Form *or* **Enolic Form** (*Chem.*) Compounds which contain the group $- CO - CH_2 - CO -$ behave in certain reactions as if this group had the constitution $- C.OH = CH - CO -$; the latter is called the ENOL or ENOLIC FORM. Examples: ETHYL ACETOACETATE (*q.v.*), $CH_3CO . CH_2 . COOC_2H_5$, behaves in some reactions as if it had the formula $CH_3 . COH = CH . COOC_2H_5$. ACETONYL ACETONE (*q.v.*), $CH_3CO . CH_2 . CH_2COCH_3$, in some reactions behaves as if it had the formula $CH_3 . COH = CH . CH = C . OH . CH_3$. *See* TAUTOMERISM.

En Quads (*Typog.*) Spaces exactly half of an em, so that two en's (n's) equal one em (m).

Enrichment (*Architect. and Build.*) A general term for ornamental devices added to any structure or design.

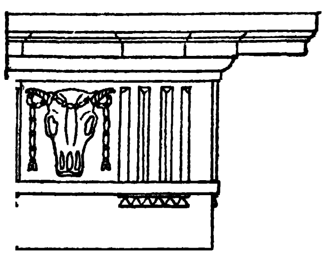
Enrichment of Coal Gas. *See* GAS MANUFACTURE.

Ensilage. A process of preserving green fodder for cattle by storing it in a SILO or pit, under pressure, without having previously dried it.

Ensor (*Lace Manufac.*) A very ingenious method of making net upon the Levers lace machine, invented by the late Mr. F. R. Ensor of Nottingham. It is double warp, and similar in appearance to Brussels net, but neither system of threads is traversed.

Enstatite (*Min.*) Magnesium silicate, $MgSiO_3$. Silica = 60, magnesia = 40 per cent. The variety BRONZITE contains up to 12 or 14 per cent. of iron. In various dull shades of green, grey, and brown. Rhombic; also massive and lamellated. It is one of the ortho-rhombic pyroxenes. *See* PYROXENE. From Northumberland and several parts of Scotland, Norway, France, etc.

Entablature (*Architect.*) The upper division of an order, above the columns, consisting of the cornice, frieze, and architrave. *See* COLUMN, ARCHITECTURE (ORDERS OF), CORNICE, FRIEZE, ARCHITRAVE, *and* BROKEN ENTABLATURE.



ENTABLATURE. ROMAN DORIC.

——. (*Eng.*) A plate or frame carrying some part of a machine (or other structure) which is fixed at some height above the baseplate and supported by struts or columns.

Entasis (*Architect.*) The swelling of a shaft beyond the form of a truncated cone. The delicate entasis used by the Greeks was just sufficient to prevent the shaft looking hollow, the curvature of the columns in the Parthenon being about ½ inch in 31 ft. In Roman work the entasis is obvious, instead of being hardly perceptible as in the case of the Greek columns. *See* ARCHITECTURE, ORDERS OF.

Ente (*Her.*) Various forms of dividing lines similar to indented lines, but curved instead of angular.

Entering Drill *or* **Tap** *or* **File** (*Eng.*) A drill, tap, or file, etc., which is used for the first approximate roughing out of a hole to its shape, but not for giving it its final form.

Entering, Passing, *or* **Drawing In** (*Silk Manufac.*) A process of drawing the warp thread by thread through the mail of mounture or eye of heddle. The various forms of entering are the "straight" pass, "skip" pass, "return" or "point" pass, "space" pass, "stage" pass, and "irregular" pass. STRAIGHT PASS: Entering the threads in regular succession through the eyes of the heddles. SKIP PASS: Entering through alternate heddles; *i.e.* if on eight shafts, taking the first, third, fifth, and seventh in succession, then the second, fourth, sixth, and eighth. RETURN OR POINT PASS: Entering in succession straight up the harness, and then straight down the harness. SPACE PASS: Entering several threads in succession on one shaft. STAGE PASS: Entering through more than one set of heddles for fabrics having mixed plain effects, such as Tabaret. IRREGULAR PASS: Any form of undefined entering to meet the requirements of certain fabrics. *See* HEDDLE, MAIL, MOUNTURE.

Entresol (*Architect.*) *See* MEZZANINE.

Entropy (*Heat*). That property of a body which remains constant when there is no communication of heat, but which increases when heat enters and diminishes when heat leaves the body.

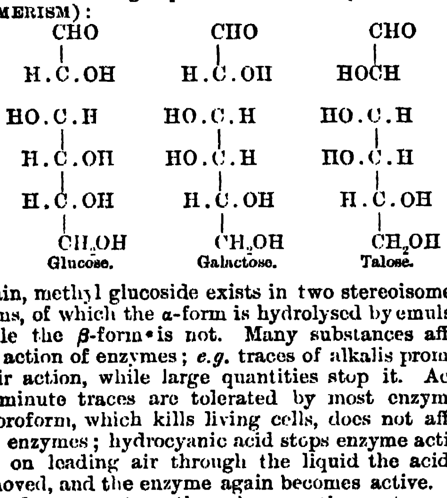
Entry, Right of (*Hygiene*). By the Act of 1891 the Sanitary Authority has the right to enter any premises for the purpose of examining as to the existence thereon of any nuisance liable to be dealt with summarily under the Act, at any hour by day, or in the case of a nuisance arising in respect of any business, then at any hour when that business is in progress or is usually carried on. The term "day" is defined as the period from 6 a.m. to 9 p.m. Practically the same power is given by the 1875 Act to officers of Local Authorities outside London. The main distinction is with reference to time of entry. In regard to private houses the officers shall be admitted at any time between the hours of 9 a.m. and 6 p.m., or in respect of any business, then at any hour when such business is in progress or is usually carried on. If entry is refused, a justice may grant a warrant upon application by the Sanitary Authority. Occupiers may require the person claiming the right to enter to produce some written document, properly authenticated on the part of the Sanitary Authority. The power of entry may be exercised by any members or officers of the Sanitary Authority, or persons authorised by them generally or in any particular case.

Envelope. (1) The bounding or covering surface of a solid. (2) A curved line (or surface) which is touched by every member of a series or family of curves.

Envelopes, Cometary (*Astron.*) Jets of incandescent material are thrown off from the nucleus of a comet as the sun is approached, and these jets form a series of concentric envelopes like hollow shells, one within the other, round the nucleus.

Enzymes *or* **Unorganised Ferments** (*Chem.*) Substances of entirely unknown constitution; they are probably related to the albumins—some (*e.g.* pepsin) more than others. Like albumins, they are precipitated from their solutions by alcohol and by certain salts, such as ammonium sulphate. They are colloids: as albumins are coagulated by heat, so, on boiling, enzymes lose their activity. They are produced in the living cells of plants and animals, and are obtained from these by various methods. *See* DIASTASE, EMULSIN, ZYMASE. They are very wide-

spread in nature, and are divided into classes according to the kind of action they produce; *e.g.* zymase hydrolyses monosaccharides; invertin hydrolyses disaccharides; diastase hydrolyses polysaccharides; and emulsin hydrolyses glucosides. Rennet coagulates albumin. Other enzymes, *e.g.* pepsin, convert albumin into the diffusible peptones; others bring about oxidation, and others reduction. All enzymes have the power of resolving hydrogen peroxide into water and oxygen. An enzyme has the property of acting upon a quantity of substance incomparably greater than its own mass; but its power in this direction is limited, and the action is never a complete one; *e.g.* emulsin cannot hydrolyse the whole of a given quantity of amygdalin at once; but if, when the action has stopped, ***the products of hydrolysis be removed***, the action will continue. This suggests that the change is a reversible one; and it has been shown in the case of the enzyme maltase that it not only resolves maltose into dextrose, but also changes dextrose to maltose. An enzyme of one class cannot effect the same change as an enzyme of another class; even slight differences in structure affect the activity of an enzyme; *e.g.* zymase ferments glucose readily, galactose with difficulty, and talose not at all. These stereoisomerides are represented by the following spacial formulæ (*see* STEREOISOMERISM):



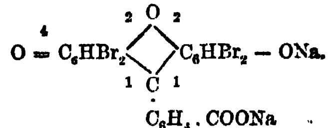
Glucose. Galactose. Talose.

Again, methyl glucoside exists in two stereoisomeric forms, of which the α-form is hydrolysed by emulsin, while the β-form is not. Many substances affect the action of enzymes; *e.g.* traces of alkalis promote their action, while large quantities stop it. Acids in minute traces are tolerated by most enzymes; chloroform, which kills living cells, does not affect the enzymes; hydrocyanic acid stops enzyme action, but on leading air through the liquid the acid is removed, and the enzyme again becomes active. As regards temperature, there is an optimum temperature at which the enzyme acts best. Enzyme action is catalytic, *i.e.* the enzyme itself remains unchanged after the action. Certain metals in a fine state of division acquire enzyme-like properties: such are platinum, iridium, gold, etc. To obtain the metals in this state the electric arc is made to pass under water between poles of the metal. In this way platinum gives a dark brown liquid in which the fine particles of metal are held in a state of suspension. This liquid decomposes hydrogen peroxide, traces of alkali promote its action, traces of acid do the same. It inverts cane sugar; it converts it at 150° into alcohol and carbon dioxide; it loses its enzyme-like properties on stronger heating; it is "poisoned" by hydrocyanic acid, and recovers its active properties on passing air through the solution. These metallic "solutions" have been named INORGANIC FERMENTS.

Eocene (*Geol.*) The lowest subdivision of the Tertiary Rocks. The name is based on the fact that marine fossiliferous rocks of this age contain a small percentage of molluscan species which are living in the same part of the Earth at the present day, and which may be regarded as ***marking the dawn*** (whence the name) of the present molluscan fauna. The British succession, stated from the top downwards, is as follows: Bracklesham Beds, Bagshot Sands, London Clay, Oldhaven Beds, Woolwich and Reading Beds, Thanet Sands.

Eolith (*Geol.*) A name applied to broken flints or other kinds of stone which are supposed to bear some distant resemblance to rude weapons shaped by human agency. The name was given because they were thought to be the earliest stone implements fashioned by primitive man, and therefore of older date than palæoliths.

Eosin (*Chem.*)



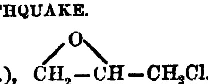
The sodium salt, or the corresponding potassium salt, of tetrabromfluorescein. Bluish red crystals; a dilute solution in water shows green fluorescence; a strong solution is bluish red. Acids precipitate the dye as a yellowish red solid. Used as a red dye for wool, silk, paper, biscuits. It is prepared by brominating fluorescein in alcoholic solution. The potassium salt of tetrabromofluorescein ($C_{20}H_6Br_4O_5 . K_2 + 6\ H_2O$) was one of the first substances employed in conjunction with ammonia for the preparation of orthochromatic plates sensitive to yellow green rays.

Eosine Colours. *See* DYES AND DYEING.

Epicalyx (*Botany*). An outer whorl of leafy structures in a flower, formed either by a series of bracts (*e.g. Mallow*) or by the fusion of the stipules of the sepals (*e.g. Strawberry*).

Epicentrum. *See* EARTHQUAKE.

Epichlorhydrin (*Chem.*),



A liquid smelling like chloroform; boils at 117°; insoluble in water. It is obtained from both dichlorhydrins (*see* GLYCERINE) by the action of caustic potash.

Epicyclic Gear (*Eng.*) Any gearing in which the centres of one or more of the wheels are not fixed to the frame of the machine, but describe circles. The DIFFERENTIAL GEAR (*q.v.*) used in motor cars is an example.

Epicyclic Train (*Eng.*) A set of EPICYCLIC GEAR (*q.v.*)

Epicycloid (*Eng., etc.*) The curve generated by any point in a circle which rolls round the outside of another circle. The teeth of ordinary gear wheels are formed of portions of epicycloids.

Epidemic (*Hygiene*). The term "epidemic" signifies a disease affecting a great number of people at a certain time. The disease may be distributed over a large area or confined to a particular community. It may recur in epidemic form from time to time, with intervening periods of complete immunity. *Cf.* ENDEMIC.

Epidermis (*Botany*). The external layer of cells in plants. The confluent outer walls form the cuticle, and this is, in some plants, greatly thickened.

Epidermis (*Zool.*) The outer portion of the skin or other covering of an animal, composed of one or more layers of cells. These layers are very numerous in the higher animals, and the outer layers give rise to hair, nails, etc.

Epidiorite (*Geol.*) A basic schistose rock, primarily of eruptive origin, which has undergone dynamic metamorphism, resulting in the conversion of the pyroxene it originally contained into one of the amphiboles. In many cases the parent rock was an intrusive sheet of dolerite. It is a common form of schist amongst the metamorphic rocks of the Scottish Highlands, as well as in those of other areas which have had a similar history.

Epidote (*Min.*) A basic calcium aluminium iron silicate, $H_2O . 4CaO . 3(Al . Fe)_2O_3 . 6SiO_2$. Monosymmetric. Colour, pistachio green to blackish green. It is an important rock-forming mineral, and occurs widely distributed. Some of the finest crystals are from Arendal, in Norway; also from the Western Islands of Scotland, the Urals, the Pyrenees, etc.

Epigraph. (1) An inscription. (2) A sentence or quotation at the commencement of the chapters of a book to indicate the sentiment or idea.

Epigyny (*Botany*). The condition in a flower when the thalamus, or flower axis, completely invests the ovary, leaving only the style and stigma exposed.

Epinaos (*Architect.*) The rear porch of a Greek temple. *See* CELL.

Epiphysis (*Zool.*) The end portions of a bone, separated from the shaft by a plate of cartilage in which are bone-making cells. By the addition of bone to the shaft and epiphysis, longitudinal growth is obtained.

Epiphyte (*Botany*). Plants which fix their habitation upon other plants without deriving food from them, as, for example, the orchids, certain species of which perch upon the branches of trees.

Epistyle (*Architect.*) *See* ARCHITRAVE.

Epithelium (*Zool.*) A tissue concerned chiefly in the process of SECRETION (*q.v.*) It consists of thin sheets of cells, and forms the epidermis, the lining of cœlom, alimentary canal, blood vessels, and the various ducts. There are two kinds—the SQUAMOUS or SCALY, and the COLUMNAR type.

Epsomite (*Min.*) Native Epsom salts; hydrous magnesium sulphate, $MgSO_4 . 7H_2O$. Rhombic; also in incrustations. Colourless or white. It is a common constituent of many natural mineral waters; it also occurs as an efflorescence on rocks which contain magnesium. From Epsom, Spain, Clausthal in the Harz, United States, etc.

Epsom Salts (*Chem.*) *See* MAGNESIUM COMPOUNDS *and* EPSOMITF.

Equation of Time (*Astron.*) *See* MEAN SOLAR DAY.

Equation, Personal (*Astron.*) Skilled observers note the passage of a star across a wire of a transit instrument, too late or too early, by an amount that is different for each observer, but nearly constant for each.

Equations (*Chem.*) *See* CHEMICAL EQUATIONS.

Equator, Celestial (*Astron.*) The great circle of the celestial sphere drawn halfway between the poles; it is that in which the plane of the earth's equator cuts the celestial sphere.

Equatorial (*Astron.*) A large telescope with an axis parallel to the axis of the celestial sphere, and rotating at the same rate by means of clockwork. A star once brought into the field of view then remains in the field as long as required. A second axis at right angles to the first enables the telescope to be adjusted to the correct altitude at the commencement of the observation.

Equatorial Radius of the Earth. *See* RADIUS OF THE EARTH.

Equator, Terrestrial. A great circle on the earth at right angles to the axis through the poles.

Equerre *or* **Escarre** (*Her.*) Used by French and German heralds for a charge resembling the "canton." Called also in ancient times "Angulus." A corner of a shield cut off by an elbow shaped band of another tincture.

Equilateral Arch (*Build.*) A pointed arch constructed on an equilateral triangle.

Equilibration (*Eng.*) BALANCING (*q.v.*)

Equilibrium (*Mech.*) The condition of two or more forces which, when acting together on a body, produce no motion.

——, **Neutral** (*Mech.*) The condition of a body when in equilibrium which is neither stable nor unstable. A sphere or cylinder resting on a horizontal plane is in neutral equilibrium.

Equilibrium Ring (*Eng.*) A ring of metal fitted to the back of a large slide valve, and making a smooth fit or contact with the back of the valve chest; or fixed to the inside of the valve chest, and making contact with the back of the valve. The space inside the ring is kept in communication with the exhaust, thereby diminishing the pressure on the valve and rendering it easier to move.

Equilibrium Slide Valve (*Eng.*) A slide valve in which the steam pressure is relieved by an EQUILIBRIUM RING or some other means.

Equilibrium, Stable (*Mech.*) A body is in stable equilibrium if, after receiving a small displacement, it returns (or tends to return) to its original position; *e.g.* a sphere resting inside a hollow sphere is in stable equilibrium.

——, **Unstable** (*Mech.*) A body is in unstable equilibrium if, after receiving a small displacement, the forces which act on it tend to increase its displacement. A sphere poised on the top of another sphere is in unstable equilibrium.

Equinoctial Points (*Astron.*) The points at which the ecliptic cuts the celestial equator. They are termed respectively the FIRST POINT OF ARIES and FIRST POINT OF LIBRA, though, owing to precession, they no longer lie in the constellations from which they take their names.

Equinoxes (*Astron.*) The dates when the sun crosses the equator; *i.e.* March 21st (the Vernal Equinox) and September 23rd (the Autumn Equinox). The day and night are then of equal duration.

Equipolle (*Her.*) A French charge resembling "Chequy," only the number of the squares is limited to nine. The centre and four corner squares differ from the four other squares in tincture.

Equipotential Surface (*Phys.*) A surface, either real or imaginary, every part of which is at the same potential (*q.v.*) The surface of a conducting body is always an equipotential surface so far as concerns electric forces.

Equisetum *or* **Horsetail** (*Botany*). A genus of fern plants growing in swampy places, and having jointed stems with whorls of slender branches. The stems of one species are used, under the name of DUTCH RUSHES, for polishing. Silica is abundant in the cell walls.

Equivalence (*Chem.*) Another term for VALENCY (*q.v.*)

Equivalent (*Chem.*) The equivalent of an element is that weight which will combine with, or displace from combination, one part by weight of hydrogen. The equivalent of an element is the same as the quotient (atomic weight ÷ valency). The equivalent of a non-metal can be found by analysis of its hydrogen compounds, that of a metal by finding the weight of hydrogen displaced by a known weight of the metal from an acid, or in case the metal is not acted upon by an acid in such a way as to set free hydrogen, by converting a known weight of the metal into an oxide, weighing the oxide, and calculating the equivalent from the fact that 8 parts by weight of oxygen are equivalent to 1 part by weight of hydrogen.

Equivalent Focal Length (*Photo.*) A term applied to a compound lens. The equivalent focal length of a compound lens is equal to the focal length of a single lens, which would produce the same magnification of a distant object as the compound lens under consideration.

Equivalent Lens (*Phys., etc.*) A lens is equivalent to a given combination of lenses if, when placed in the position of the one on which light first falls, it produces the same deviation in the axis of an eccentrical pencil as the combination does. The expression "equivalent lens" is at times also used to denote a single lens of the same focal length as a combination of lenses.

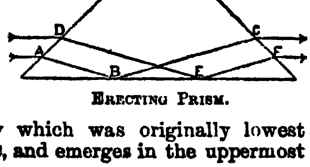
Equivalent Points of a Lens (*Light*). *See* PRINCIPAL POINTS.

Erased (*Her.*) When a charge is left with rough or jagged edges (three in number) as if violently torn off. If trees are shown thus the term is *eradicated*. It is the converse of COUPED.

Erbium (*Min.*) Does not occur native. It exists in combination in the following minerals:—Double salts: Fergusonite, Fluocerite, Euxenite, Polycrase, Yttrotantalite, Nohlite, and Cyrtolite. Fluoride: Yttrocerite. Niobate: Sipylite. Phosphates: Rhabdophanite, Scovillite. Silicate: Cenosite, Eucrasite.

Erechtheum. A famous Ionic temple dedicated to Athena Polias, the guardian of the city of Athens. It was situate on the Acropolis, to the north of the Parthenon, and was remarkable for its architectural variety, one of the most notable features being the Porch of Caryatids. Portions of the sculptures which decorated the structure now form part of the Elgin marbles in the British Museum.

Erecting Prism (*Light*). A glass prism, usually having one angle of 90° and two of 45°. If parallel rays be incident on one face at A and D, they are refracted to B and E, where they undergo total internal reflection, emerging at C and F. The ray which was originally lowest follows the path ABC, and emerges in the uppermost position; hence a beam from a lantern, which would otherwise produce an inverted image on the screen, can be caused to produce an erect image. This device is much used when an erect image is required of an object which cannot be placed in an inverted position in the lantern.



ERECTING PRISM.

Erecting Shop (*Eng.*) The department of an engineering works where the component parts of machines are put together. It usually contains no machine tools, but has a travelling crane for moving heavy work, and small hand tools used in the final fitting together of the separate parts of the work.

Erg (*Phys.*) The unit of work in the centimetre-gram-second system: the amount of work done when a force of 1 dyne is overcome through a distance of 1 centimetre.

Ergot (*Botany*). *Claviceps purpurea*, a fungus parasitic upon the grain of cereals, especially rye. The fungus absorbs the tissues of the ovary or young grain, and then forms a compact violet mass termed a SCLEROTIUM, or, in pharmacy, ERGOT.

Erica (*Botany*). The "heaths" form a genus of the *Ericaceæ*. *E. scoparia*, a native of the South of France, has a stout rootstock used for making "briar" wood (= BRUYÈRE WOOD) pipes.

Ericaceæ (*Botany*). An order of dicotyledons of widespread distribution. Their habit ranges from small woody plants to shrubs and trees. Well known genera are the HEATHS (*see* ERICA), ARBUTUS, and RHODODENDRON.

Eriodendron (*Botany*). The silk cotton tree (*E. anfractuosum*) belongs to the order *Bombacaceæ*: it is a native of tropical America. The silky hairs surrounding the seeds are used as stuffing for cushions.

Eriophorum (*Botany*). The cotton sedge, order, *Cyperaceæ* (*Monocotyledones*) has a perianth of bristles around the female flowers. These hairs are used as a stuffing for cushions, etc.

Ermine (*Her.*) (1) A tincture representing white fur with black spots. The spots take various conventional forms, typical of the black tail end of the ermine. (2) The animal itself.

—— (*Zool.*) The ermine (*Mustela erminea*; fam. *Mustelidæ*) is the stoat in its winter fur; the fur in summer is reddish brown. It is closely allied to the weasel. The white fur which forms the ermine of commerce is chiefly obtained from Alaska. The black tips of the tails of the animals are arranged on the skins at intervals for effect. Formerly portions of the tails of black lambs were used instead. The fur is used in this country more especially as trimming on the robes of judges and peers.

Ermines (*Her.*) A tincture representing fur similar to ermine, but reversed; *viz.* white spots on black fur.

Erminois (*Her.*) A variation of the fur, *i.e.* on a field "or," spots "sable." The reverse of erminois is called PEAN; *viz.* a field "sable" with spots "or."

Eros, Asteroid (*Astron.*) The name given to a minor planet discovered in 1898. It is the most important of this class of bodies, as it comes so close to the earth at times that it affords the most precise means of determining the solar parallax, from which the distance of the sun is deduced.

Erosion (*Geol.*) A term applied to any one of the natural processes by which rocks of any kind are wasted away. This includes chemical erosion, as well as the waste effected by prolonged exposure to the action of glaciers, rain, rivers, frost, blowing sand, the waves of the sea, etc.

Erratics (*Geol.*) A term now restricted to rock fragments of any dimensions, which have been transported from their native locality to another part by the action of moving ice. The term BOULDER is nearly or quite synonymous in geological terminology with the term Erratic.

Error of a Chronometer. The amount by which it is wrong when it indicates noon (0h. 0m. 0s.) If the clock is slow, the error is reckoned positive; if fast, negative.

Erubescite (*Min.*) A sulphide of iron and copper, $3Cu_2S_3 . Fe_2S_3$. Copper = 50 to 71, iron = 6·5 to 18, sulphur = 21·5 to 28 per cent. Cubic, more often massive; colour reddish; metallic, but when exposed it rapidly tarnishes. When in quantity it constitutes a valuable ore of copper. From Central and South America in quantity; also found in Cornwall, Tuscany, Germany, Norway, and the United States.

Eruptive Rocks (*Geol.*) Those rocks which have consolidated from a molten condition. They are usually classified as PLUTONIC, TRAPPEAN, and VOLCANIC ROCKS (*q.v.*)

Eryngium (*Botany*). Our native species grows on the sea shore, and is known as SEA HOLLY (order, *Umbelliferæ*). A tropical species yields valuable fibre. *See* CARAGUATA.

Erythrina (*Botany*). A small Indian tree (*Erythrina indica*; order, *Leguminosæ*) cultivated as a support for the pepper plant, and also as a shade for coffee shrubs. *E. umbrosa*, a taller tree, is used in South America to protect cocoa plantations.

Erythrine (*Min.*) A hydrous arseniate of cobalt, $Co_3As_2O_8 . 8H_2O$. Oxide of cobalt = 37·5, arsenic acid = 38·5, water = 24·0 per cent. Nickel may replace some of the cobalt. Monosymmetric; more often it occurs as a powdery incrustation of a crimson red colour. Cornwall, Alston Moor, Saxony, Bohemia, Norway, France, Missouri, etc.

Erythritol *or* **Erythrite** (*Chem.*) $CH_2OH . (CHOH)_2 . CH_2OH$. White solid, crystallising in prisms; is optically inactive; has a sweet taste; is very soluble in water; melts at 126°. Its behaviour is that of a tetrahydric alcohol. It occurs free in *Protococcus vulgaris*, and combined with orsellinic acid in many lichens and in some algæ. It may be obtained from lichens by saponification with milk of lime, out of contact with air. By cautious oxidation with dilute nitric acid it yields the aldehyde ERYTHROSE, $CH_2OH(CHOH)_2CHO$. Its nitrate is used in medicine in Bright's disease.

Erythrosin *or* **Iodeosin** (*Chem.*) Has the same formula as EOSIN (*q.v.*), except that the bromine of the latter is replaced by iodine. Soluble in water, giving red solutions, which do not fluoresce. It dyes wool and silk a bluish red colour. It may be obtained in a similar manner to eosin, using iodine in place of bromine. The free acid may be used in moist ether solution in titrating very dilute normal solutions (down to $\frac{1}{1000}n$) when all other indicators fail; it can also be used in titrating alkaloids. It is employed in orthochromatising gelatine plates; but since the shade of the dye is bluer, the position of maximum sensitising action lies nearer the D line in the spectrum. *See also* DYES AND DYEING.

Erythroxylum (*Botany*). Order, *Erythroxylaceæ*. A tropical American genus and order. The well known Coca tree is a member of this genus. *See* COCA.

Escallop (*Her.*) A single shell of a bivalve mollusc belonging to the pecten genus. Its serrated edge is its characteristic feature. Pilgrims brought these shells back with them from the shrine of St. James at Compostello; thus the escallop became the badge of a pilgrim or palmer.

Escapement (*Watches and Clocks*). That part of a watch or clock that checks the advance of the going train, and at intermittent intervals allows the energy of the motive power to "escape" to the balance or pendulum. *See* CHRONOMETER, CYLINDER, DEAD BEAT, DETENT, DUPLEX, GRAVITY, LEVER, PALLETS, RECOIL.

Escarpment (*Geol.*) The more or less steep outer edge formed by an inclined bed of rock which is of a more durable nature than the bed above it and that below. For example, the English Chalk, which is more durable, on the whole, than the overlying Tertiary strata or than the underlying Gault, forms an escarpment around the landward margin of the Weald, and also across England from Dorsetshire to Yorkshire. In like manner the more durable beds of the Jurassic Rocks form escarpments for a similar reason.

Escartelé (*Her.*) A dividing line which has a square notch in the centre ; rarely used in English heraldry.

Eschallot (*Botany*). A well known vegetable (*Allium ascalonicum*; order, *Liliaceæ*) introduced from Palestine.

Escutcheon (*Her.*) The shield upon which arms are depicted, and sometimes used in a wider sense to denote the whole coat-of-arms, crest, motto, supporters, etc.

Esker (*Geol.*) *See* GLACIAL ACTION.

Espagnolette (*Build.*) A fastening used with French casement windows or sash doors. It consists of an upright metal rod, which is fixed on the meeting style of one leaf of the casement; the rod on being turned by a handle operates two hooks, which form the terminations of the rod, causing them to catch in plates or staples fixed to receive them. There are many varieties of this type of fastener, some forms being reeded, and shooting into sockets at the top and bottom.

Esparto Grass (*Botany*). A North African grass (*Stipa tenacissima*; order, *Gramineæ*) used in the making of cordage, mats, baskets, and especially paper.

Espressivo (*Music*). Expressively.

Essential Oils. The more volatile oils, as distinguished from the less volatile or FIXED OILS. *See also* OILS.

Essonite (*Min.*) A synonym for CINNAMON STONE (*q.v.*)

Essorant (*Her.*) Describes the attitude of a bird with wings spread as if flying; also termed VOLENT or SOARING.

Establishment (*Typog.*) A term applied to workmen who are employed at a fixed weekly wage, and who are then said to be "stab hands."

Ester (*Chem.*) A compound of an alcohol with an acid; *e.g.* alcohol, C_2H_5OH, unites with acetic acid, CH_3COOH, with elimination of water, forming ethyl acetate, $CH_3COOC_2H_5$, which is also called acetic ethyl ester. A general method of preparing esters is to mix the alcohol and acid together, and act upon the mixture with a dehydrating agent such as sulphuric acid, or hydrochloric acid gas, or zinc chloride.

Estelé (*Her.*) A foreign term similar to decapitated or decollated, *i.e.* having the head cut off, and used chiefly of birds and animals.

Etærio (*Botany*). An aggregation of fruits (drupes, achenes, follicles) derived from a single flower, *e.g.* the mulberry and strawberry.

Etching. *See* ENGRAVING AND ETCHING.

—— (*Glass Manufac.*) Corrosion of the surface of glass by hydrofluoric acid. *See* GLASS MANUFACTURE.

Etesian Winds (*Met.*) Winds of Southern Europe caused by the indraught of the cooler air of the Mediterranean, to replace the heated air which rises from the hot sandy desert of the Sahara.

Ethane *or* **Dimethyl** (*Chem.*) $CH_3 . CH_3$. A colourless, odourless gas, nearly insoluble in water, considerably more soluble in alcohol; liquefied at 93° C. under ordinary atmospheric pressure. Obtained by any of the methods used for the preparation of paraffins (*q.v.*)

Ethene (*Chem.*) Another name for ETHYLENE (*q.v.*)

Ether (*Chem.*) (1) A general name for compounds of the type $R-O-R^1$, where R and R^1 are alkyl radicals which may be the same or different. (2) Sometimes used to designate ESTERS or ethereal salts; *e.g.* acetic ether, nitric ether, etc., are old names sometimes used for ethyl acetate, ethyl nitrate, etc. (3) ORDINARY ETHER is DIETHYL ETHER, $(C_2H_5)_2O$. A mobile liquid with characteristic smell; sp. gr. 0·736; boils at 35°; extremely inflammable, burning with bright flame. Its vapour forms an explosive mixture with air, and when inhaled produces unconsciousness; hence its use in surgical operations. It dissolves in 10 parts of water, and is a valuable solvent for organic substances, such as fats and oils. Its chief reactions are: With strong sulphuric acid it yields ethyl hydrogen sulphate; with hydriodic acid it yields ethyl iodide; with ozone it forms a peroxide. Ether is made by mixing alcohol and sulphuric acid, forming ethyl hydrogen sulphate, and heating the mixture to 140°. If now alcohol be added gradually, the formation of ether is continuous, $C_2H_5HSO_4 + C_2H_5OH = (C_2H_5)_2O + H_2SO_4$. The above is called Williamson's continuous etherification process. On the large scale, benzene sulphonic acid is now much used in place of sulphuric acid.

—— (*Phys.*) The invisible medium assumed to fill all space, by means of which heat, light, and electric waves are propagated. It is not possible to say whether this ether consists of matter in the chemical sense of the word, but it must possess density and elasticity.

Ethereal Salts (*Chem.*) The same as ESTERS (*q.v.*) So called because they may be regarded as ethers in which one alkyl group is replaced by an acid group.

Thus: $\begin{matrix} C_2H_5 \\ C_2H_5 \end{matrix} \Big> O$ Ether. $\begin{matrix} CH_3CO \\ C_2H_5 \end{matrix} \Big> O$ Ethyl Acetate.

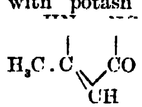
Ethine (*Chem.*) Another name for ACETYLENE (*q.v.*)

Ethoxides (*Chem.*) *See* ETHYLATES.

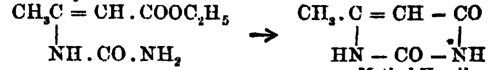
Ethyl (*Chem.*) The name given to the group C_2H_5. It only exists in combination.

Ethyl Acetate, Acetic Ether (*Chem.*) $CH_3COOC_2H_5$. A colourless fruity smelling liquid; boils at 77°. It is hydrolysed by water slowly, much more quickly by dilute alkalis and acids, $CH_3COOC_2H_5 + H_2O = CH_3COOH + C_2H_5OH$. Used to some extent as a flavouring agent. With sodium it gives sodium ethyl acetoacetate. With ammonia it forms acetamide. It is prepared by mixing alcohol and sulphuric acid, adding anhydrous sodium acetate, allowing to stand, and then distilling off the ethyl acetate; or in a similar manner from alcohol, acetic acid, and sulphuric acid; also by the action of acetyl chloride or acetic anhydride on alcohol, $CH_3COCl + C_2H_5OH = CH_3COOC_2H_5 + HCl$.

Ethyl Acetoacetate (*Chem.*) $CH_3CO . CH_2COOC_2H_5$. A pleasant smelling liquid, boils at 181°. It is one of the most important synthetic reagents in organic chemistry. It is prepared by acting upon ethyl acetate with sodium, distilling off excess of the former, acidifying with acetic acid, separating and fractionally distilling the liquid which floats on top after acidifying. It reacts in two ways: (1) as if it has the formula given above; (2) as if it has the formula $CH_3C . OH = CH . COOC_2H_5$. *See* TAUTOMERISM. Probably it is a mixture of much of the former with a little of the latter. Treated with sodium it yields sodium ethyl acetoacetate, $CH_3CO . CHNaCOOC_2H_5$, and this product with an alkyl iodide (RI) gives $CH_3CO . CHR . COOC_2H_5$. The latter with sodium and an alkyl iodide (RI) yields the compound $CH_3CO . CRR^1COOC_2H_5$. These alkyl substituted acetoacetic esters yield KETONES of the form $CH_3CO . CHRR^1$ when treated with dilute alcoholic potash, and ACIDS of the form $CHRR^1COOC_2H_5$ when treated with strong alcoholic potash; *e.g.* act upon ethyl acetoacetate with sodium and ethyl iodide, and obtain $CH_3CO . CHC_2H_5COOC_2H_5$; treat with strong potash and obtain Butyric acid, $C_2H_5 . CH_2 . COOH$. With phenylhydrazine ($H_2N . NHC_6H_5$) acetoacetic ester gives $\begin{matrix} CH_3C = CH . COOC_2H_5 \\ | \\ NH . NHC_6H_5 \end{matrix}$, and this compound ($\beta$-phenylhydrazidocrotonic acid) with potash yields 1:3 phenylmethylpyrazolone,



, a compound which yields ANTIPYRINE (*q.v.*) on treatment with methyl iodide. With urea we have a similar action to that of phenylhydrazine, and on treating the product with potash we obtain METHYL URACIL, a starting point for the synthesis of URIC ACID.



Methyl Uracil.

Ethyl Alcohol (*Chem.*) C_2H_5OH. *See* ALCOHOL.

Ethylamines (*Chem.*) When ethyl iodide is heated with alcoholic "ammonia" in sealed tubes the following substances are obtained: $NH_2C_2H_5 . HI$, ethylamine hydriodide; $NH(C_2H_5)_2HI$, diethylamine hydriodide; $N(C_2H_5)_3HI$, triethylamine hydriodide; $N(C_2H_5)_4I$, tetraethylammonium iodide; NH_4I, ammonium iodide. If this mixture is distilled with caustic potash, ammonia, ethylamine, $C_2H_5NH_2$, diethylamine, $(C_2H_5)_2NH$, and triethylamine, $(C_2H_5)_3N$,

pass over, and on leading them into a tube immersed in a freezing mixture, the ammonia alone escapes condensation. In the distilling flask the hydriodic acid has combined with the potash to form potassium iodide, and the tetraethylammonium iodide remains behind with the potassium iodide. The three amines which have distilled over are now acted upon with ethyloxalate, $\begin{array}{l}COOC_2H_5\\ |\\ COOC_2H_5\end{array}$, when the primary amine forms $\begin{array}{l}CONHC_2H_5\\ |\\ CONHC_2H_5\end{array}$, diethyloxamide, the secondary amine forms $\begin{array}{l}CON(C_2H_5)_2\\ |\\ COOC_2H_5\end{array}$, ethyl diethyloxamate, while the TRIETHYLAMINE remains unchanged, and may be distilled off. The diethyloxamide is a solid, and the ethyl diethyloxamate is a liquid, so that these may be separated by filtration. Each may now be distilled separately with caustic potash, giving respectively ETHYLAMINE and DIETHYLAMINE. ETHYLAMINE is a liquid which boils at 18°. Besides the above method of preparation, it is also obtained when methyl cyanide is reduced by hydrogen, also when nitroethane is reduced by hydrogen, and when propionamide is acted upon by bromine and caustic potash. With nitrous acid it yields ethyl alcohol. In other respects it resembles ammonia very closely indeed. *See also* DIETHYLAMINE *and* TRIETHYLAMINE.

Ethylates *or* **Ethoxides** (*Chem.*) Compounds produced by replacing the hydroxyl hydrogen in ethyl alcohol by metals; *e.g.* when sodium is thrown upon alcohol, we have the reaction $C_2H_5OH + Na = C_2H_5ONa + H$. C_2H_5ONa is sodium ethylate or sodium ethoxide. If the excess of alcohol be distilled off, it remains as a white crystalline solid, which is decomposed by water: $C_2H_5ONa + H_2O = NaOH + C_2H_5OH$.

Ethyl Benzoate (*Chem.*) $C_6H_5COOC_2H_5$. A colourless liquid with smell like pears; boils at 211°. Prepared by saturating a solution of benzoic acid in alcohol with dry hydrochloric acid gas, allowing to stand, and pouring into water, when the ester separates. May also be obtained by the BAUMANN-SCHOTTEN REACTION (*q.v.*)

Ethyl Bromide (*Chem.*) C_2H_5Br. A sweet smelling, colourless liquid; boils at 39°; insoluble in water. Obtained by dropping bromine upon amorphous phosphorus and alcohol, allowing to stand, and distilling. It is an important reagent in organic chemistry.

Ethyl Chloride (*Chem.*) C_2H_5Cl. A colourless, sweet smelling liquid; boils at 12°. Obtained by passing dry hydrochloric acid gas into alcohol containing zinc chloride, the latter serving to take up water; also obtained as a by-product in the manufacture of chloral. Used as a local anæsthetic, it freezes the part to which it is applied.

Ethylene Alcohol (*Chem.*) Another name for ETHYLENE GLYCOL (*q.v.*)

Ethylene Chlorhydrin (*Chem.*) *See* OLEFINES.

Ethylene Dibromide, Ethylene Bromide (*Chem.*)

$$\begin{array}{l}CH_2Br\\ |\\ CH_2Br\end{array}$$

A colourless, sweet smelling liquid, boiling at 131°. It is obtained by passing ethylene into bromine. Heated with alcoholic caustic potash, it yields, according to the amount of potash, VINYLBROMIDE or ACETYLENE.

$$\begin{array}{l}CH_2Br\\ |\\ CH_2Br\end{array} + KOH = \begin{array}{l}CH_2\\ \|\\ CHBr\end{array} + KBr + H_2O$$

$$\begin{array}{l}CH_2Br\\ |\\ CH_2Br\end{array} + 2KOH = \begin{array}{l}CH\\ |||\\ CH\end{array} + 2KBr + 2H_2O$$

See also GLYCOLS.

Ethylene Glycol (*Chem.*) *See* GLYCOLS.

Ethylene, Olefiant Gas (*Chem.*) C_2H_4. A colourless gas; faint sweetish smell; nearly insoluble in water; boils at −169° under ordinary atmospheric pressure. It burns with a bright flame, and with the proper proportion of oxygen (3 vols.) or of air (15 vols.) it forms an explosive mixture. Chlorine unites with it volume for volume, forming ETHYLENE CHLORIDE, $C_2H_4Cl_2$ (Dutch liquid). Bromine does the same; excess of chlorine in bright sunlight gives carbon and hydrochloric acid gas. For other reactions *see* OLEFINES. It occurs in coal gas (about 6 per cent.), being the principal illuminant in it. It may be obtained synthetically by reducing copper acetylide (*see* ACETYLENE) with zinc and ammonia, or in quantity by heating alcohol with sulphuric acid, or ethyl bromide with alcoholic caustic potash. *See* OLEFINES.

Ethylene Series (*Chem.*) *See* OLEFINES

Ethyl Ether (*Chem.*) *See* ETHER.

Ethyl Formate (*Chem.*) $H.COOC_2H_5$. A pleasant smelling, colourless liquid; boils at 54°. Obtained by heating glycerine, oxalic acid, and alcohol together in flask with reflux condenser; then the mixture is distilled. It occurs in rum, and is used in the preparation of artificial rum. It is easily hydrolysed. With zinc alkyls it gives SECONDARY ALCOHOLS.

Ethylidene (*Chem.*) A name given to the divalent group $CH_3.CH=$. Thus CH_3CHCl_2 is ethylidene chloride, a liquid obtained by the action of phosphorus pentachloride on aldehyde.

Ethyl Iodide (*Chem.*) C_2H_5I. A colourless, sweet smelling liquid; boils at 72°. Insoluble in water; turns brown on exposure to light, owing to liberation of iodine. Obtained by *gradually* adding iodine to amorphous phosphorus and alcohol, allowing to stand, and distilling. It is a very important reagent in organic chemistry.

Ethyl Nitrate (*Chem.*) $C_2H_5NO_3$. Colourless liquid; boils at 86°; it explodes when rapidly heated to a high temperature; burns with a bright white flame. Prepared by distilling a mixture of alcohol and nitric acid to which urea has been added to destroy nitrous acid. With tin and hydrochloric acid it yields hydroxylamine.

Ethyl Nitrite (*Chem.*) $C_2H_5NO_2$. A yellowish liquid, smelling of apples; boils at 16°; very inflammable. Prepared by the action of sulphuric acid upon potassium nitrite and alcohol. It is insoluble in water; a solution of the impure nitrite in alcohol constitutes SWEET SPIRITS OF NITRE.

Ethyl Oxalate (*Chem.*)

$$\begin{array}{l}COOC_2H_5\\ |\\ COOC_2H_5\end{array}$$

An aromatic smelling liquid; boils at 186°; does not mix with water. Prepared by heating *anhydrous* oxalic acid, alcohol, and sulphuric acid together in a

flask fitted with a reflux condenser; then pouring into water when the ester separates. With ammonia it gives a precipitate of oxamide. *See also* ETHYLAMINES.

Ethyl Red (*Photo.*) This dye has been strongly recommended by Dr. Miethe as a colour sensitiser for gelatine plates. The absorption spectra of its solution gives two maxima in the yellow green and green.

Etoile *or* **Estoile** (*Her.*) A star with generally six wavy rays. The mullet is also a star, but with five rays, generally plain, not wavy. An estoile may be also of "eight points"; then the rays alternate wavy and plain.

Etruscan Vases. *See under* VASES, POTTERY AND PORCELAIN, *and* GLASS MANUFACTURE.

Etui (*Cost., etc.*) A small case for holding needles, bodkins, toothpicks, etc. Cases of this kind, often of precious metal, chased, were much worn by ladies in the sixteenth and seventeenth centuries, hanging from the girdle. A case for pocket instruments.

Eucalyptus (*Botany*). Eucalyptus (a genus of the order *Myrtaceæ*). The oil of Eucalyptus is obtained by distillation of the leaves of *E. globulus* (blue gum), while the so-called red gum is an exudation from the bark of *E. rostrata*.

Euchlorine (*Chem.*) A name given by Davy to the mixture of chlorine and chlorine peroxide, obtained by the action of hydrochloric acid on potassium chlorate, under the impression that it was a single substance.

Eudiometer (*Chem.*) An instrument used to bring about the union of measured volumes of gases with the view of ascertaining the composition of one of them or of the product of their union. It is a straight glass tube, open at one end and closed at the other; near the closed end two platinum wires are fused into the glass, so that the sparks from an induction coil can be passed in the mixture of gases. It has a millimetre scale etched on the outside of it, and the instrument is calibrated before being used. To use it, the tube is filled with mercury and inverted in a vessel of mercury; the gases are then passed in, the volume being taken and corrected for difference of pressure after the introduction of each gas.

Eugenia (*Botany*). A genus of the *Myrtaceæ*, growing in the tropics. The fruits are valuable either as food or as spices. *See* CLOVES, ALLSPICE.

Eugenol, Eugenic Acid (*Chem.*) $C_6H_3\begin{cases} C_3H_5 & (1) \\ OCH_3 & (3) \\ OH & (4) \end{cases}$

An oil smelling like cloves; boils at 247°: it reddens litmus; gives blue colour with ferric chloride. It occurs in oil of cloves (85 per cent) and in oil of cinnamon. It is obtained from oil of cloves by shaking with alcoholic potash: this gives the potassium salt of eugenol; it is washed with alcohol and decomposed by an acid.

Euonymus (*Botany*). The dried bark of the root of the Wahoo tree (*Euonymus atropurpureus*; order, *Celastraceæ*) is the source of the drug Euonymin. *E. japonica* is one of our familiar evergreen shrubs. *E. europæus* is the common SPINDLE TREE.

Euphorbia (*Botany*). A genus of *Euphorbiaceæ*, of varied structure and habit. Many have a cactus-like form, but are distinguished by the presence of latex (*q.v.*) The acrid juice has many medicinal properties.

Euphorbiaceæ (*Botany*). A natural order of *Dicotyledons*, having a wide distribution and variety of habit. The presence of latex is common in the order. Many economic plants belong to the *Euphorbiaceæ*, such as CROTON, MANIHOT, HEVEA, CASTOR OIL (*q.v.*)

Eustachian Tube (*Zoology*). The passage leading from the pharynx to the tympanic cavity of the middle ear. Its function is to equalise pressure of air on either side of the tympanic membrane.

Eustyle (*Architect.*) The name given to the spacing of the columns in a Grecian temple when the space between the columns is equal to two and a half times the lower diameter of the shaft. *See* ARÆOSTYLE, PYCNOSTYLE, SYSTYLE, DIASTYLE, *and* INTERCOLUMNIATION.

Evaporation (*Phys.*) The process by which a liquid changes into a gas or vapour.

——, **Natural** (*Meteorol.*) Water exposed to the air evaporates at a rate which depends on the HYGROMETRIC STATE of the air (*q.v.*) When the air is nearly saturated, evaporation is slow; when the air is dry, it is rapid. In any given area the total amount of evaporation is almost always less than the rainfall.

Evaporators (*Chem. Eng.*) Any form of plant for removing moisture. Usually applied to plant used for concentrating liquids, as distinguished from plant for drying solids. Multiple evaporators are generally operated under a vacuum, and may be either single, double, or triple EFFECTS (*q.v.*) Vacuum evaporators are chiefly used in the sugar industry and the concentration of soap leys in the manufacture of glycerine. Their use is also spreading in the chemical trade for concentrating caustic solutions, etc.

Evaporimeter (*Met.*) An instrument for determining the amount of water evaporated in free air in a given time. Piche's instrument is simple and effective.

Evection, Lunar (*Astron.*) A term used with regard to the motion of the moon, and depending on the alternate increase and decrease of the eccentricity of the moon's orbit.

Evening Star (*Astron.*) A star setting near the sun, but just afterwards.

Even Pitch (*Eng.*) A screw in which the number of threads per inch is equal to that on the leading screw of the lathe on which it is cut, or is equal to that number multiplied by a whole number. In cutting a screw of even pitch, the right position of the tool for each fresh cut is readily found without turning the change wheels into any definite position.

Evolute. *See* INVOLUTE.

Excavation (*Eng.*) The digging out of earthy material (accomplished by hand labour or by mechanical means) and its removal to a suitable position. If the material is removed from under water, the operation is termed DREDGING.

Excavator (*Eng.*) A mechanical digging machine used in the construction of canals, railway cuttings, etc.

—— (*Civil Eng.*) Machinery for excavating; there are two main types, one consisting of an endless chain carrying iron or steel buckets which strike the ground in succession, removing a quantity of material each time; the other consisting of one

large scoop attached to a long lever: this type is usually termed a STEAM NAVVY.

Excentric (*Eng.*) A modified spelling of ECCENTRIC (*q.v.*)

Excitation (*Elect. Eng.*) The magnetising of the field magnets of a dynamo or motor by the passage of a current through the coils of wire on the limbs or cores of the field magnets. The current is either obtained from the machine itself in SELF-EXCITING DYNAMOS or is supplied from a separate source, in SEPARATELY EXCITED DYNAMOS. *See also* DYNAMO.

Exergue (*Coins*). The space on the reverse side of a coin or medal which lies below the principal device; it sometimes bears a *secondary inscription*, etc. On modern coins the date and engraver's initials generally occupy this position. The term is also applied to such *inscription*, date, etc.

Exhaust (*Chem. Manufac.*) The thorough extraction of a soluble body from insoluble ones by solvents, *e.g.* oil from seeds, sulphur from spent oxide, etc.

—— (*Eng.*) (1) The escape of steam or waste gases from an engine cylinder after expansion. (2) The waste gases themselves.

—— (*Phys. etc.*) The creation of a more or less perfect vacuum.

Exhaust Gases (*Eng.*) In a steam engine the exhaust gases consist of steam after it has expanded in the cylinder; it is cooler, at a lower pressure, and more charged with moisture, or "wetter" than on its entrance to the cylinder. In gas and oil engines the exhaust gases consist of the products of combustion, together with any unburnt gases remaining after the explosion.

Exhausting Fan (*Eng.*) A FAN (*q.v.*) used for pumping air out of any space or chamber.

Exhaust Lap (*Eng.*) *See* LAP *and* SLIDE VALVE.

Exhaust Line (*Eng.*) *See* INDICATOR DIAGRAM.

Exhaust Pipe (*Eng.*) The pipe which conveys the waste steam (or other gases) away from the cylinder.

Exhaust Port (*Eng.*) The opening which leads the waste gases from the cavity under the slide valve to the exhaust pipe. If the slide valve of an ordinary steam engine were removed, this port would be seen to lie between the two steam ports. *See also* STEAM ENGINE.

Exhaust Silencer (*Motor Car*). *See* SILENCER.

Exomis (*Archæol.*) A vest or short tunic without sleeves, worn by Greek and Roman artisans and slaves. It was fastened over the left shoulder, but passed under the right arm, leaving that arm and shoulder uncovered and free.

Exothermic Compound (*Chem.*) A compound in the formation of which from its elements heat is evolved. The majority of compounds are exothermic.

Expanding Bit (*Carp., etc.*) A boring bit capable of cutting holes of various sizes at will. There is a fixed central point which guides the tool, and a cutter carried on a radial arm, which can be set at a given distance from the axis of the bit. A very useful tool, especially when holes are required which differ a little from any standard size.

Expanding Metal (*Eng.*) Alloys of bismuth, which have the property of expanding on solidifying.

Expansion (*Eng.*) In general, any increase in the dimensions of a body; in particular, the increase in volume of the steam (or other gases) in an engine cylinder after the admission of steam has stopped, or after firing the charge in the case of a gas engine.

Expansion (*Phys.*) The increase in dimensions of a body; in particular, the increase in length, area, or volume produced in a body by raising its temperature. These three forms of expansion are termed LINEAR, SUPERFICIAL, and CUBICAL EXPANSION respectively. The coefficient of expansion is the increase per unit length, area, or volume of a body when heated 1°. If a, β, and γ represent the coefficients of linear, superficial, and cubical expansion respectively, l_o, a_o, v_o the length, area, and volume of a body at 0°, l_t, a_t, v_t the values of the same quantities at $t°$, then we have the following equations:

$$l_t = l_o\ (1 + at)$$
$$a_t = a_o\ (1 + \beta t)$$
$$v_t = v_o\ (1 + \gamma t).$$

Also it can be shown that

$$\beta = 2a$$
$$\gamma = 3a.$$

The values of a (within ordinary ranges of temperature) for some common substances are as follows:

Brass	·0000189
Copper	·0000166
Glass	·000009
Iron	·0000112

The coefficient of cubical expansion (γ) is ·00018 for mercury, and very approximately ·00366 for gases.

Expansion Curve *or* **Line** (*Eng.*) The part of an INDICATOR DIAGRAM which shows the relation of the pressure and volume of the steam, etc., in the cylinder during expansion. *See* INDICATOR DIAGRAM.

Expansion Engine (*Eng.*) Any engine using expansion in the cylinder. This may be taken to be universal in modern engines.

Expansion Gear (*Eng.*) The devices used to regulate the amount of expansion of steam in a cylinder; *e.g.* LINK MOTION, CORLISS GEAR (*q.v.*)

Expansion Joint (*Eng.*) A form of joint in pipes, etc., which allows a certain degree of movement, in consequence of longitudinal expansion, without breaking the joint. Various devices are used: a sliding socket joint, or a corrugated hoop, or pair of plates, or sometimes a simple bight or bend inserted between two straight lengths of pipe.

Expansion Rollers (*Eng.*) Rollers on which one end of a long girder rests in order to allow of the movement necessary during expansion and contraction, as the temperature changes, without disturbing the structure of which the girder forms a part.

Expansion Tank (*Eng.*) The cistern into which hot water pipes used for heating are fitted. It provides sufficient capacity to allow for the increase in volume of the water as the temperature rises.

Expansion Valve (*Eng.*) A valve which controls the CUT OFF (*q.v.*) of an engine; it is usually a separate slide valve, which stops the admission of steam to the main slide valve.

Expansive Working (*Eng.*) The use of EXPANSION in an engine; now practically universal.

Explosion. In general, the sudden combustion of any violently inflammable substance.

—— (*Eng.*) (1) The destruction of a boiler by the pressure of the steam becoming too high. (2) The FIRING of the CHARGE in a gas engine. *See* IGNITION.

Explosion Chamber (*Eng.*) The part of the cylinder of a gas engine in which the compressed charge is ignited.

Explosion Engines. *See* GAS ENGINES *and* PETROL ENGINES.

Explosion Wave. *See* EXPLOSIVES.

Explosives. Substances which can be made to undergo chemical change with great rapidity; the change is accompanied by the development of a large amount of heat, and the products of the change occupy a very much larger volume than that of the explosive itself. To learn something of the structural conditions of an explosive, consider ozone: it contains three oxygen atoms united thus, $\overset{O}{\underset{O-O}{\diagup\diagdown}}$; ordinary oxygen contains two oxygen atoms united thus, $O=O$. Ozone is unstable, being formed from oxygen, which is very stable, with absorption of heat. When ozone reverts to oxygen its heat of formation is set free, and we have an increase of volume, two volumes of ozone yielding three volumes of oxygen. But ozone under ordinary conditions is not an explosive; it is not possible to obtain gaseous ozone free from admixture with large volumes of oxygen, so that the change to oxygen is slow, the heat developed is feeble, and the change of volume small. With *liquid* ozone the case is different: it can be decomposed by shock, and the decomposition is rapid, the heat development considerable, and the change of volume from *liquid* ozone to *gaseous* oxygen is very great: it is an explosive. The union of nitrogen with oxygen is the basis of all practically applied explosives. The oxides of nitrogen $\left(\begin{matrix}N\\ |\\ N\end{matrix}\!>\!O,\ N-O,\ N\!\begin{matrix}\nearrow O\\ \searrow O\end{matrix}\right)$, though they are endothermic compounds (*q.v.*), are not explosives. But when this union of oxygen with nitrogen occurs in certain solid and liquid compounds, we have powerful explosives. NITRATES contain the group $-O-N\!\begin{matrix}\nearrow O\\ \searrow O\end{matrix}$ examples of explosives containing this group are gunpowder (*q.v.*), nitroglycerine (*q.v.*), and guncotton (*q.v.*), and combinations containing them, such as CORDITE. *See* DYNAMITE, BLASTING GELATINE. NITRO COMPOUNDS contain the group $-N\!\begin{matrix}\nearrow O\\ \searrow O\end{matrix}$: examples of explosives containing this group are the picric acid (*q.v.*) explosives (such as LYDDITE and MELINITE) and FULMINATING MERCURY. The power of these explosives is due to the facts (1) that on firing a large volume of gas is produced, (2) that strongly exothermic compounds are produced. Thus in the case of gunpowder, carbon dioxide and nitrogen are produced, and much heat is developed in the formation of potassium sulphide, carbon dioxide, and nitrogen. The reaction speed of a mechanical mixture such as gunpowder is not so great as that of a definite compound, such as nitroglycerine, guncotton, or picric acid; hence its disruptive effects are not so great—it is rather suited for the propulsion of projectiles. On firing an explosive such as mercury fulminate, the sudden pressure developed gives rise to what is known as an EXPLOSION WAVE, which in this case is propagated at a speed of about 1,600 mètres per second. This explosion wave propagated in the neighbourhood of endothermic compounds such as acetylene or cyanogen is sufficient to explode them.

Exposure (*Photo.*) The act of exposing or allowing the light to act upon a sensitive plate, etc.; also the time during which the light is allowed to act.

External Characteristic (*Elect. Eng.*) The curve showing the relation of the current flowing through the external circuit to which a dynamo is connected, and the potential difference between the terminals. *See* DYNAMO.

External Firing (*Eng.*) Heating a boiler by a firebox entirely outside the boiler itself, instead of in a flue or an internal firebox. The method is confined to early types, and is now rarely used.

External Screw *or* **Thread** (*Eng.*) An ordinary screw cut on a cylindrical surface. Also termed a MALE SCREW or MALE THREAD.

Extincteur (*Chem.*) An instrument used to extinguish small fires. It consists of a metal case containing carbon dioxide under pressure, generated in the vessel itself by the action of dilute sulphuric acid on sodium carbonate, and it allows of a jet of the gas being directed upon the fire.

Extraction of Oils. A method of obtaining oils by means of highly volatile solvents, such as benzene, carbon bisulphide, benzol, sulphuric ether, etc., which rapidly dissolve the fats contained in the seed meal and are afterward driven off completely by distillation, leaving the oil intact. The solvent is almost wholly recovered for further use.

Extractors (*Chem. Eng.*) Apparatus for the extraction of fats, oils, etc., by solvents (such as benzol carbon bisulphide, etc.), which are recovered by distillation and condensation.

Extrados (*Build.*) The upper curved side of an arch. *See* ARCH.

Extraordinary Ray (*Light*). *See* DOUBLE REFRACTION.

Extras (*Typog.*) Charges involved in composition in addition to the fixed price per page of text, such as for setting in foreign languages, tabular work, headings, etc.

Extra Weft (*Woollen Manufac.*) A special colour of weft yarn applied to the fabric, distinct from the ordinary or ground weft.

Eye (*Eng.*) A loop at the end of a rod or bolt.

—— (*Joinery, etc.*) The centre of a scroll.

—— (*Mining*). The top of a shaft.

Eye of a Furnace (*Glass Manufac.*) The recess containing fuel in the middle of the bed of a furnace, at the bottom of which are placed the fire bars or grating.

—— (*Met.*) The bright red spot in the hearth of a blast furnace seen through the nose of a tuyère by means of the mica-faced sight hole placed on the angle of the elbow connecting the blast main with the tuyère.

Eyepiece (*Phys., etc.*) Portion of the eye end of a telescope, microscope, etc. Sometimes known as an "Ocular."

Eyepiece Micrometer. *See* MICROMETER EYEPIECE.

F (*Chem.*) The symbol for FLUORINE (*q.v.*)

—— (*Music*). The fourth note of the scale of C.

f. (*Music*). Abbreviation for "forte": loud.

Fa (*Music*). The sol-fa syllable for F.

Fabrikona (*Dec.*) *See* CANVAS WALL COVERINGS.

Façade (*Architect.*) An external face of a building; generally used to denote the principal external face.

Face (*Eng.*) The principal or most important surface of an object, *e.g.* the graduated surface of a dial.

—— (*Min.*) An individual plane of a crystallographic form. *See also* SYSTEMS OF CRYSTALS.

Face Chuck (*Eng.*) A flat disc shaped chuck furnished with bolt holes and slots. Work can be fixed to the chuck by means of bolts passed through these holes.

Face Lathe (*Eng.*) A lathe which can take in a piece of work of very large diameter, but not of great length: used for turning large discs, wheels, armatures or field magnets of dynamos, etc.

Face Plate (*Eng.*) *See* FACE CHUCK.

Face Plate Coupling (*Eng.*) A COUPLING (*q.v.*) consisting of two castings with flat flanges, by means of which two shafts can be connected by bolts.

Face Side (*Join.*) The first surface of a piece of wood which is trued up. A mark is put on to distinguish it from the other sides.

Facet. (1) One of the faces of a gem where it has been cut and polished by a lapidary. (2) One of the faces of a natural or artificial body that has a series of such faces.

Facing (*Eng.*) A raised surface or projection on a casting, to which some additional part is to be fitted. This raised surface is much more easily machined, filed, etc., than a portion of the main general surface would be, and hence adds to the convenience of manufacture.

Facing Bar *or* **Work Bar** (*Lace Manufac.*) A smooth iron plate about 4 in. wide and the full width of the lace machine, over which the web of lace travels on its way to the roller.

Facing Paviors (*Build.*) Hard burnt malms of good colour and shape. Used for superior walls. *See* BRICKS.

Facings (*Build.*) (1) The best bricks, picked for the face of the work. (2) The stone dressings to door and window openings.

Facing Sand (*Foundry*). Sand mixed with coal or charcoal dust, used for covering the surfaces of a mould which are exposed to the molten metal. A thick coat of this sand prevents the formation of a skin of silicious matter on the casting.

Factor of Safety (*Eng., etc.*) In any structure the load which would break it down is several times as great as the safe load; the ratio of the Breaking Load to the Working Load is termed the FACTOR OF SAFETY.

Faculæ (*Astron.*) Bright portions on the solar disc which can generally be seen in the region of the spots, especially when near the limb of the sun.

Faenza Ware (*Pot.*) A distinctive term given to a fine sort of pottery originally made at Faenza near Bologna, in Italy. The majolica produced there was very beautiful; the plates (called "tondini") have wide rims and deep centres, and are adorned with arabesques and biblical and classical scenes.

Fagot (*Met.*) A bundle of bars of wrought iron which are welded up into a solid mass; this is afterwards hammered and rolled out into a new bar. By this means the fibre, or grain of the iron can be arranged to run in any required direction, and greatly increased strength is obtainable.

Fagoting (*Met.*) The process of welding up a FAGOT (*q.v.*)

Fah (*Music*). Fourth degree of scale in "Movable Doh" system.

Fahlerz (*Min.*) A synonym for TETRAHEDRITE (*q.v.*)

Fahrenheit's Scale (*Heat*). The scale in which the freezing point of pure water is marked 32°, and the boiling point 212°. The zero—32° below the Freezing Point—was based on an imperfect experiment, making the scale very inconvenient. It is now superseded for scientific purposes by the Centigrade Scale.

Faïence, Faience, Fayence, *or* **Fayance** (*Pot.*) The old French term, under which were comprised all descriptions of glazed earthenware, inclusive of porcelain, and to a certain extent this continues so, corresponding in its general use to the English word "crockery" (*Marryat*). Any pottery not transparent is generally termed "Faience." *See also* MAJOLICA.

Falchion (*Arms*). A short broad sword, curved, and with the outer edge sharpened: used in the Middle Ages. Later, the name has been applied to a sword of any kind. Used as a charge in Heraldry.

Faldstool. An armless folding chair sometimes used by bishops. It resembles a camp stool, but is more elaborate. A movable folding-desk: a Litany stool.

Fall (*Build.*) The inclination of a drain, gutter, etc.

—— (*Eng.*) (1) The slope given to a channel intended to carry water. (2) The quantity of water passing over a weir, mill race, etc.

—— (*Mining*). Material accidentally dislodged from the roof or sides of a working.

Falling Mould (*Joinery*). In hand-railing, the development in elevation of the centre line of the rail.

Fall Tube (*Air Pump*). *See* AIR PUMP.

False (*Her.*) Another term for VOIDED—*i.e.* with centre open.

False Bedding (*Geol.*) An inclined arrangement of the layers constituting rocks of sedimentary or of Eolian origin, which has resulted from their being deposited by currents which have varied much in their transporting power from time to time. The most striking and typical examples are those produced by the drifting action of the wind upon sand in desert regions or under similar conditions; but changeable currents of water often give rise to similar phenomena. The direction of slope of the false bedding planes coincides with the direction of movement of the transporting agent.

False Bottom (*Eng., etc.*) A removable bottom placed over the real or fixed bottom of a vessel in order to facilitate cleaning or other operations, or to economise the firing in a grate.

—— (*Chem. Eng.*) Usually a perforated plate which supports the contents of a boiler or kettle, in order to leave a space at the bottom of the vessel in which condensation products, drainings, etc., may collect, out of contact with the contents. It also

prevents the choking of draw-off cocks by the solids under treatment.

False Core (*Moulding*). A movable part of a mould or core, similar to a drawback (*q.v.*), which can be taken out in order to facilitate the lifting of the pattern.

False Key (*Eng.*) A KEY (*q.v.*) formed by a round pin driven into a hole drilled parallel to the axis of a shaft, half of it being in the shaft and half in the hub or boss of the wheel which has to be keyed on. It is much inferior to a key of the usual rectangular section.

False Relation (*Music*). The disagreeable effect produced by the close proximity of two chords having no relationship and belonging to different keys, but having a note in the first chord chromatically altered in the second and sounded in a different part.

Fan (*Cost.*) A small well known instrument for moving the air. The use of the fan was common amongst Eastern nations as far back as history reaches. In early times the fan used out of doors served the purpose of a parasol, and screened the face. Folding fans as now generally used were introduced in the seventeenth century.

—— (*Eng.*) Consists essentially of a set of radial blades rotating at a high speed, and enclosed in a case which is provided with suitable openings for the entrance and exit of air. In fans for producing a blast (used for furnaces and forges) the plane of the blades is parallel to the axis of the fan, but in fans used for exhausting or for ventilating a room by sucking or pumping air out, the plane of the blades is usually inclined to the axis in a similar manner to the blades of a screw propeller. In the latter case the flow of air is parallel to the axis of the fan: in the former it is at right angles to the axis.

—— (*Her.*) A winnowing basket: notable example on the Setvans or Septvans brass.

Fan Cooling (*Motor Cars*). A small fan, worked by the motor, is sometimes used to drive a current of cool air on to the outside of the cylinder to keep it cool, or to draw air through the condenser or radiator for the purpose of cooling the water which circulates round the cylinder and through the radiator.

Fan Curb (*Chem. Eng.*) *See* CURB.

Fancy (*Woollen Manufac.*) A roller in the carding machine, also termed "fly," for brushing up the wool on to the surface of the clothing of the main cylinder.

Fang (*Build.*) The portion of iron railings built into the wall.

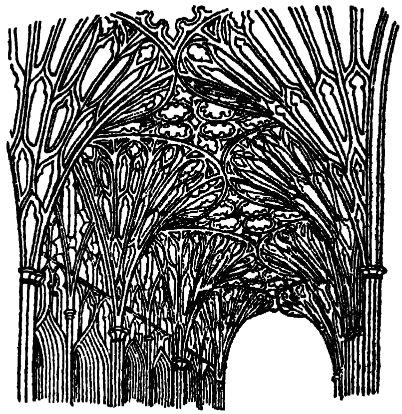
—— (*Mining*). A passage for conducting air along a working.

Fang Bolt (*Eng., etc.*) A bolt with pointed teeth formed on the nut. These teeth sink into wood through which the bolt passes, and prevent its rotating. The bolt itself is turned (like an ordinary wood screw) in order to screw it up.

Fanlight (*Joinery*). (1) The sash above a door. (2) The lights above the transom of a solid frame.

Fan Structure (*Geol.*) A term now restricted to such arrangements of highly disturbed strata as may be likened to the relative position of the leaves in a half opened book lying on its back, or to a pack of cards which is gripped by one edge and opened out at the other. Fan structure is rarely met with except within the cores of what are (1) now, or (2) formerly were, the inner parts of great mountain ranges, such as (1) the Alps of Switzerland, (2) the Southern Uplands of Scotland.

Fan Vaulting (*Architect.*) A species of vaulting peculiar to the Perpendicular style of English gothic architecture. The earlier gothic vaults consisted of constructional ribs supporting a thin filling, but in fan vaulting a return was made to the Roman method of vault construction, as the whole vault was often formed of jointed masonry on which the ribs were carved. Fan vaulting consists of a series of inverted



FAN VAULTING. GLOUCESTER CATHEDRAL, CIRCA 1450.

concave conoids, the semicircular summits of which are separated either by pendants or lozenge-shaped panels acting as keystones. The whole was covered with an elaborate system of panelling. Fine examples can be seen in Henry VII.'s Chapel, Westminster Abbey, and in the cloisters of Gloucester Cathedral. *See* BARREL VAULT, GROINED VAULT, RIB AND PANEL VAULT, *and* SEXPARTITE VAULT.

Farad (*Elect.*) The electromagnetic unit of capacity. A condenser has a capacity of 1 farad if its potential is raised 1 volt by 1 coulomb of electricity. Such a condenser would be of enormous size. The practical unit adopted is the one-millionth part of a farad, and is termed a MICROFARAD: this is about the capacity of 3 nautical miles of submarine cable.

Faraday Effect (*Phys.*) The rotation of the plane of polarisation of a beam of plane polarised light when passed through a magnetic field along the direction of the lines of magnetic force. This effect is one of the fundamental illustrations of the theory of Maxwell that light is really an electromagnetic phenomenon.

Faraday's Ice Pail Experiment (*Elect.*) An experiment for determining the amount and sign of induced charges. A charged ball (or similar object) is lowered into a hollow vessel of conducting material (Faraday used a metal ice pail); the outside of this vessel is connected to an electroscope, by means of which the induced charge is examined.

Faraday Tubes (*Elect.*) The part of a dielectric enclosed within a tubular surface formed by a number of lines of force drawn infinitely close together from the boundaries of an area on which there is a unit charge of electricity.

Fareham Reds. *See* BRICKS.

Farina (*Chem.*) Potato starch. *See* STARCH.

Farnese. The name of the Farnese family has been bestowed upon several notable works of art which were formerly located in the Farnese Palace, Rome, but now form part of the collection in the Museo Nazionale, Naples. Amongst them is the FARNESE BULL, a colossal piece of sculpture attributed to Apollonius and Tauriscus of Tralles, and probably executed about the third century B.C. The group represents the chastisement of Dirce by her stepsons for her ill treatment of their mother, Antiope, by binding her (Dirce) to the horns of a bull. It was discovered in the baths at Caracalla in 1546 and restored. The FARNESE HERCULES, another celebrated Greek statue, is in the same museum. The hero is represented undraped, leaning on his club. The muscular development of the figure is remarkable.

Farthingale (*Cost.*) The large hoops, often of extravagant size, which distended a woman's petticoat or skirt, a sixteenth century forerunner of the crinoline of the nineteenth century.

F.A.S. The delivery of goods FREE ALONGSIDE THE SHIP, *i.e.* at the expense of the person consigning them; the cost of loading is not included.

Fasces (*Archæol.*) The emblem of power carried before superior Roman magistrates by lictors. It consisted of a bundle of wands tied up, with an axe in the centre. The blade of the axe projected through the bundle, and indicated that the magistrate had the power of inflicting capital punishment.

Fascia (*Architect.*) A flat member or moulding similar to a band, but larger, usually used in combination with other mouldings. Ionic and Corinthian architraves usually consist of three fasciæ, each of the upper two of which slightly overhangs the one below it. *See* ARCHITECTURE, ORDERS OF; IONIC; CORINTHIAN; ENTABLATURE; *and* ARCHITRAVE.

—— (*Joinery*). (1) The flat surface below the cornice of a shop front. (2) The board to which the eaves gutter is fixed.

Fascines (*Civil Eng.*) Faggots of wood sunk in marshy ground to support structures for which the soft ground will not provide a sufficiently firm foundation. Used where stone is scarce, but it is not a good method. Willow wood is the best, but brushwood from ash, alder, oak, etc., is also used.

Fast Coupling (*Eng.*) A COUPLING (*q.v.*) in which the shafts are permanently fixed together, so that they cannot be thrown in and out of gear with each other.

Fast Head (*Eng.*) The fixed headstock of a lathe, which carries the mandrel with the speed cone and chucks (*q.v.*)

Fast, *or* Fixed, Needle Surveying. Measurement of horizontal angles by means of a circumferenter without the aid of the magnetic needle. Also called BACKING.

Fast Pulley (*Eng.*) A pulley keyed to a shaft and always rotating with it, as distinguished from a LOOSE PULLEY, which revolves freely on the shaft. Fast and loose pulleys are used side by side, so that a belt can be shifted from one to the other to stop or start a machine.

Fast Red (*Dec.*) A term applied to a series of bright reds, known generally as VERMILIONETTES (*q.v.*)

—— *See* DYES AND DYEING.

Fast Yellow (*Chem., Dyeing*). *See* DIAZO REACTIONS.

Fat Colour (*Dec.*) A term applied to stale mixed paint which has become viscid and greasy owing to exposure to the atmosphere. Fat colour is sometimes used for painting rough work, being thinned down with turpentine or benzene before use.

Fat Edges (*Dec.*) A superfluity or bead of paint on the edge or angle of a surface at right angles to the direction in which the brush is being used, *e.g.* on the styles of a door; the result of careless painting. This fault is one of the signs of incompetence. A professional painter guards against fat edges, and draws his brush in an outward direction, so as to avoid it.

Fathom. *See* WEIGHTS AND MEASURES.

Fatigue, Elastic (*Eng., etc.*) *See* ELASTIC FATIGUE.

Fatigue of Materials (*Eng., etc.*) *See* ELASTIC FATIGUE.

Fat Lime (*Build.*) A nearly pure lime (calcined white chalk).

Fat Liquor (*Leather Manufac.*) An emulsified solution of soap and oil in warm water, used for softening mineral tanned leather. Fish or vegetable oils are generally used with a neutral white soap. Sometimes egg yolk is added to make a better emulsion. First used by Ed. Kent on Dongola leather (*q.v.*)

Fats (*Chem.*) Are compounds of glycerine with acids of the $C_nH_{2n}O_2$ $C_nH_{2n-2}O_2$ .... $C_nH_{2n-6}O_2$, and $C_nH_{2n-3}(OH)O_2$ series. The fats are therefore GLYCERINE ESTERS or GLYCERIDES. A fat is also often named from the acid it contains; *e.g.* glycerine (or glyceryl) tristearate is often called tristearin, or simply stearin. The following are the names, modes of occurrence, and formulæ of some of the more important fats: Glyceryl tributyrate (butter), $C_3H_5(OOC.C_3H_7)_3$; glyceryl tripalmitate (palm oil and lard), $C_3H_5(OOC.C_{15}H_{31})_3$; glyceryl tristearate (tallow and lard), $C_3H_5(OOC.C_{17}H_{35})_3$; glyceryl trioleate (olive oil and lard), $C_3H_5(OOC.C_{17}H_{33})_3$; glyceryl trilinoleate (linseed oil), $C_3H_5(OOC.C_{17}H_{29})_3$; glyceryl triricinoleate (castor oil), $C_3H_5(OOC.C_{17}H_{32}(OH))_3$. The first three are solids, the others liquids. On treatment with superheated steam, or on boiling with alkalis or with sulphuric acid, all fats are resolved into glycerine, and the acid united to it. When an alkali is used, the liberated acid unites with it, and the resulting salt is a SOAP. This process of resolution into glycerine and an acid is called SAPONIFICATION. There is an enzyme, LIPASE (STEAPSIN), which has the property of saponifying fats. It occurs in the pancreas and in the seeds of the castor oil plant, the white poppy, and in linseed and maize. The saponification of fats is carried out on an enormous scale in soap making, in the preparation of fatty acids for candle making, and in the preparation of glycerine. Palmitin, stearin, and olein are used on a large scale in the preparation of MARGARINE. The liquid fats (*e.g.* linseed oil) are often called FIXED OILS. Fats are of great physiological importance. Briefly, their functions are: (*a*) To produce heat; (*b*) to produce energy; (*c*) their distribution in the tissues gives rotundity, and through their non-conducting properties serves to retain the heat of the body; (*d*) aid the removal of effete substances; (*e*) play a considerable part

in the conversion of food into tissue. Owing to their being such great heat producers, fats form a large part of the dietary of persons living in very cold countries. *See* FOODS.

Fatsia (*Botany*). *Fatsia papyrifera* (order, *Araliaceæ*). The source of the rice paper of Japan. The paper is prepared by pressing thin sheets of the pith.

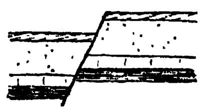
Fatty Acids (*Chem.*) Acids of the series $C_nH_{2n}O$ They are called fatty acids because some of the higher members occur in the fats (*q.v.*) The lower members are liquids; the higher ones, starting with capric acid, $C_{10}H_{20}O_2$, are solids at the ordinary temperature. The lower members are soluble in water; the higher members insoluble in water, but soluble in alcohol and in ether. They all distil in steam. For methods of preparation, see the individual acids, *e.g.* formic, acetic, propionic, butyric, palmitic, and stearic.

Fatty Compounds (*Chem.*) *See* ALIPHATIC COMPOUNDS.

Faucet (*Eng., Build., etc.*) The socket on a cast iron pipe. The name is also applied to a small cock or tap.

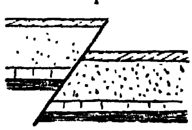
Fault (*Elect. Eng.*) Applied in a special sense by telegraph engineers to a conducting wire, land line, or cable. Faults consist of breakages contact between two lines, electrical connection with the earth (termed WHOLE or PARTIAL EARTHS, according to the degree of completeness of the connection), etc. The detection of faults and the determination of their exact position receive much attention from telegraphists, and many very ingenious methods are employed by which the locality of a fault can often be found within a few yards by an operator perhaps several hundred miles away.

—— (*Geol.*) During the upheaval of part of the crust of the Earth it often happens that a differential movement occurs over a zone of weakness, and the rocks on one side of that zone may be lifted a trifle more than those on the other each time the movement is repeated. Thus a dislocation is caused, and the strata on the same level no longer accord with their counterparts on its opposite side. The downthrow may range up to one of several thousand feet, as is the case with the Pennine Faults, near Appleby.



FAULT.

——, **Reversed** (*Geol.*) In a normal fault the hade or inclination from the vertical of the lower part of the zone of fracture is usually towards the downthrow side of the fault. A vertical shaft passing through the fault could not, therefore, cut the same bed of rock twice. In a reversed fault the hade is in the opposite direction, and it is always the case that some part of the same bed of rock on one side of the fault lies vertically below its counterpart on the other. Reversed faults are generally due to powerful lateral thrusts; but they are sometimes produced by a thrust acting from above downwards.



REVERSED FAULT.

Fault Rock (*Geol.*) The movement, under great pressure, of the rock on one cheek of a fault against the other usually grinds off more or less *débris*, which comes to rest at a lower level, and may be compacted into a breccia (*q.v.*), which is known by the above name. Where the fault fissure is very uneven, masses of considerable size may enter into the composition of the fault rock.

Fe (*Chem.*) The symbol for IRON (*q.v.*)

Feather (*Eng.*) A key, with parallel sides, sunk into and fixed to a shaft. The keyway in the hub of the wheel driven by the shaft makes a sliding fit with the key, so as to allow of relative motion of the wheel and shaft parallel to the axis of the latter. The wheel can slide along the shaft, but must always turn with it.

Feather Edge (*Eng. etc.*) A thin serrated cutting edge which results from the improper grinding of edge tools. Also applied to the "fins" on moulded goods due to the faces of each half of the mould not fitting perfectly, *e.g.* in glass bottles on the sides of the neck and shoulder, owing to a little metal being forced into a thin film between the cheeks of the mould. Mostly found in burst-off bottles or cheap rubber balls and toys.

Feather Edge Boarding (*Carp. and Join.*) Boards that taper or diminish in their thickness from one edge to the other. Used in fencing and in covering the walls and roofs of small wooden buildings, etc.

Feathering Paddles (*Eng.*) Paddle wheels with hinged floats which are caused to enter and leave the water at right angles to its surface. Unnecessary disturbance of the water and consequent loss of power are thus largely prevented.

Feathering Screw (*Eng.*) A SCREW PROPELLER (*q.v.*) whose blades can be turned into a plane parallel to the shaft when the screw is out of use at any time; *e.g.* if the vessel is under sail. Rarely used in modern vessels.

Feathers (*Her.*) Generally those of an ostrich, represented with tips drooping. *See also* PLUME *and* PANACHE.

Feather Trimming (*Textile Manufac.*) Pile fabric woven in stripes.

Feed (*Eng.*) (1) The amount which the cutter of a machine tool is moved at one time, or the rate at which the cutter advances towards the fresh material which is to be removed. (2) FEED WATER (*q.v.*)

—— (*Motor Cars*). The regulation of the supply of petrol to the engine. *See* PETROL ENGINES. In steam cars it refers (1) to the supply of oil to the burner; (2) to the supply of water to the boiler. Both these are usually controlled automatically, but the supply can also be increased or diminished when required by pumps and valves regulated by hand.

Feed Cistern (*Build.*) A small cistern with a ball valve, to supply a boiler.

Feeder (*Foundry*). A mass of fluid metal in a cavity placed at the upper part of a mould and communicating with the space in which the casting is actually formed. It serves as a reservoir of fluid metal to fill up the mould as the casting shrinks or sinks in.

—— (*Met.*) The smaller channels which connect the main channel with the pigs (*q.v.*) when tapping or running off the molten iron from a blast furnace.

—— (*Mining*). A subsidiary vein running into a main vein on the upper side.

Feeding (*Foundry*). Running in a fresh supply of fluid metal during the formation of a large casting. The mould apparently becomes full at the first

pouring, but as the metal solidifies it contracts, and cavities would be left if more metal were not supplied.

Feeding Rod (*Foundry*). An iron rod passed down the holes leading to the cavity of a mould in order to promote the flow of fresh metal during FEEDING (*q.v.*)

Feed Pipe (*Eng.*) The pipe conveying the supply of water to a boiler.

Feed Pump (*Eng.*) A small pump which forces water into a boiler. It is driven either by the engine itself or by a subsidiary or "donkey" engine.

Feed Screw (*Eng.*) A screw used to regulate the feed of a cutting tool.

Feed Water (*Eng.*) The water supplied to a boiler. By measuring its amount, the quantity of steam produced in a given time may be found. Feed water should be clear, free from matter in suspension and in solution.

Feed Water Heater (*Eng.*) A device for warming the feed water, usually by means of the exhaust steam or by the condenser.

Feeling (*Art*). "That visible quality in a work of art which forcibly depicts the mental emotion of the painter, or which exhibits his perfect mastery over the materials of art."—*Fairholt.*

Fehling's Solution (*Chem.*) A solution containing 34·64 grams of copper sulphate, 173 grs. of Rochelle salt, and 84 grams of caustic soda in one litre. The copper sulphate solution is made separately, and a solution of the other substances added to it. It is used as a qualitative and a quantitative test for dextrose, especially in urine. When heated with a liquid containing this sugar, Fehling's solution is reduced; it loses its blue colour, and gives a red precipitate of cuprous oxide. Many other substances reduce Fehling's solution; *e.g.* Lævulose, Maltose, Milk Sugar, Chloral, and Aldehydes generally.

Feigh (*Mining*). Refuse from the ore.

Feints. The first runnings or distillates which come over from a pot still in the distillation of whisky.

Fellmonger (*Leather Manufac.*) One who prepares sheepskins for the tanner by removing the wool. The processes employed to remove the wool is called fellmongering.

Felloes. The rims of wheels: applied chiefly to those which are built up of separate pieces, especially wooden wheels.

Fell of Cloth (*Textile Manufac.*) The last pick of weft forming cloth which is beaten up by the sley; *i.e.* the nearest position of edge of cloth width to reed when weaving in the loom.

Fell Railway (*Civil Eng.*) A railway in which the tractive force is obtained by means of a central rail, which is closely gripped (on both sides) by horizontal wheels attached to the locomotive. This rail has no teeth or projections: but the adhesive power is much greater than in the ordinary system of railway traction, and on the Fell Railway on Mont Cenis trains of thirty-six tons were drawn up a gradient of as much as one in twelve. The two gripping wheels serve as a brake in descending the slopes, and also steady the engine in rounding sharp curves. *See also* MOUNTAIN RAILWAYS.

Felspar (*Min.*) A group of anhydrous silicates of aluminium with varying proportions of calcium, potassium, sodium, and magnesium. These four elements may replace one another in almost any proportion, giving an almost continuous series of varieties, with a gradual transition in physical characters. Some are monosymmetric, some triclinic in their crystalline form. They are an important group of rock-forming minerals. At one end of the series are the POTASH FELSPARS; at the other those which contain much lime. In the middle of the group are the SODA FELSPARS, and between these and either extreme are numerous compounds of an intermediate type. Most eruptive rocks contain one or more of these felspars.

——, **Potash** (*Min.*) A synonym for ORTHOCLASE (*q.v.*)

——, **Soda** (*Min.*) A synonym for ALBITE (*q.v.*)

Felstone (*Geol.*) A name somewhat indefinitely applied to eruptive rocks, allied, in composition, in a general way, to granites. The term is (or was) often used in describing ancient lavas allied to Liparites or to Obsidians, which had become devitrified or stony in texture. It was also used for what would now be termed microgranite, and even for rocks which would now be distinguished as porphyrites. Some of the Scottish rocks formerly classed as felstones are devitrified trachytes or even andesites.

Felt (*Eng.*) Used as a non-conductor of heat for covering steam pipes, etc.

—— (*Paper Manufac.*) An endless woollen blanket used in the manufacture of paper for guiding the wet web of paper to the drying cylinder.

—— (*Woollen Manufac.*) Carded wool made into a wearable texture (*e.g.* carpets, hats, etc.), without weaving, and by fulling or felting.

Felting. The tendency which fibres have to interlock. This tendency is turned to advantage. *See* FELT.

—— (*Woollen Manufac.*) The process of shrinkage which wool and woollen cloths undergo when subjected to moisture, heat, and pressure.

Female Gauge (*Eng.*) A hollow gauge; *i.e.* one used for measuring and adjusting the outside of a piece of work.

Female Screw (*Eng.*) A hollow screw or a nut having an internal thread.

Femme (*Her.*) The heraldic term for wife.

Femur (*Architect.*) *See* MEROS.

—— (*Zoology*). The thigh bone of the leg. It has a rounded lateral head and two prominent ridges—TROCHANTERS—at the upper end.

Fence (*Eng., etc.*) A guide used to keep a cutting tool, and the work operated on, in their proper relative positions. It may be used where the work is moved, as in a circular saw, or where the tool moves, as in a plough (*q.v.*) or a rebate plane (*q.v.*)

Fencing In (*Eng.*) The guarding of moving parts of machines to prevent injury to workmen. It is required by the Factories Acts.

Fender (*Carp.*) A large piece of timber outside the sill of a gantry to protect the structure from injury by passing traffic.

Fenders (*Archæol.*) These were made of rushes, etc., and were placed round wax seals in the fifteenth century to protect them.

Fender Wall (*Build.*) The wall that carries the hearth on the ground floor of a building.

Fenestration (*Architect.*) The arrangement of the windows and other openings in a façade.

Fennel (*Botany*), *Fœniculum officinale* (order, *Umbelliferæ*). A common plant formerly much used as a pot herb. An aromatic oil is distilled from the fruits.

Fenugreek (*Botany*), *Trigonella fœnum græcum* (order, *Leguminosæ*). The seeds are used in veterinary medicine, and as a condiment in India.

Fer de Moline (*Her.*) Another term for MILL RIND; the iron clamp by which a millstone was fixed.

Feretory. A small shrine, often very richly ornamented, in which are placed relics. A portable shrine.

Fergusonite (*Min.*) A metaniobate and tantalate of yttrium, erbium, cerium, uranium, and iron. Tetragonal, hemimorphic, in small brownish black crystals, disseminated in quartz from near Cape Farewell, in Greenland.

Fermata (*Music*). Pause.

Fermentation. The chemical change brought about in organic substances of the most varied kind by: (1) Moulds, such as *Penicillium glaucum*; (2) Saccharomycetes, such as yeast; (3) Bacteria, such as the *Bacillus butylicus*; (4) Enzymes (*q.v.*) The members of the first three classes are known as ORGANISED FERMENTS, because they are living organisms of definite structure. The substance undergoing fermentation is part of the food for the organism, and the substance produced is a waste product of the organism. For an organised ferment to work properly, it must have all the elements necessary to build up its organism in accessible form. The fermenting substance must not be too concentrated, the temperature must be suitable, and the product of fermentation must be removed after it has attained a certain concentration, or the process will stop. The following are examples of fermentation:—ALCOHOLIC FERMENTATION. When brewers' yeast (*Saccharomycetes cerevisiæ*) is added to a solution of cane sugar (which is not too strong, and contains traces of potassium, ammonia, magnesium, calcium, sulphates, phosphates), and the temperature is kept between 25° and 30° C., the sugar is converted by the enzyme invertase, which is present in the yeast, into equal quantities of dextrose and lævulose; the yeast then ferments these two sugars, the dextrose first and the lævulose afterwards, to alcohol and carbon dioxide. Other products are formed also, but in much smaller amount; *e.g.* glycerine, succinic acid, and higher alcohols. These are probably formed by other organisms than the *S. cerevisiæ*. *See also* ALCOHOL *and* ZYMASE. ACETIC ACID FERMENTATION: This is brought about by *Mycoderma aceti* in dilute solutions of alcohol. *See* ACETIC ACID. The souring of wine and beer are examples of this fermentation. LACTIC ACID FERMENTATION: This fermentation is set up in milk by a large number of bacteria, the most important of which is *B. acidi. lactici*. These bacteria ferment the milk sugar (lactose), and the lactic acid produced coagulates the milk (*i.e.* the casein); they can also produce lactic acid from cane sugar and dextrose. *See* LACTIC ACID. The change of urea in urine to ammonium carbonate is due to a *Micrococcus*. For other examples *see* BUTYRIC ACID, SUCCINIC ACID, MANDELIC ACID, *and* LEATHER MANUFACTURE.

Ferments. *See* FERMENTATION.

Feronia (*Botany*). The elephant apple tree (*Feronia elephantum*; order, *Rutaceæ*) of India yields a gum resembling gum arabic. Its wood is also valuable.

Ferricyanide Printing Process (*Photo.*) Paper is coated with a solution containing potassium ferricyanide and a ferric salt (ammonio-citrate). Exposure under a negative (or tracing, etc.) renders the salts insoluble, where they have been acted upon by light. The process is completed by washing with water, when the salts which have not been acted on are removed, leaving white lines on a blue ground.

Ferricyanides (*Chem.*) Salts of HYDROFERRICYANIC ACID, $H_3Fe(CN)_6$ (*q.v.*)

Ferrocyanide Printing Process (*Photo.*) Paper is coated with a solution containing citrate of iron and ammonia, and ferric chloride. Exposure is made in accordance with the ordinary method of contact printing, and the print is developed with a solution of potassium ferrocyanide. When the details have become clear, the print is rinsed and put into dilute hydrochloric acid, giving blue lines on a white ground.

Ferrocyanides (*Chem.*) Salts of HYDROFERROCYANIC ACID, $H_4Fe(CN)_6$ (*q.v.*)

Ferromanganese (*Met.*) A name applied to pig iron with a high percentage (20 or more) of manganese. *See* IRON.

Ferrosoferric Oxide (*Chem.*) TRIFERRIC TETROXIDE, Fe_3O_4. *See* IRON COMPOUNDS *and* MAGNETITE.

Ferruginous. Carrying or charged with iron.

Ferrule. (1) A short tube into which two parts of an object fit. (2) A wooden tube or ring used for making a watertight joint between a tube of a surface condenser (*q.v.*) and the plate into which it fits. (3) An iron ring used in foundry work to support the end of a core.

—— (*Watches, Clocks*). A small pulley used for rotating drills, or pieces of work that have to be turned or otherwise operated on.

Ferrum, Ferric, Ferrous (*Chem.*) *Ferrum* is the Latin name for iron; from it is derived the symbol FE for iron. This metal forms two series of salts, *viz.* (1) FERRIC SALTS, in which iron is trivalent (*see* VALENCY); (2) FERROUS SALTS, in which it is divalent—*e.g.* ferric chloride, $FeCl_3$, and ferrous chloride, $FeCl_2$. *See* IRON COMPOUNDS.

Ferula (*Botany*). A genus of the order *Umbelliferæ*. ASAFŒTIDA and GUM GALBANUM (*q.v.*) are derived from certain species.

Fescue Grass (*Botany*). *Festuca sp.* (order, *Gramineæ*). A large group of grasses of over ninety species. Many of them are valued as meadow and pasture grasses.

Fesse (*Her.*) One of the ordinaries. It is a band occupying the central third part of a shield. *See also* HERALDRY.

Fetter Lock (*Her.*) A padlock and leg iron.

Fettler (*Foundry*). A workman who trims up castings after they are taken from the mould.

Fettling (*Eng., Met., etc.*) (1) Trimming up castings; removing fins, cores, etc. (2) Material used for lining puddling furnaces. It usually consists largely of iron oxides. *See also* BULL DOG.

Fettling (*Woollen Manufac.*) The operation of cleaning the card clothing in scribbling and carding machines.

Fibres (*Botany*). Plant cells which have lost their protoplasm and have their walls thickened and lignified. The cells are usually pointed at the ends, and are often of great length. They constitute the elements of the hard bast (*q.v.*)

Fibrin (*Chem.*) A substance of unknown formula produced when blood clots. It forms tenacious elastic fibres, and is coagulated by heat, alcohol, and prolonged contact with salts. It readily dissolves in acids.

Fibrinogen (*Chem.*) A jellylike tenacious solid of unknown formula: insoluble in water, soluble in salt solutions and in alkalis. It occurs in blood, and is converted by an enzyme (thrombin) present in the white corpuscles into fibrin (*q.v.*) and a small quantity of another albumin.

Fibrous Plaster (*Dec.*) Plaster ornaments usually backed up with canvas and ready for placing in position by the plasterer.

Fibrovascular Bundles (*Botany*). The strands of conducting tissue in the root, stem, and leaves of a plant. The bundle may consist of wood (XYLEM) only, or wood and soft bast (PHLOËM), or CAMBIUM may be present in addition to wood and bast. The prefix "fibro" indicates the presence of hard bast associated with the bundle.

Fibula (*Archæol.*) A clasp or brooch (*q.v.*)

—— (*Zoology*). One of the two bones forming the lower part of the leg, *i.e.* the part between the knee and the ankle. The other bone is the TIBIA (*q.v.*)

Fictile (*Pot.*) Pertaining to pottery or the potter's art.

Ficus (*Botany*). An important genus of the order *Moraceæ*. Many species yield economic products, such as figs (from *Ficus carica*), indiarubber (from *Ficus elastica*). The banyan is also a species of this genus.

Field (*Elect.*) The ELECTRIC FIELD is the space in the neighbourhood of an electrified body, or bodies, in which electrical phenomena are produced by the body. A MAGNETIC FIELD is a space having the same relation to a magnetised body. In both cases the medium filling the space is traversed by the LINES OF FORCE (*q.v.*), and is subject to stresses, which are of the nature of tension along the lines of force and pressure at right angles to them.

—— (*Her.*) The surface of the shield.

—— *or* **Field of View** (*Optics*). The space or area which is visible at one time through a lens or system of lenses.

Fielded Panel (*Carp.*) A raised panel with a flat surface in the centre.

Field Magnets. The magnets producing the lines of force which are cut by the conductors of an armature. *See also* DYNAMO.

Field of View (*Astron.*) The portion of the heavens visible in a telescope.

Field's Syphon Flush Tank (*Hygiene*). Field's flush tank is one of the best in use for automatically flushing sewers and drains. It can be adapted for either purpose. If for sewers, it is built of brickwork; and if for drains it is made of galvanised iron to any required size. It consists of a main tank, with a small chamber beneath. Into this chamber the long leg of the syphon dips after passing through the floor of the tank above. Covering this pipe in the interior of the tank is a bell shaped arrangement, which passes nearly to the bottom. This constitutes the syphon. A tap from the rising main is connected with the tank, and the interval between each flush is regulated by the supply of water from the tap.

Field's Tubes (*Eng.*) *See* BOILERS.

Fiery Mine. One in which explosive gases (FIRE DAMP) are given off.

Fig (*Botany*). *Ficus carica* (order, *Moraceæ*). The dried fruit forms the well known dietary article. It is imported from Smyrna.

Figging (*Soap Manufac.*) A characteristic spotted appearance in soft soaps due to the presence of specks of stearate of potash. Supposed to be an indication of quality, though why is not quite clear, as starch, clay, or steatite is sometimes used to produce a figged appearance in soaps which contain no tallow or other source of palmitic or stearic acids.

Figured (*Her.*) When the human visage is shown, as on the sun.

Figured Bass (*Music*). The bass part only of a composition, with figures above to denote the chords to be added.

Figured Harness (*Silk Manufac.*) *See* MOUNTURE.

Figurine (*Art, etc.*) Literally, a small figure. Applied to small sculptured figures and statuettes.

Filature (*Silk Manufac.*) A superior quality of raw silk reeled by European methods.

File (*Her.*) Another term for LABEL (*q.v.*)

Files. The file is one of the principal hand tools of the engineer and of other metal workers. It consists of a steel blade or body, of very variable form and size, fixed into a wooden handle. TEETH of suitable form and size are cut on the blade, and the latter is hardened and tempered. Files may be classified and described according to their form, use, and the nature of their teeth. Most of the terms used to describe the form require no explanation, *e.g.* parallel, taper, round, half round, three sided, etc. PILLAR and COTTER FILES are narrow files of rectangular section. A RIFFLER is a bent file, used for filing a concave surface. KNIFE EDGED FILES have a section of the form of a narrow V. FEATHER EDGED FILES have a rhombic section, with two very acute and two very obtuse angles. The teeth or CUT of a file may be described as ROUGH, MIDDLE, BASTARD, SECOND CUT, SMOOTH, or DEAD SMOOTH, according to the number of teeth per inch, which range from 12 or 14 to 100, or even more. The teeth of an ordinary file form two sets crossing each other at an angle; this arrangement constitutes the DOUBLE or CROSS CUT. A file with a single set of teeth is usually termed a FLOAT. A SAFE EDGED FILE is one which has one side or edge without teeth. RASPS may be conveniently grouped with files, though their use is chiefly confined to the wood working trades. The form and process of manufacture are similar to those of files; but the teeth consist of "burrs" thrown up by a pointed punch, instead of the straight-edged chisel which is used in making the teeth of a file.

Filigree, Filagree. Delicate metallic lacework, generally gold or silver, formed into ornaments. Filigree work was introduced into Europe from the East by the Italians. Old filigree work was generally ornamented with small beads.

Filler (*Dec.*) *See* FILLING UP.

Fillet (*Architect.*) A small flat face used to separate mouldings or to strengthen the upper edge of a crowning moulding. The narrow band separating the flutes of a column or pilaster. It is also known as a LISTEL.

—— (*Bind.*) A tool used in finishing to produce single, double, and other gilt lines. In England fillets consist of brass wheels which are heated and rolled over the work. On the Continent these tools are mostly flat, and are believed to produce brighter gilding.

—— (*Carp.*) A narrow strip of wood: a flat band.

—— (*Coins*). The ribbon of metal from which the blanks (*q.v.*) are punched.

—— (*Cost.*) A narrow band, generally of some woven material, used to keep the hair in place. Such a band was worn by both men and women in Ancient Greece. *Cf.* DIADEM *and* DIADUMENUS.

—— (*Eng., etc.*) A general term for a narrow band or strip of material, usually projecting above the general level of a surface.

—— (*Her.*) The diminutive of the CHIEF (*q.v.*) *See also* HERALDRY.

Fillet Ground (*Lace Manufac.*) A net with absolutely square holes, similar to canvas, but more defined and "lacey" in appearance. Made upon all descriptions of lace machinery.

Filleting (*Build.*) A band or strip of cement in the angle where the slates on a roof touch the wall, instead of step flashing (*q.v.*)

Filling (*Soap Manufac.*) The treatment of soaps to enable them to carry an excess of water or other weight giving materials, such as paraffin, and petroleum hydrocarbons, without rendering the soap too soft for ordinary use. Cold-made transparent soaps are often heavily filled, and also sugared.

—— (*Woollen Manufac.*) The American term for WEFT YARN.

Filling Up (*Dec.*) The process of bringing a surface to a level before painting or between the application of the coats. Small inequalities are stopped (*q.v.*) with putty, but filling up is always necessary when the surface is uneven. A good filler for a plastered surface is made by mixing fine plaster of Paris, whiting, and warm size. For paint work a mixture of white lead, yellow ochre, and gold size answers well, but a patent filler, manufactured at Merton, is much superior when hard wood such as oak is to be "natural finished" (*q.v.*) A paste filler composed of starch, silex, or some other fine substance, mixed with varnish, etc., is used to fill the grain of the wood.

Fillister (*Carp.*) A rabbet plane with movable fence.

Film. Any very thin layer of material, especially of a flexible nature.

—— (*Photo.*) (1) A thin layer of celluloid coated with sensitive emulsion, and forming a dry plate on which negatives can be made. (2) The actual layer of sensitive emulsion, whether it be supported on glass, paper, or any other material.

Filter. *See* FILTERS.

Filterpress (*Chem. Eng.*) A series of recessed plates, separated by a filter cloth, are arranged in a horizontal frame, which carries the plates or sections. The material to be filtered is passed under pressure into the sections until a solid cake is formed in the plate-chambers, the liquid portion passing away through the filter cloths into a common collecting trough. These presses have been called into existence by the need in the chemical and allied industries for rapid filtration in manufacturing operations. In conjunction with the centrifugal hydro-extractor, the perfecting of these presses constitutes one of the most marked advances in the development of chemical plant by chemical engineering. They are very extensively used for pressing sewage sludge, the lime mud from causticisers, the separation of precipitated pigments in the colour industry, the removal of water from pulp in paper manufacture, and numerous other applications for the separation of solids from liquids in the soap, candle, oil cake, paraffin wax, tar distilling, and general chemical industries. The most modern presses of a certain class provide for the "cake" being washed free from mother liquor *in* the press, without taking the plates apart or handling the material. This is a feature of great importance in some processes, such as the manufacture of zinc white, lithopone, and precipitated chalk, where the separation of the solid in a pure state is the primary object of filtration.

Filters (*Chem., Eng.*) Many special types of filter are employed for the filtration of water for industrial purposes and the purification of manufacturers' waste waters. The majority consist of concrete or iron tanks containing a graduated filter-bed of clinker, gravel, and fine sand, but with special mechanical arrangements for distributing the water evenly over the bed, and periodically washing away the collected impurities. This is effected (after stopping the flow of water) by rapid back-flushing, the fine sand often being loosened and stirred by revolving arms, so that the bed is quickly cleansed with a small volume of water. There are at least six well-known systems in operation, and in some the filter-tank is covered so that the filtration (by gravity) may be accelerated by pressure.

—— (*Hygiene*). To properly perform their function, filters should prevent the passage of pathogenic organisms through their substance; *i.e.* they should sterilise the water. Public supplies are purified by means of beds of sand and gravel. These vary in depth. In the London Water Companies' filters the depth of sand ranges from 1ft. 6in. to 4ft. 3 in. The selection of a domestic filter is of considerable importance, as the use of one which is not competent gives a false security, and may play a conspicuous part in the spread of disease. The best domestic filters are the Pasteur-Chamberland and the Berkfeld.

Filtration. The process employed to separate solid particles from a liquid. In the laboratory circular sheets of unglazed paper are used, the paper being folded into four and supported in a glass funnel. When the liquid attacks paper, a plug of asbestos, guncotton, or glass wool is used. If it is desired to hasten the filtration, the paper may be supported in the funnel by a small platinum cone, and the funnel fitted into a vessel from which the air can be pumped out. In filtering water on the large scale for use in towns, sand and stones are used; a typical filter of this kind is: fine sand, 24 in. in depth; gravel, 12 in.; and boulders, 12 in. The action of a filter of this description is, however, not merely mechanical—a slime forms at the top of the sand in which bacteria grow, using up the bacterial food supply in the water, while the products of bacterial life pass through with the water and largely stop

the growth of bacteria through the filter. In such filters the water is introduced *from below.*

Filtration (*Chem., Eng.*) The industrial applications are many and varied. *See* FILTERPRESS *and* FILTERS.

Fimbria. A fringe.

Fimbriated (*Her.*) Bordered with a narrow band or edge; *e.g.* the white edging which borders the Cross of St. George and the Cross of St. Patrick on the Union Jack or flag of England. *See* UNION JACK.

Fin (*Eng.*) A thin projecting edge on a casting or forging formed by metal forcing its way between the two halves of the mould or die in which the object was cast or forged.

—— (*Zoology*). A flattened expansion of the body in fishes. The paired fins correspond to limbs, while the unpaired fins are merely special swimming organs.

Finder (*Astron., etc.*) A small telescope of low power with a wide field of view, which is attached to large telescopes in such a manner that when a star is approximately in the centre of the field of the finder it is somewhere within the field of view of the large instrument.

Fine Metal *or* **White Metal** (*Met.*) The MATT *or* REGULUS in the later stages of copper smelting, containing 60 to 80 per cent. of copper (*q.v.*)

Fine Stuff (*Build.*) Slaked lime and fine sand, in the proportion of one to two.

Finial (*Architect.*) An ornamental feature at the top of a pinnacle, gable, etc. It is frequently carved to represent a bunch of foliage.

Finish (*Art*). The result obtained by a careful attention to detail in the execution of a work of art.

—— (*Build.*) The last coat of paint, plaster, etc., laid upon any surface.

—— (*Woollen Manufac.*) A special kind of routine of finishing a woollen fabric to obtain a short and lustrous nap or pile on the face by successive boiling and raising.

Finishing (*Bind.*) The gilding, blind tooling, and other ornamentation of book covers.

—— (*Leather Manufac.*) This process includes the seasoning and glazing of leather.

Finishing Cut (*Eng.*) A very fine cut taken in a lathe or machine tool in order to produce a good surface on the finished work.

Finishings (*Build.*) The name given to the joinery fixed in a building.

Finishing Stove (*Bind.*) A gas stove having a large circular plate top and an outside ring. The handles of finishing tools rest upon this ring while the metal ends are being heated on the plate.

Fiords (*Geology*). A term loosely applied to any steep-sided valley, shaped, in the first instance, by rain and rivers, and afterwards lowered so that the sea has been admitted. Those of Norway are typical. In many instances the bottom of a fiord is deeper in the middle than at the seaward end, so that such depressions are more of the nature of lake basins which have been carried, by local subsidence of the Earth's crust, beneath the sea. It has been proposed recently to limit the term fiord to cases of this kind. Drowned valleys in most districts that have been glaciated would then come under this designation. *See* GLACIER.

Fir. *See* WOODS.

Fire Bars (*Eng.*) Castings forming the grating at the bottom of a firebox or furnace. They are made separately to admit of easy removal.

Fire Beacon (*Her.*) An iron basket, with contents alight, on a pole against which leans a ladder.

Firebox (*Eng.*) The part of a boiler which actually contains the fire. *See* BOILERS.

Firebrick Arch (*Eng.*) The structure in a locomotive boiler which deflects the flames and hot gases backward. *See* BOILERS.

Firebricks. *See* BRICKS.

Fireclay (*Geology*). A term applied to any kind of clay that will stand exposure to the high temperature within a furnace without fusing. The essential feature in the composition of such a rock is that it shall contain little or no alkaline matter or any other substance that would tend to act as a flux. Fireclay sometimes occurs in association with beds of coal, but there is no necessary connection between the two kinds of rock. *See* DINAS CLAY.

Fire Cracked (*Pot.*) Ware is described as fire cracked if when removed from the bisque oven a crack is found which is traceable to the bisque firing, and which was not present in the clay stage of its production.

Fire Damp (*Mining*). The coal miner's name for METHANE (*q.v.*)

Fire Damp Cap (*Mining*). The name given to the mantle of burning methane (fire damp) which surrounds the flame of a Davy safety lamp in a fiery mine.

Firedog. *See* ANDIRON.

Fire Door (*Eng., Met., etc.*) The door of a furnace or boiler.

Firelock (*Arms*). An early form of gun, with a lock for producing a spark to ignite the priming: used first in the seventeenth century. The earliest form of gun of this kind was a WHEEL LOCK, the later kind a FLINT LOCK.

Fire Opal (*Min.*) A variety of opal (*q.v.*) showing red and yellow flashes. From Cornwall, Mexico, Guatemala, and the United States.

Fireplaces, Open (*Hygiene*). As a means of heating, open fireplaces are the most expensive in use. They are extravagant because the heat is not all utilised, nor is it distributed uniformly; they give up to the room only a very small portion of the heat yielded by the fuel, the remainder passing up the chimney. They, however, have the great advantage of providing an excellent means of ventilation, and are certainly pleasant in effect. In constructing fireplaces, the following principles, laid down by Teale, should be aimed at: (*a*) As much firebrick and as little iron as possible should be used; (*b*) the back and sides should be of firebrick; (*c*) the back of the fireplace should lean over the fire, while the throat of the chimney should be contracted; (*d*) the bottom of the fireplace should be deep; (*e*) all slits in the bottom of the grate should be as narrow as possible; (*f*) the bars in front should be narrow; (*g*) the space between the floor and the bottom of the fireplace should be closed in front by a close fitting iron shield called an economiser.

Fire Prevention. *See* PREVENTION OF FIRE.

Fireproof Paint (*Dec.*) Paints of various colours in which asbestos is mixed to prevent their ready combustion. The paints are increasing in demand, especially for use in large buildings. So-called fireproof structures are frequently rendered very inflammable by the nature of the interior work and fittings, which, when painted in the ordinary way, cause a spread of fire at the most important point, namely at its inception. CARBORUNDUM (*q.v.*) promises to be very useful in this connection.

Fire Test. *See* FLASHING POINT.

Fire Tube Boiler (*Eng.*) A boiler in which the tubes carry the hot gases, as in a locomotive boiler. Also called a MULTITUBULAR BOILER. It is to be distinguished from an ordinary tubular boiler or a water tube boiler. *See* BOILERS.

Firing (*Eng.*) (1) Attending to the fire in a furnace or boiler. (2) The undue heating of any part of a machine through friction. (3) A general term for ignition, especially the IGNITION OF THE CHARGE (*q.v.*) in gas engines.

—— (*Pot.*) The process of exposing the clay goods to the heat of the kiln.

—— *or* **Ignition Chamber** (*Eng.*) The space in which ignition occurs. *See* GAS ENGINES.

Firing Tools (*Eng., etc.*) The tools used in stoking and trimming a fire.

Firmer Chisel (*Carp., etc.*) A stout chisel, stronger than a paring chisel (*q.v.*), but slighter than a mortising chisel. It is intended to be used by the hand alone, and not, as a rule, with a mallet.

Firmer Gouge (*Carp., etc.*) A gouge similar to a firmer chisel (*q.v.*) in strength, and used in a similar manner.

Firring *or* **Furring** (*Carp.*) *See* FURRING.

Fir Seed Oil. A drying oil made in limited quantities from the seeds of various pine trees. It is sometimes used in paint and varnish making.

Fir, Silver. *See* WOODS.

First Point of Aries (*Astron.*) The point of intersection of the Ecliptic and Celestial Equator, through which the sun passes from the south to the north of the equator. The other point of intersection is called the FIRST POINT OF LIBRA.

First Point of Libra (*Astron.*) *See* FIRST POINT OF ARIES.

First Proof (*Engrav., etc.*) A proof taken from a plate before the inscription, etc., has been engraved upon it. Proofs of this description are generally signed by the engraver, and are of greater value than those printed subsequently. Sometimes termed "proofs before letters."

First State (*Engrav.*) The term is applied to a proof printed from a plate which has not received the final touches, or to a proof, whether finished or not, which differs from the proofs of the second printing.

First Water (*Gems*). Of the highest quality or finest lustre. Applied principally to pearls and diamonds.

Fir Wool (*Botany*). A material in the form of wadding or sheets, made from cotton wool impregnated with an extract of pine leaves. Formerly fir wool was made from the leaves themselves.

Fish (*Her.*) All species are used as charges.

Fish Bellied (*Eng.*) Girders, etc., which are curved so that their lower surface, seen in profile, is convex downwards.

Fished Joint (*Eng.*) A joint made between two rails, beams, etc., by drilling bolt-holes in the ends, bringing the ends together, laying on each side a plate (termed FISH PLATES) having holes corresponding to those in the ends of the rails or beams, and bolting the whole together by FISH BOLTS, or long bolts passing right through the rail and the two plates.

Fish Plates *or* **Fishplates** (*Eng.*) A kind of tie-plate chiefly used for connecting the ends of railway "metals" or rails. *See* FISHED JOINT.

Fishtail Burner. A gas burner giving a flat luminous flame.

F.I.T. Free in Truck; *i.e.* goods which are loaded on trucks at the expense of the consigner.

Fitch (*Dec.*) A small hoghair brush used in delicate decorative work such as lining, picking out ornaments, enrichments, etc. Fitches are made round and flat and also with a bevelled edge, the latter being used for lining (*q.v.*)

Fitchée (*Her.*) Pointed at the end, so that the object may be fixed in the ground.

Fitter (*Eng.*) The workman who carries out the bulk of the hand work in engineering shops. The fitters produce the most accurately finished work on parts which have been more or less correctly shaped with the machine tools.

Fitter's Bench (*Eng.*) A strong bench for handwork.

Fittig's Reaction (*Chem.*) A method of preparing homologues (*see* HOMOLOGOUS SERIES) of benzene. Clean sodium is dropped into a mixture of phenyl iodide (iodobenzene) and an alkyl (*q.v.*) iodide dissolved in dry ether—the flask being kept cool. The following reaction takes place when ethyl iodide is used: $C_6H_5I + C_2H_5I + 2Na = C_6H_5C_2H_5 + 2NaI$.

Fitting (*Eng.*) The hand or bench work involved in the construction and finishing of metal objects in mechanical engineering shops.

—— (*Soap Manufac.*) The treatment of curd soap to remove excess of free alkali. After the "made" soap has separated from the ley, the paste (*q.v.*) is treated as wet steam, which dilutes the ley still entrained in the soap grains. When the desired stage of dilution is reached (coarse fit, fine fit, etc.), the whole stands for about twelve hours, and separates into three layers: at the bottom NEGUR, composed of weak ley, dirt, metallic coloured soaps, and suchlike impurities; at the top a solid crust or FOB of frothy soap; and in the middle the NEST SOAP. Genuine fitted soaps usually contain considerably more water than curd soaps, *i.e.* about 30 per cent. if unsilicated.

Fittings (*Eng.*) (1) The smaller parts of a machine, etc., constructed separately and afterwards added to the main part. (2) The accessories on a boiler-shell, such as safety valve, gauge glass, etc.

Fitting Shop (*Eng.*) The shop where the hand work or FITTING is carried on. Its necessary appliances are a vice, hand tools, gauges, and measuring tools.

Fixed Cutters (*Carp., etc.*) Large tools resembling plane irons fixed in a bench, over which wood is drawn by mechanical power for planing up. The arrangement corresponds to a large inverted plane which is kept fixed while the wood is moved.

Fixed Eccentric (*Eng.*) An ECCENTRIC (*q.v.*) keyed to its shaft; now almost universally used.

Fixed Expansion (*Eng.*) An arrangement or adjustment of the SLIDE VALVE (*q.v.*) of an engine by which the cut off always occurs at the same instant, *e.g.* at one-third of the stroke. An adjustable cut off allowing variable expansion is preferable, as the amount of steam used in each stroke can then be modified to suit the power which the engine is required to develop.

Fixed Oils (*Dec.*) The true oils, *i.e.* glycerides, such as linseed, walnut, poppyseed oils, which are not changed by heating and distillation. They thus differ from the ESSENTIAL OILS (*q.v.*) or volatile spirits, and harden on exposure to the air.

Fixed Pulley (*Eng.*) A pulley keyed to its shaft.

Fixing (*Photo.*) The removal of the unaltered silver salts from the film after development, carried out by means of a solution of sodium thiosulphate (hypo) or with potassium cyanide. These act by forming a soluble double salt with the silver, which readily diffuses out in the washing water.

Fixing Fillets (*Build.*) Slips of wood built in the joints of brickwork to which the joinery is fixed.

Flag *or* **Flagstone.** A paving stone, especially one of those natural stones (commonly sandstone) which split easily into flat slabs suitable for paving. *See* FLAGSTONES.

Flagstones (*Geol.*) Thin beds of sandstone which can be easily quarried in the form of slabs suitable for paving stones or for rough slating. In the north of England a flagstone quarry is often referred to as a slate quarry. The best flagstones are those from the Orcadian or Middle Old Red Sandstone of Caithness and Orkney. Next to these are the Carboniferous Flagstones of the north and midland counties of England. Some of the Jurassic rocks also yield good flagstones.

Flanches (*Her.*) Always in pairs, and formed by two curved lines extending from upper angles of shield to the respective base points, the curves being inwards.

Flake White (*Paint. and Dec.*) The name given to pure, finely ground white lead when especially prepared for artists' use.

Flaking (*Dec.*) A defect in distemper (*q.v.*) in which the paint flakes off, owing to imperfect adhesion with the surface to which it is applied. May sometimes be avoided by adding sulphate of zinc to the distemper.

Flamboyant (*Architect.*) The name given to the later period of French Gothic architecture, contemporaneous with English Perpendicular Gothic. The principal characteristic of Flamboyant work is the flamelike form of the window tracery. In late English decorated work Flamboyant tracery is occasionally used, but this can always be distinguished from the French by the mouldings. *See* DECORATED.

Flame (*Chem.*) A flame is gaseous matter raised to such a temperature by chemical action that it is incandescent. Two kinds of flame may be distinguished—the luminous and non-luminous. The flame of a candle may be taken as a type of the former, and the flame of a Bunsen burner or of a gas stove may be taken as a type of the latter. A candle flame can be seen to consist of (*a*) a blue region at the base of the flame, forming the outside part of the flame; (*b*) a dark inner region surrounding the wick and extending to some distance above it; (*c*) a luminous region exterior to the dark region and interior to the blue region at the base; (*d*) a brownish, nearly non-luminous sheath of small extent surrounding the luminous region above and merging into the blue towards the lower part of the flame. The dark inner region (*b*) consists of gases formed by vaporisation of the fat of the candle; these gases are undergoing decomposition owing to the heat generated by the combustion going on in the two regions (*a*) and (*d*) exterior to the dark zone. These gases can easily be syphoned off by a piece of narrow gas tubing and burnt. This dark region (*b*) is comparatively cool. The highly luminous region is produced by incomplete combustion of the gases of the dark region; here hydrocarbons, rich in carbon, are produced, and burn with a luminous flame, and solid carbon separates and is raised to incandescence by the high temperature produced by the processes of combustion occurring in this region. In the outermost zone the combustion is practically completed, and this is the hottest part of the flame; a thin platinum wire introduced just within this region can be melted. A luminous gas flame is very similar to the candle flame just described. A non-luminous flame can be obtained by burning coal gas in two ways: (1) mixed with air or oxygen; (2) mixed with gases, such as nitrogen, carbon dioxide, hydrogen, etc. Hence it appears that non-luminosity is produced by the more complete combustion which occurs on burning coal gas mixed with oxygen, and also by the diluting action of inert gases. In the Bunsen flame or gas stove flame these two causes act together. The diluting gas nitrogen tends to lower the temperature of the flame; but the more complete combustion which goes on throughout the flame more than counterbalances the cooling effect of the nitrogen. In the Bunsen or gas stove flame there are only two parts: an inner dark or bluish part of unburned gas corresponding to the dark region (*b*) in the candle flame; an outer, nearly non-luminous part where combustion is complete. The heated gases of the inner region are capable of bringing about REDUCING REACTIONS; that is, of abstracting oxygen from metallic oxides, etc. The top of the outer region and the outer margin of it can effect OXIDISING ACTIONS, *e.g.* change a metal to its oxide. A blowpipe flame resembles a Bunsen flame. In the coal-gas flame the outer part, where combustion is most active, is positively electrified, while the inner part is negatively electrified. The gases escaping from nearly all flames are ionised, and thus have the power of discharging electrified bodies. When certain metallic oxides are brought into a hot, non-luminous flame, they become highly incandescent; *e.g.* the oxides of magnesium (MgO), aluminium (Al_2O_3), calcium (CaO), etc. The LIMELIGHT and the WELSBACH BURNER are applications of this fact: in the former the oxyhydrogen flame or the oxygen coal-gas flame is made to impinge on a cylinder of chalk or lime; in the latter case an ordinary non-luminous air-coal-gas flame is made to play upon a mantle composed of 99 per cent. of thorium oxide and 1 per cent. of cerium oxide. The nitrates of these metals in the proper proportions are dissolved, and a suitable fibre soaked in the solution; on burning away the fibre, a skeleton of the oxides remains.

Flame Plates (*Eng.*) The part of a firebox on which the flames of the fire impinge.

Flame, Sensitive (*Phys.*) A gas flame, when the pressure of the gas has been increased until the flame is on the point of flaring, is very sensitive to sounds, especially those whose pitch is very high. Such a flame is frequently used as a detector of high-pitched notes. The gas pressure should be about 8 in. of water, *i.e.* four times the ordinary pressure of the house supply of coal gas.

Flang (*Mining*). A Cornish name for a two-pointed pick.

Flange (*Eng., etc.*) A projection (usually with at least one plane surface) running round an object, *e.g.* the disclike projection at the end of a cast iron steam pipe, by means of which it is fixed to the adjoining length of pipe or the projection running along a girder (*q.v.*) The term is also applied generally to any continuous flat surfaced projection which is (usually) at right angles to the main surface of the object to which it is attached.

—— *or* **Flanged Chuck** (*Eng.*) A face plate, *i.e.* a broad, disc-like chuck whose plane surface is at right angles to the axis of rotation.

Flange Coupling (*Eng.*) A coupling or connector between two lengths of shafting, which consists of two castings resembling face plates with collars; each is keyed to the end of its piece of shafting, and the two are fastened together by bolts.

Flanged Beam *or* **Girder** (*Eng.*) A beam which in section is in the form of a letter I.

Flanged Nut (*Eng.*) A NUT (*q.v.*) with a flange resembling a WASHER (*q.v.*), but made in one piece with the nut. It is sometimes more convenient than a separate washer.

Flanged Pipe (*Eng.*) A pipe having a flange (*q.v.*) at the end by means of which it can be bolted to a similar pipe or seating.

Flanged Rail (*Eng.*) A rail with a flat flange at the bottom by which it is fastened down (*cf.* tramway rails); the ordinary form of rail now used on most kinds of permanent way is reversible, known as the DOUBLE HEADED RAIL, and has the same section at the top and bottom.

Flanged Seam (*Eng.*) A joint (made by two flanges) in a furnace tube, to allow of expansion and contraction during heating and cooling. The flanges are connected by a ring of wrought iron, often dished or corrugated.

Flanged Wheel (*Eng.*) A wheel with a flange round it, *e.g.* an ordinary locomotive or railway carriage wheel.

Flange Joint (*Eng., etc.*) Iron pipes having flanges at their ends for bolting together instead of spigot and socket.

Flanges on Cylinders (*Motor Cars, etc.*) Flanges are cast on the outside of the cylinders of small air cooled motors to increase the radiating surface and thereby aid in cooling the cylinder; they are usually termed RIBS *or* RADIATING RIBS.

Flanging (*Eng.*) The formation of a FLANGE (*q.v.*) by "up-setting" the end of a wrought iron tube by forging.

Flanks (*Build.*) The sides of a structure, especially of an arch (*q.v.*)

—— (*Eng.*) The lower part of the teeth of a spur wheel.

Flank Wall (*Build.*) A side wall.

Flannelette (*Textile Manufac.*) A fabric with a cotton warp and a woollen weft; also a fabric consisting entirely of cotton, both being made in imitation of woollen flannel.

Flap (*Carp.*) In general, a hinged board; *e.g.* the part of a counter that lifts up: a trap door.

Flap Trap (*Build.*) An iron flap on the sewer end of a drain.

Flap Valve (*Eng.*) A hinged valve; sometimes wholly or partly made of leather.

Flare Lard. A product obtained from the flare of a pig as opposed to the fat from the ham, breast, or back. It is characterised by the pronounced chisel shaped crystals of stearic acid which form on the evaporation of an ether solution, but which are scarcely distinguishable in soft lard.

Flare Lime (*Chem. Eng.*) Lime produced in a kiln out of contact with the solid fuel.

Flaser Structure (*Geol.*) A descriptive term applied to schistose rocks which were formerly massive, and have been sheared or drawn out by differential movements of the earth's crust during the earlier stages in the process of mountain making. The edges of the rock fragments thus sheared have a peculiar stringy look like the frayed out end of a cord. The structure may occur in rocks of any age, but is most commonly met with amongst those of great antiquity.

Flash Boiler (*Eng.*) A boiler in which water is instantaneously converted into steam by injection into tubes heated to a high temperature. Flash boilers are often used in steam motor cars, as they occupy little space. *See also* BOILERS.

Flashed Glass (*Dec.*) *See* GLASS MANUFACTURE and FLASHING (*infra*).

Flashing (*Build.*) Sheet lead or zinc, used to make a water-tight joint in the angle between a roof and a wall, or two parts of a roof meeting at an angle.

—— (*Glass Manufac.*) Casing or coating one glass with glass of a different colour.

Flashing Point *or* **Flash Point.** A term chiefly applied to mineral oils to indicate the temperature at which the oil, on being slowly heated, will give off inflammable vapour in sufficient quantity to "flash" or ignite on the application of a light. When the oil is further heated and continues burning, the temperature at which this commences is termed the "fire test." The methods employed for testing the flashing points of oils may be divided into two classes, *i.e.* the open test and the close test, which in this country are chiefly used for lubricating oils and illuminants respectively. In the former test the cup may be of any reasonable size, containing any convenient volume of oil, the "flash" being tested by passing a small jet of gas over the surface from time to time. In the latter the size of the cup, contents, rate of heating, size of gas jet, and frequency of testing for the "flash" are all precisely defined; and corrections have to be made for barometric pressure in relation to vapour tension. The standard instrument in this country is known as the ABEL CUP. Most countries have stringent laws as to the storage and sale of mineral oils based upon

what is considered the safe flashing point. In this country the Government minimum test for burning oils is 73° F. (*close test*), and applies essentially to imported oils, all the home production being well over 100° F. (Abel). The 73° F. standard is considerably lower than in most other countries, and efforts have frequently been made to raise it to 100° F. by legislation, but without success. The flashing point of other liquids besides mineral oil is sometimes of importance, as in the case of paints that are to be used in a confined space, such as a ship's cabin, where the accumulation of volatile materials given off by the special paints sometimes employed has given rise to serious accidents. Special official directions have recently been issued for testing such paints, metal polishes, etc.

Flask (*Chem., etc.*) A hollow vessel of thin glass, with a constriction or "neck" at the top. Flasks of many forms are very largely used in chemical and other experimental work.

—— (*Eng.*) The box in which sand is placed in the foundry to form a MOULD (*q.v.*) for the smaller sized castings. Flasks are made in two or more pieces which can be separated to enable the PATTERN (*q.v.*) to be withdrawn.

Flasques (*Her.*) A diminutive of FLANCHES; also called voiders.

Flat (*Build.*) A flat roof or part of a roof covered with lead, copper, or zinc.

—— (*Music*). A sign ♭ indicating that a note is to be lowered a semitone.

Flat Backs (*Bind.*) Whole bound or half bound books whose backs have the leather firmly glued or pasted to them. The style is nearly obsolete, except in the case of books subjected to great wear and tear, *e.g.* lending-library books. At present the leather is not usually connected to the back of the book; this prevents the back from creasing, and causes the book to open better.

Flat Joint (*Build.*) A mortar joint flush with the face of the wall.

—— **Jointed** (*Build.*) A flat joint with a groove made with a jointer (*q.v.*)

Flatness of Field (*Photo.*) A lens is said to give a flat field when the image of a distant object is equally in focus, whatever part of the screen it occupies. A small stop helps to correct want of flatness to a large extent.

Flatness of Image (*Photo.*) An image which is weak and wanting in vigour; usually an effect of over exposure or poor lighting.

Flats (*Eng.*) Iron bar of rectangular section, one side of the rectangle being considerably larger than the other. Still thinner bars are usually termed STRIP IRON.

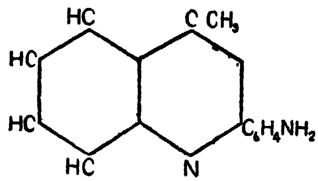
Flattener (*Glass Manufac.*) The workman whose duty it is to flatten cylinders into sheets. *See* GLASS MANUFACTURE.

Flatter (*Eng.*) A broad-faced tool used for producing flat surfaces in forging. It is held by a hammerlike handle and struck by a sledge hammer.

Flatting (*Dec.*) A method of finishing painted work without gloss. This is effected by omitting oil and thinning wholly with turpentine, a little varnish being added to bind the pigment together. As a rule the best results are obtained by using as a foundation a good glossy ground, and finishing with a coat of flatting.

Flaunching or **Flaunced Work** (*Build.*) The cement fillet round the bed of a chimney pot.

Flavaniline (*Chem.*)

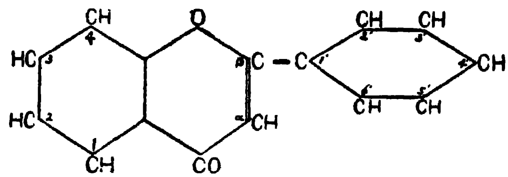


(α-para-amidophenyl-γ-methylquinoline). Colourless needles sparingly soluble in water, easily soluble in alcohol; melts at 97°. Obtained by heating acetanilide with zinc chloride, and by condensation of ortho- and para-amidoacetophenone. Its hydrochloride and its sulphonic acid were at one time used as greenish yellow dyes.

Flavanthrene. *See* DYES AND DYEING.

Flavine. *See* DYES AND DYEING.

Flavone (*Chem.*)

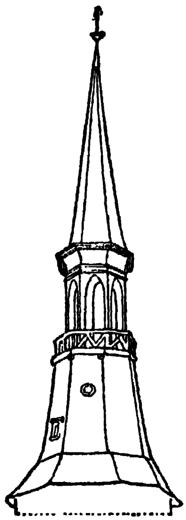


(β-phenyl-γ-benzopyrone). The stem or parent substance of a number of important naturally occurring substances, some of which are dyes. CHRYSIN is 1:3 dioxyflavone; forms *pale* yellow needles, and occurs in the buds of the poplar. APIGENIN is 1:3:4′ trioxyflavone, and occurs as a glucoside (apiin) in parsley and celery; it is also *pale* yellow. LUTEOLIN is 1:3:3′:4′ tetroxyflavone; is the colouring matter of Wald, an important beautiful yellow dyestuff. QUERCETIN is α:1:3:3′:4′ pentoxyflavone, and occurs as the glucoside quercitrin, which is found in the dye wood quercitrin bark, in tea, onions, horse chestnut, etc. It is a valuable yellow dye. FISETIN and MORIN are respectively α:3:3′:4′ tetroxyflavone and α:1:3:2′:4′ pentoxyflavone, and are the colouring matters of young fustic and old fustic.

Flavopurpurin. *See* DYES AND DYEING.

Flax. *Linum usitatissimum* (order, *Linaceæ*). The macerated bast fibres of the stem form the flax used in the manufacture of linen. The seeds are the well known LINSEED. The fibre of the flax plant has been used for manufacturing purposes since the time of the ancient Egyptians. From the botanical name "Linum" we get "lint" and "linen." The German name is "Flachs," and Dutch "Blasch." The fibrous portion is the inner bark, or rather lies between the bark and stem, surrounded by gummy matter, which is removed by "retting" (*q.v.*) *See* LINEN MANUFACTURE.

Flêche (*Architect.*) A wooden spire, usually situated on the ridge of a roof.



FLÊCHE.

Fled Ware (*Pot.*) Ware is described as fled when at any stage of its manufacture after the bisque firing it cracks spontaneously. This is generally caused by either too rapid heating or too rapid cooling at one or other of its burnings.

Fleece (*Woollen Manufac.*) A term applied to the wool when clipped from the sheep's back.

Fleece Wool (*Woollen Manufac.*) Wool grown subsequently to yearling.

Flemish Bond (*Build.*) Each course of bricks belonging to this class of bond consists of "headers" and "stretchers" placed alternately. Flemish Bond may either be single or double. In the former the wall is faced with bricks arranged in Flemish and backed with English bond, while in the latter both the facing and backing are Flemish.

Flemish School of Painting. *See* PAINTING, SCHOOLS OF.

Fleshing (*Leather Manufac.*) Removal of adhering flesh or fat from a skin previous to further treatment.

Flesh Side (*Eng.*) The side of a leather belt which formed the internal surface of the hide. This is the side which comes in contact with the pulley and driving wheel.

Flesh Split (*Leather Manufac.*) *See* BAG HIDES.

Fleur de Lis. The heraldic lily: a conventional flower emblem of France. The three lilies of France appeared on the Arms of England from 1299, when Edward I. married Margaret of Anjou, until 1801, when the union of Great Britain and Ireland took place.

Fleurettée *or* **Florettée** (*Her.*) Ending in fleur de lis.

Fleurie (*Her.*) Ending in three points.

Fleuss Pump. *See* AIR PUMPS.

Fleuss Tyre (*Cycle*). *See* TYRES.

Flexed (*Her.*) Curved or bowed.

Flexible (*Bind.*) Applied (*a*) to small Prayer books, Bibles, etc., sewn with silk to silk cords; and (*b*) to music, etc., bound without sewing, the backs of the leaves being cemented together with an india-rubber solution, thus ensuring good flat opening.

Flexible Coupling (*Eng.*) A coupling (*q.v.*) which enables two shafts not in the same straight line to be connected so as to turn together. It usually consists of a ball and socket joint; but a HOOKE'S JOINT (*q.v.*) is sometimes used.

Flexible Shafting. *See* SHAFTING, FLEXIBLE.

Flexible Tubing. *See* TUBING, FLEXIBLE.

Flexure *or* **Bending.** The bending of a beam is measured either by the deflection of a given point in it from a straight line, or by the curvature which it acquires under the action of the load.

Flier (*Joinery*). A step parallel in its width. *Cf.* BALANCED STEPS *and* DIMINISHED FLIER.

Flight (*Build.*) A number of consecutive steps between a floor and landing.

Flints (*Geol.*) Nodular concretionary masses of impure chalcedony, which represent what was formerly silica of organic origin dispersed throughout its matrix. The most familiar examples in Britain occur in the Chalks; but flints are of common occurrence in other limestones, even of Tertiary age. Much of the silica under notice was formerly part of the organic structure of sponges. The silica has been dissolved by percolating water, and redeposited around some organic nucleus at a lower level. It is frequently formed by replacement of its matrix.

Flint Ware (*Pot.*) The name applied in the United States to stone ware.

Flitch (*Eng., Build., etc.*) A piece of metal or wood fixed to a beam, etc., to add to its strength.

Flitch Beam *or* **Flitched Beam** (*Eng., Build., etc.*) A wooden beam built up round a core, plate, or central piece of wrought iron, the whole being held together by bolts. *See also* FLOORS.

Flitch Plate (*Eng., Build., etc.*) A flitch (*q.v.*)

Float (*Eng., etc.*) A floating object (wood or a thin hollow vessel of metal) which is used to indicate the level of water, etc., in a boiler or tank. It usually actuates some form of dial or pointer, on which divisions representing the level of the liquid are marked.

—— (*Motor Cars*). A hollow vessel, usually of thin sheet metal, which floats on the surface of the motor spirit in one of the chambers of a carburetter (*q.v.*), and by rising and falling with the variations in depth of the spirit, acts on a valve and controls the supply. *See also* SPRAY CARBURETTER.

—— (*Plast.*) A flat rectangular plate of steel, with a handle fixed on one side, used for smoothing flat surfaces of plaster.

—— (*Textile Manufac.*) A defect in weaving which gives an irregular appearance to the cloth. Also a term used in designing to denote the number of ends or picks a thread passes over, *i.e.* four pick float, etc.

—— *or* **Float Cut File** (*Eng.*) A file with only one series of teeth, which do not cross, as in the ordinary file. *See* FILE.

Floated (*Build.*) The surface of plaster which has been finished with a float.

Floating Bridges (*Civil Eng.*) Bridges carried by boats or pontoons (*q.v.*), used for temporary purposes, or in cases where openings have to be made for the passage of vessels, or where a good foundation cannot be obtained. One of the best examples is at Calcutta; this bridge is 1,530 ft. long and 48 ft. wide, and is carried on twenty-eight iron pontoons. The bed of the river Hugli is so loose and the current so rapid that permanent foundations are not practicable in this case.

Floating Card Compass. A magnetic needle to which is fixed a card, which turns with the needle. The card is divided into degrees; a line on the card marked N and S points due north, *i.e.* makes an angle with the needle equal to the magnetic declination (*q.v.*) at the place where the compass is to

be used. Thus, instead of reading the deflection of the needle relative to the card, as in an ordinary compass, the deflection of the card relative to a fixed mark on the inside of the case of the instrument is read.

Floating Mill Wheel. An undershot wheel carried by a boat or raft and actuated by the current of a river in which it is moored: a contrivance not often used.

Floating Reef (*Mining*). Loose masses of ore disconnected from the principal vein.

Floating Vessel (*Glass Manufac.*) This is made of fireclay, and consists of two or three compartments. Used in tank furnaces for refining the metal. The molten glass enters at a depth below the surface of the metal in the tank, and is withdrawn therefrom by the gatherer.

Floats *or* **Float Boards** (*Eng.*) The vanes or paddles of a paddle wheel or undershot (*q.v.*) water wheel.

Float Stone (*Min.*) A porous variety of silica containing so much air that a piece will float on water. Found near Paris.

Flock Paper (*Dec.*) A wallpaper with a raised surface, formed by printing the pattern with gum or other adhesive material and dusting on fine shreds of plain or coloured wool. In "silk flocks" the wool is replaced by silk shreds. Flock papers are not now used to any considerable extent.

Flogging (*Eng.*, *Carp.*, *etc.*) A term for the removal of the rough surface or of large pieces of wood, metal, etc., while the piece of material is being cut approximately to shape.

Flogging Chisel (*Eng.*) A large cold chisel occasionally used in heavy cutting.

Flong (*Stereotyping*). Flong is used in the *papier-maché* process of stereotyping. It is composed of a number of layers of tissue and blotting papers used alternately, with paste or composition between. In a plastic state it is placed upon the form, and its surface beaten until an impress of the face of the type is obtained. When hardened, it becomes the mould from which a stereotype plate is produced.

Flood (*Meteorol.*) Owing to excessive rainfall, rivers, lakes, ponds cannot be restricted to their banks, and the overflowing of the water causes floods in the regions around.

Flookan *or* **Flucan** (*Mining*). A vein containing a great deal of clay.

Floor (*Foundry*). The sand bed which forms the floor of a foundry; it serves as a reservoir of rough sand, and also as the receptacle for large moulds in making heavy castings.

Floor Cramp. A cramp for squeezing floor boards together whilst being nailed.

Floors. The simplest kind of floor is that known as a SINGLE FLOOR (fig. 1). This is used in cases where the span is not more than 15 or 16 ft. It consists of a number of COMMON or BRIDGING JOISTS AAA, whose ends rest on a WALL PLATE B, which rests either on an OFFSET or ledge as shown, or on corbels (*q.v.*) specially built to carry it. On the top of the joists are nailed the FLOOR BOARDS CCC. The joists are usually from 8 to 11 in. deep, and are set about 1 ft. apart. The laths which carry the ceiling below the floor are either nailed to the joists or else to small CEILING JOISTS DD. When the span is large, common joists would not be sufficiently strong to be used alone; in this case heavier timbers are used to support the ends of the common

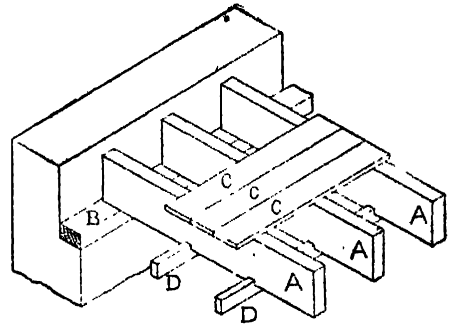


FIG. 1.—SINGLE FLOOR.

joists at convenient positions: the combination is then termed a DOUBLE FLOOR (fig. 2). The joists AA rest on the larger timbers or BINDERS, one of which is shown at EE. The binder may be notched, as shown at F, or the notch may be made in the joist only, which is the preferable method, as it does not

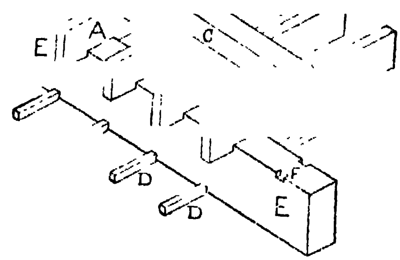

FIG. 2.—DOUBLE FLOOR.

weaken the binder. A double floor usually has ceiling joists DD, which are often fixed to the binders by means of a CHASE MORTICE, a mortice into which the tenon can be inserted by sliding it along a groove or CHASE. For very large spans a double floor is superseded by a DOUBLE FRAMED FLOOR (fig. 3 and

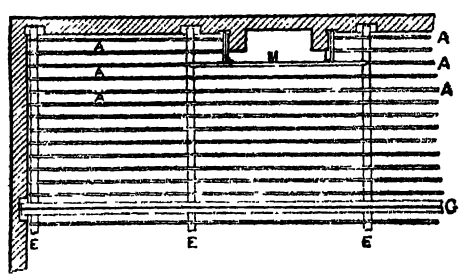

FIG. 3.—DOUBLE FRAMED FLOOR.

fig. 4). AAA are common joists resting on binders EEE: The binders are supported by a GIRDER G. In fig. 4 is shown a cross section of a FLITCH GIRDER, consisting of two half-timbers HH placed with the

heart-wood outwards and strengthened by an iron plate K, termed a FLITCH PLATE, the whole being secured by bolts which fasten the timbers and iron plate together. The binders may be morticed into the girder by means of a TUSK TENON (*q.v.*), or may be supported by an iron stirrup or bracket which rests on the girder. The latter method is preferable, as the strength of the girder is not diminished by cutting a mortice in the material. When an opening has to be made in a floor, *e.g.* round a staircase or fireplace, the joists are TRIMMED, *i.e.* supported by

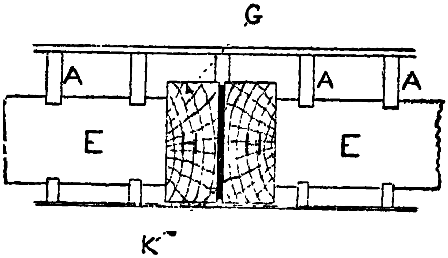

FIG. 4.—DOUBLE FRAMED FLOOR

intermediate timbers, as shown in fig. 3. These timbers or TRIMMERS are shown at LL. The joist M is termed a TRIMMING JOIST, and is made of greater thickness than the common joists, in order to enable it to carry the extra load thrown upon it. In fig. 3 it will be seen that the ends of binders and girders alike are carried in openings or POCKETS in the wall, and are not built in. The timber rests on a stone base or template, and the top of the pocket or opening may be formed by a single stone or by a small arch, so as to allow a free play of air round the end of the timber.

Floor Space (*Hygiene*). To deal effectually with the problem of maintaining the air of rooms in a pure condition, an adequate allowance of floor space is essential. At the lowest it should not be less than one-twelfth of the cubic space. Set out below will be found a minimum floor space for different institutions:

Tents and vans .	16	sq. ft.	for each adult male.
Schools . . .	10	,,	per scholar (elder).
,, ...	8	,,	,, (infant).
Artizans' dwellings	150	,,	in living room.
,, ,,	120	,,	,, bedroom (adults).
,, ,,	80	,,	,, ,, (children).
Hospitals . .	120	,,	per bed.

It is of great importance that a good floor space should be provided per bed in hospitals, to ensure a supply of pure air, and for facilities for nursing.

Floran (*Mining*). Fine tin ore.

Florentine Mosaic. Mosaic work formed by inlaying small surfaces of marble with precious stones, such as chalcedony, etc.

Florentine School of Painting. *See* PAINTING, SCHOOLS OF.

Florid Gothic (*Architect.*) *See* PERPENDICULAR *and* TUDOR.

Flos Ferri (*Min.*) A variety of aragonite (*q.v.*) occurring in coralloidal masses, usually of a white or faint brown colour. The name is derived from its association with iron (in the mines of Styria). Other localities are Silvera Band Mine, near Milburn, and Rundale Mines, near Dufton, in Westmoreland, and the mines of Wanlockhead, in Dumfriesshire.

Flour (*Foods*). The term flour, without any modification, generally means wheat flour. This is divided into two groups—white wheat and dark wheat. The colour in the latter case is due to the presence of bran. A good flour should be quite white, and not gritty or lumpy. It should not taste acid, although when tested with paper (litmus) the reaction should be slightly acid. Flour is adulterated by (*a*) the flour of other grains and (*b*) mineral substances. In the first section we have barley, maize, peas, rice, oats, etc.; and in the second, alum, gypsum, carbonate of magnesia, carbonate of calcium, etc. Detection of these adulterants is obtained by microscopic and chemical examination. *See also* BREAD.

Flouring (*Met.*) The spoiling of the mercury used in gold extraction by absorption of impurities from the ore.

Flow *or* **Flow Pipe.** The pipe by which the water leaves a boiler. Used to heat a building, etc.

Flowers of Sulphur. Finely divided sulphur, obtained by sublimation (*q.v.*)

Flowing Tracery (*Architect.*) *See* CURVILINEAR *and* DECORATED.

Flue (*Eng.*, *Build.*, *etc.*) A general term for a passage through which smoke, etc., escape from a furnace or fire. In boilers the flues are commonly utilised as part of the heating surface. *See* BOILERS.

Flue Bridge (*Eng.*) A barrier of firebrick placed so as to deflect the flames and hot gases in a furnace.

Flue Work (*Music*). All organ stops not belonging to the Reed family. Flue work is subdivided into: (1) Principal work, (2) Flute work, (3) Gedact work.

Fluffing (*Leather Manufac.*) The process of rubbing the skin on a revolving emery wheel to fluff it, *i.e.* make it smooth.

Fluffy (*Carp.*) Timber which cuts up in a "stringy" manner.

Fluid. A fluid is a substance which is unable to resist the action of any force (however small) which tends to change its shape. *See* LIQUID *and* GAS.

Fluidity. The property of flowing easily and readily: the opposite of viscosity.

Fluid Ounce. *See* WEIGHTS AND MEASURES.

Fluke (*Mining*). A rod used to clear out holes which have been drilled to receive a charge for blasting.

Flume (*Eng.*, *Mining*, *etc.*) A channel (usually open at the top) for carrying water, *e.g.* to a mill-wheel, etc.

Fluorene (*Chem.*) $\begin{matrix} C_6H_4 \\ | \\ C_6H_4 \end{matrix}\!\!\Big> CH_2$ (diphenylenemethane). Colourless needles showing a violet fluorescence; melts at 113° C. It occurs in that fraction of coal tar which distils from 300 to 305° C. It is formed by passing the vapour of diphenylmethane through a redhot tube. BIFLUORENE (bidiphenylene ethylene) $\begin{matrix} C_6H_4 \\ | \\ C_6H_4 \end{matrix}\!\!\Big> C : C \Big<\!\!\begin{matrix} C_6H_4 \\ | \\ C_6H_4 \end{matrix}$, formed when fluorene is heated with bromine, is remarkable as being a

coloured hydrocarbon; it crystallises in beautiful red needles.

Fluorescein (*Chem.*) 
Dark yellow crystalline solid; insoluble in water; soluble in glacial acetic acid. Obtained by heating resorcin (*q.v.*) with phthalic anhydride (*q.v.*), alone or with sulphuric acid or zinc chloride. It dissolves readily in alkalis, forming a salt, and the solution has a yellowish brown colour, with a magnificent green fluorescence. It is used as a dye. *See* EOSIN *and* ERYTHROSIN.

Fluorescence. A number of substances, when illuminated by light of certain wave length, emit light of greater wave length (and therefore of different colour). This property is termed FLUORESCENCE, and is possessed by fluorspar (from which the name is derived), certain organic compounds, *e.g.* eosin, quinine, fluorescein, and also by a number of salts.

Fluorides (*Chem.*) Salts of HYDROFLUORIC ACID (*q.v.*)

Fluorine, F. *Atomic weight*, 19. A gas similar to, but lighter in colour than, chlorine. Has a powerful and irritating odour; is liquefied about $-185°$, forming a yellowish liquid. It is obtained by electrolysis of hydrofluoric acid, to which a little potassium hydrogen fluoride has been added. Platinum or copper vessels must be used throughout. *It is the most reactive element known.* Unites with hydrogen with explosion. Most other elements burn in it, forming fluorides; but oxygen and nitrogen do not combine with it. Glass is instantly decomposed by it. Silica becomes redhot in it, and organic compounds are immediately decomposed. In all cases fluorides are formed. Liquid fluorine is less active; it does not attack glass. Gaseous fluorine passed into liquid oxygen forms a white flocculent precipitate, which deflagrates violently when its temperature rises.

Fluorspar (*Min.*) Calcium fluoride, CaF_2. Calcium = 51·3, fluorine = 48·7 per cent. Cubic; in crystals of a great diversity of colour, most commonly blue, green, or yellow. It exhibits fluorescence and phosphorescence when heated. With sulphuric acid gives off fumes of hydrofluoric acid, in the manufacture of which it is used. Sometimes used as a flux. The massive varieties are used as ornamental stones. From Alston Moor, Derbyshire, Cornwall, the Harz, Bohemia, many parts of North America, etc.

Flush (*Eng.*) At the same level; forming part of the same surface.

—— (*Hygiene*). The water that flushes out a closet pan, etc.

Flushing (*Eng., etc.*) Clearing out a space by passing a quantity of water or air through it. Drains are flushed by clean water. A gas engine cylinder is sometimes flushed or cleared of the products of combustion by driving a quantity of pure air through it. The valves of automobile motors are "flushed" with spirit to wash grit or deposit from the seatings.

Flush Joint (*Build.*) *See* FLAT JOINT.

Flush Panel (*Carp.*) A panel that is level with the framing; *i.e.* one whose surface lies in the same plane as that of the framing.

Flush Tanks, Automatic (*Hygiene*). It is not always possible to give the sewers and drains sufficient fall to make them self-cleansing. Under these circumstances the normal flow of sewage should be supplemented by automatic flush tanks. They should be placed at the head of the drain, and made to discharge at whatever intervals are found necessary. Of the many forms on the market, Field's flush tank (*q.v.*) takes the highest place. The use of these tanks is also of considerable value in schools, public buildings, and châlets.

Flute. *See* MUSICAL INSTRUMENTS: WIND (WOOD).

Flutes (*Architect.*) The vertical hollows formed in the shafts of classical columns and pilasters, either with or without fillets. *See* ARCHITECTURE, ORDERS OF; CABLE.

—— (*Carp.*) The cylindrical sinkings cut in a column, bracket, or pilaster.

—— (*Glass Manufac.*) The furrows in rolled plate glass.

Flute Work (*Music*). The flue stops of an organ not belonging to the principal or gedact work.

Fluting (*Eng., etc.*) Parallel grooves, of any form of cross section, in an object. They may be merely ornamental or may serve some useful purpose, as in a REAMER (*q.v.*), in which they often form cutting edges.

Flux (*Elect.*) The total number of lines of force which pass through any given space or cross any given area.

—— (*Met., Chem.*) A substance used to facilitate the fusion and subsequent separation of impurities in metallurgical and soldering operations. Thus in the blast furnace, when clay ironstone is the ore, limestone is added to form a fusible slag of a double calcium and aluminium silicate which is easily separated from the iron. In welding iron, sand, which is an easily fusible silicate of iron, is used as a flux to remove the oxide of iron; in brazing, borax is used as a flux because it easily dissolves metallic oxides. Resin, sal-ammonia, and "killed spirits" (zinc chloride) are used in soldering. BLACK FLUX, often used in blowpipe operations, is a mixture of potassium carbonate and carbon.

—— (*Pottery*). A material composed of agents that will melt at a comparatively low temperature, such as alkaline salts, in combination with silica, lime, or lead. It is used in the formation of glazes and enamel colours. In the form of lime it gives translucency to porcelain.

Flux Density (*Elect.*) The FLUX (*q.v.*) per unit area, *i.e.* the number of lines of force which pass through a unit area placed at right angles to the lines.

Fly (*Clocks*). A fan used to control the speed of a running train of wheels, as in the striking trains of a clock. It is usually a rectangular sheet of thin metal, fitted spring tight on its pinion in house clocks, or with a ratchet and click in turret clocks, so that it may continue to move until its energy is expended and without injury to the mechanism of the clock, after the pinion has been arrested and the train locked. *See* RATCHET *and* TRAIN.

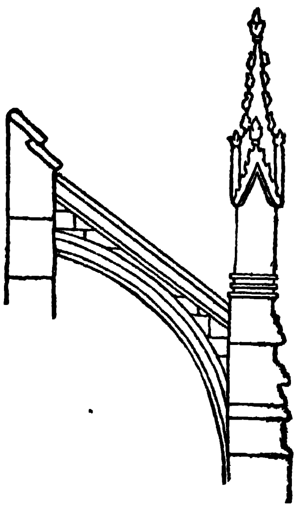
Fly (*Woollen Manufac.*) The fibre given off various rollers in carding (*q.v.*); also applied to the FANCY (*q.v.*)

Fly Batten (*Silk Manufac.*) *See* BATTEN.

Fly Cutters (*Eng.*) Revolving cutting wheels, such as are used in a milling machine, for shaping small objects to a special form.

Fly Frames (*Cotton Manufac.*) A general term applied to slubbing, intermediate, roving, and jack frames. Sometimes also termed speed frames.

Flying Buttress (*Architect.*) A form of buttress frequently used in Gothic churches to take the thrust of the nave vault. It consists of a vertical buttress placed on the external wall of the aisle and connected to the nave wall by means of an arch.



FLYING BUTTRESS, SALISBURY CATHEDRAL.

Flying Shore (*Build.*) A horizontal shore.

Fly Leaf (*Bind.*) *See* END PAPERS.

Fly Nut (*Eng., etc.*) A nut with wings to enable it to be turned by thumb and fingers.

Fly of a Flag. The length that it extends from the staff measured along the edge. The measurement along the edge parallel to the staff is termed the "Dip."

Fly Press (*Eng.. etc.*) A press in which a die is driven by a screw working vertically through a fixed nut, the screw carrying heavy loaded arms.

Fly Shuttle (*Textile Manufac.*) The method of picking (*q.v.*) invented by John Kay.

Flywheel (*Eng.*) A heavy rotating wheel. It serves as a store of energy, and helps to maintain a steady rate of rotation of the shaft of the engine or other machinery to which it belongs. The size of a flywheel, or more exactly its MOMENT OF INERTIA (*q.v.*), is determined by the normal speed of the engine and by the fluctuations of speed which are permissible. An engine which is required to run very steadily, *i.e.* with very small fluctuations of speed, as in the case of an engine driving a dynamo, requires a heavier flywheel than one where variations in speed are of small importance.

F.O.B. Free on board: applied to goods which the seller undertakes to deliver on board ship without any charge for carriage or loading.

Focal Length of a Lens (*Phys.*) The true focal length of a lens is the distance from the principal focus (*q.v.*) to the nearest principal point (*q.v.*) In the case of a thin lens it is sufficiently accurate to measure the distance from the surface of the lens itself to the principal focus.

Focal Planes of a Lens (*Phys.*) A pair of planes drawn through the PRINCIPAL FOCI (*q.v.*) of a lens at right angles to the axis.

Focus (*Phys.*) The point towards which rays converge or from which they appear to diverge.

——, **Principal** (*Phys.*) A pencil of parallel rays of light after incidence on a mirror or lens is caused to converge towards a single point or to appear to diverge from a single point. This point is called the PRINCIPAL FOCUS of the mirror or lens. In the second case the principal focus is VIRTUAL, in the first case it is REAL.

Focussing. The adjustment of the position of certain parts of an optical instrument, *e.g.* the eyepiece of a telescope or microscope, or the lens of a camera or lantern, in order to obtain a clearly defined image.

Focussing Lens (*Lantern*). In lantern work the objective is often so termed. *See* LANTERN OBJECTIVE.

—— (*Photo.*) A magnifying glass by means of which the image on the ground glass screen of a camera is examined, in order to obtain the most exact position in focussing.

Foehn Winds (*Meteorol.*) The name for warm, dry winds or hot waves peculiar to some mountainous regions, as the Alps in Switzerland.

Fog (*Photo.*) A general name for a darkening of parts of an image, usually through the improper action of light; occasionally "chemical fog" is produced by some fault in the composition of the solutions used. *See* GREEN FOG, RED FOG, GENERAL FOG.

—— (*Meteorol.*) When air is cooled just below dew point, then fog, mist, or cloud occurs. Dust particles in the air accelerate the formation of fog; hence the frequency of fogs in large cities due to the small particles in smoke.

Fogbow (*Meteorol.*) A colourless or "white" rainbow occasionally formed on a mass of thick fog.

Fog Image (*Meteorol.*) The shadow of an observer cast on a fog or cloud bank by the sun.

Foils (*Architect.*) The leaf shaped spaces between the cusps used in Gothic tracery. *See* CUSP, TREFOIL, QUATREFOIL, CINQUEFOIL, *and* MULTIFOIL.

Fold (*Woollen Manufac.*) The term applied to yarns composed of two or more threads.

Folded Yarns (*Cotton Manufac.*) *See* DOUBLING.

Folding Doors (*Joinery*). A pair of doors with rabbeted (rebated) meeting styles.

Foliated Structure (*Geol.*) Rocks which have been sheared under great pressure deep within the Earth's crust during the earlier stages of mountain making nearly always show a banded arrangement of their constituents. Thus bands of felspar may alternate with others of mica, hornblende, or other minerals, and impart to the rock a pseudo-stratified appearance, which needs to be distinguished in some way. All gneisses and most schists are foliated rocks. The structure is due, in some cases, to chemical changes which have taken place during the shearing process.

Folklore Weather (*Meteorol.*) A saying with reference to approaching weather as foreshadowed by certain atmospheric conditions on objects animate and inanimate.

Follicle (*Botany*). A dry dehiscent fruit resembling the pod, but opening on one side only. Aggregations of these fruits are seen in the columbine, monkshood, etc.

Follicle (*Zool.*) A small saclike cavity or receptacle; *e.g.* the small pit in which the root of a hair is contained, or the structure which surrounds an OVUM (*q.v.*)

Follower (*Eng.*) A toothed wheel which is driven by another wheel, termed the DRIVER.

Fontainebleau Limestone (*Geol.*) A variety of calcite containing a large admixture of sand. From Fontainebleau in France. The percentage of sand may be as high as 80 per cent.

Food, Adulteration of (*Hygiene*). *See* ADULTERATION OF FOOD.

Foods (*Hygiene*). All food constituents may be classified as (1) nitrogenous, (2) fats, (3) carbohydrates, (4) salts, (5) water. (1) Nitrogenous foods include the albumens, and are necessary for the nutrition and repair of the tissues. Urea and uric acid produced in the system from nitrogenous foods are eliminated by the kidneys. When these are taken in excess it leads to a gouty condition. If too little nitrogenous food is taken, debility and loss of energy is produced. (2 and 3) Fats and carbohydrates, or starches and sugar, are necessary for the production of force and heat, and are eliminated from the body as CO_2 and water. The amount of these taken should depend on the amount of work done. If a large amount of muscular exercise is taken, there is a correspondingly great increase in the elimination of CO_2 and water. The starches and sugars are more easily eliminated than fats, but have not the same nutritive value. (4) The salts required for growth and nutrition are lime, potash, soda, and small quantities of iron. Phosphates, chlorides, and the nitrates and citrates of organic acids are also necessary. (5) Water in considerable quantity is also required, as it is contained in all the tissues of which the body is composed. The amount of nitrogenous food, fat, carbohydrates, and salts necessary per diem for an average man varies according to the amount of work done, but the following table (according to Whitlegge) may be given as a guide:

	Nitrogenous.	Fat.	Carbohydrates.	Salts.	Containing	
					Nitrogen.	Carbon
Rest . .	3 oz.	1½ oz.		1 oz.	200 gr.	4,000 gr.
Moderate work .	4½ ,,	[illegible] ,,	[illegible]		300	5,000 ,,
Hard work	6 ,,	4½ ,,	18		400	6,000 ,,

The following figures may be taken as the average of the above, and can be remembered readily: Nitrogenous, 5 oz.; fat, 3 oz.; carbohydrates, 15 oz.; and salts, 1 oz.; containing 350 gr. nitrogen and 5,000 gr. carbon. The above amounts are calculated free from water, and as most foods contain water, the actual weight in food stuffs will be nearly 50 oz. To this has to be added a further 40 to 50 oz. of water, which is necessary for digestion and assimilation of the food, as well as for the removal of effete products. Tables have been constructed showing the amount of water, albumen, fats, carbohydrates, and salts occurring in the chief articles of diet, and from these, by simple equations, the amount of each article of food necessary can be readily calculated. For example, how much bread, butter, and milk will be required to make up the average amount of albumen, fat, and carbohydrates? Bread contains 8 per cent. of albumen and 50 per cent. of carbohydrates; milk contains 4 per cent. albumen, 3 per cent. fat, and 4·5 per cent. carbohydrates; and butter contains about 80 per cent. pure fat. Let x be the amount of bread, y the amount of milk, and z the amount of butter required, then

$$\frac{8x + 4y}{100} = 5, \quad \frac{3y + 80z}{100} = 3, \quad \frac{50x + 5y}{100} = 15.$$

Working out these equations, we find that the amount of bread required is about 22 oz.; butter, ·7 of an oz.; and milk, 81 oz. A more complete dietary can be worked in the same way if the percentage composition of the foods selected be known. The quantity of food, and consequently the amount of the proximate constituents will necessarily vary according to the age, sex, and the work at which the individual is engaged. Besides being sufficient in amount, there must be a certain variety in the food taken. It must also be palatable, and for this purpose the various condiments are necessary. The food must likewise be of good quality, and the legislature has given powers to local authorities in the Public Health Acts to see that all foods exposed for sale or deposited in any place for the purpose of sale are fit for human food. Cattle are subject to certain specific diseases which render their flesh not only unfit for food, but also dangerous. The chief diseases are pleuropneumonia, cattle plague, anthrax, foot and mouth disease, glanders, farcy, and tuberculosis; in pigs, hog cholera, measles, trichinosis; and in sheep, rot due to the presence of small animals called "flukes" in the bile ducts of the liver. Good beef should be firm to the touch, of bright red colour, with a moderate amount of juice, and the fat should be white and hard. There should be no odour, and to test this a skewer can be thrust into the meat and smelt after being withdrawn. If there is any disagreeable smell, the meat should not be used, as this shows that putrefaction is commencing. The flesh of poultry should be whitish pink and firm, and the smell fresh. A slight bluish discolouration over the breast bone shows that the fowl has not been recently killed, but the flesh is not on that account unwholesome. If, however, on opening the bird, the smell is offensive, the flesh should not be eaten. With regard to game, this is not usually eaten till it is "high," this meaning that some decomposition has set in. Fish should be firm to the touch, and the smell should be fresh. Decomposition sets in very quickly in fish, and any staleness can be readily detected on opening them. Tinned meat is, as a rule, wholesome; but sometimes it may give rise to serious symptoms of poisoning due to the production of alkaloids called ptomaines. These may be produced in meat, pork, ham, or sausages, and it is frequently impossible to tell whether there are any present by simply looking at the articles. Sometimes, however, in the case of tinned foods, the tin is what is called "blown"; that is, the sides are blown out instead of being sunk in, this being due to putrefactive changes. Poisoning may take place also if the meat has absorbed any of the lead or tin, and this holds good also of tinned fruits. Bread is, as a rule, of very good quality, and the adulteration with alum which used to be practised has been given up. The only adulterant now employed, if it can be so called, is potatoes. If no bran is used, then the bread should be white in colour, and it should be free from acidity. *See* BREAD. Milk should be opaque and *fine white in colour*, and should on analysis give at least 3 per cent. of fat, 8·5 per cent. of solids not fat, and have a specific gravity of about 1,030. There should be no deposits either before or after boiling. As milk is the principal food of infants and young children, great care should be taken in regard to it. For

young children the milk should at once be boiled when delivered, and then placed in a thoroughly clean bottle or other closed receptacle in a cool place. If placed in large bowls, these ought to be covered so as to prevent contamination by means of flies or dust. No article of food is so susceptible of contamination, and if greater care were taken in the preservation and storage of milk in our houses there would be a great diminution in the infantile mortality from diseases of the digestive organs. *Preservatives should never be added to milk.* Nevertheless, occasionally salicylic acid, formalin, or boric acid are added by vendors to prevent it from turning sour. The souring of milk is due to the conversion of the sugar into lactic acid, which latter coagulates the casein, causing the milk to curdle. Colouring matter—*e.g.* annatto—is used to give it a richer colour, but this, though not injurious, is quite unnecessary. Water is the most common adulterant, but recently separated milk, or milk cleared of all its fat, is added, seriously affecting the nutritive value. Butter is a very commonly used food. It differs from margarine in that it is derived from milk, while margarine is derived from the fat of animals. There is little or no difference in the nutritive value, but butter fat is more readily assimilated. Tea is not at present adulterated, but coffee is frequently adulterated with chicory.

Foot. *See* WEIGHTS AND MEASURES.

Foot Block (*Carp.*) The flat piece of timber at the foot of a raking shore. *See* SHORES.

Foot Blower (*Glass Manufac.*) The glassmaker who gathers the metal and also makes the feet for wine glasses, etc. The third man in a set or "chair" of workmen (flint glass trade).

Foot Brake (*Motor Cars, etc.*) A brake applied by a lever or treadle which the driver actuates with his foot.

Footings (*Build.*) The projecting courses at the bottom of a wall.

Foot Pound (*Eng., Phys., etc.*) The English engineer's unit of work; the amount of work required to be expended in order to raise 1 lb. through a vertical height of 1 ft.

Foot Rests (*Cycles*). Small brackets on the front forks; rarely employed in ordinary cycles now that free wheels are usually fitted. In motor cycles foot rests are commonly fitted in a convenient position near the pedals.

Foots. A general term applied to the impure residue left in refining oils, fats, waxes and greases, such as cotton and linseed oils, spermaceti, Yorkshire grease. They are usually of very complex composition. Linseed oil foots contain a quantity of mucilage mixed with the oil, and are often used in making putty (*q.v.*) Cotton oil and grease foots are worked up in soap making.

Footstep Bearing (*Eng.*) A bearing (*q.v.*) which supports the lower end of a vertical shaft.

Foot Ton. The amount of work necessary to raise 1 ton 1 ft. high; it is equal to 2,240 ft. lbs.

Foot Valve (*Eng., etc.*) The valve at the bottom of a pump barrel or at the bottom of the suction pipe.

Footwall (*Mining*). The under or lower side of a vein or lode.

Footway (*Mining*). Ladders leading down a shaft, by means of which an ascent or descent may be made when the winding gear is not in operation.

F.O.R. Free on rail. *Cf.* F.O.B.

Foramen Magnum (*Zool.*) The large opening at the back of the skull through which passes the MEDULLA OBLONGATA (*q.v.*) of the central nervous system.

Foraminifera (*Zool.*) One of the divisions of the *Protozoa* (the simplest animals). The foraminifera possess a shell which is usually calcareous (composed of salts of calcium). The majority are marine, and are found at all depths. Their shells occur as fossils in rocks from Silurian age onward, and form the bulk of most kinds of chalk.

Force (*Phys., Mech., etc.*) Force is that which changes (or tends to change) the state of rest or motion of a body. It is also defined as "that which moves (or tends to move) matter."

Forced Draught (*Eng.*) An air supply driven through the fires of a boiler, etc., by means of fans or pumps, but principally by steam injectors, instead of the natural air current which is produced by the rush of hot air up the chimney or funnel. It is used when the boilers are being worked at a high power, *i.e.* when they are required to produce more than the usual amount of steam, as in the case of ships which are running at their highest possible speed.

Forced Draught Furnace (*Eng.*) The forced draught furnace, by which air and steam are supplied under pressure from steam jet injectors into a closed grate, has been very widely applied in late years to the combustion of inferior fuels (such as duff, breeze, pond, settlings, and washery refuse) and town's refuse, for the generation of steam and electric power. This system has almost revolutionised the working of destructors and assisted many manufacturing operations by obtaining steam power from waste products.

Forced Vibrations (*Phys.*) Vibrations produced in a body (or system of bodies) by a force periodically applied at intervals of time, which are not the same as the period of the natural vibrations. Thus a pendulum may be made to execute forced vibrations if it be struck intermittently, or if the point of suspension be moved to and fro at intervals different from the natural period of the pendulum.

Force, Lines of (*Elect.*) *See* LINES OF FORCE.

——, Moment of (*Phys.*) *See* MOMENT OF FORCE.

Force Piece (*Mining*). Diagonal struts across a working.

Force Pump (*Eng.*) A pump in which the water is driven upwards by the pressure of a solid piston (*i.e.* one without valves). The height to which the water can be raised is independent of atmospheric pressure (which limits the height reached in the suction pump), and depends only on the power applied and the strength of the pump and pipes. *See also* PUMPS.

—— (*Plumb. and Gas Fitting*). An air pump for cleaning out service pipes.

Forces, Composition of (*Mech.*) The calculation of the RESULTANT (*q.v.*) of two or more forces.

——, Moment of (*Mech.*) The moment of a force about a given point is the product of the amount of

the force into its perpendicular distance from the point.

Forces, Parallelogram of (*Mech.*) If two forces acting at a point be represented in magnitude and direction by the sides of a parallelogram, then the RESULTANT (*q.v.*) of the two forces is similarly represented by the diagonal of the parallelogram.

——, **Polygon of.** Any number of forces in equilibrium, acting at a point, may be represented in magnitude and direction by the sides of a completely closed polygon, taken in order. *See also* GRAPHIC STATICS.

——, **Resolution of** (*Mech.*) Any force may in general be replaced by two or more forces, which, when acting together, produce the same effect as the original force. The process of calculating the "components" of a force is termed the resolution of the force.

——, **Triangle of** (*Mech.*) If three forces acting at a point be in equilibrium, they may be represented in magnitude and direction by the sides of a triangle, taken in order. *See also* GRAPHIC STATICS.

Force, Tubes of (*Elect.*) *See* TUBES OF FORCE.

Fore Carriage (*Eng.*) The frame carrying the front wheels of a traction engine or locomotive.

—— (*Cycles, etc.*) A light two-wheeled carriage fixed in front of a motor bicycle. The front wheel of the latter is removed, and the forks are connected to levers which act upon the axle of the fore carriage, which is of the Ackerman (*q.v.*) or some similar form. The cycle is thus converted into a light three wheeled car.

Forecasts (*Meteorol.*) A prediction of the probable state of the weather a short time ahead; based chiefly on changes of barometer pressure, etc., which are actually known to be spreading or progressing in a definite direction.

Foredge (*Binding*). The front edge of a book, the edge opposite to the back.

Foreground (*Paint.*) The part of a picture on which objects intended to be nearest the eye of the spectator are presented.

Fore Observation (*Surveying*). The opposite of back observation (*q.v.*)

Foreplate (*Met.*) A guide and resting plate in front of the bottom roll of the finishing grooves or rolls of a forge train (*q.v.*)

Foreshortening (*Paint., etc.*) A method of representing objects or figures, or portions of objects or figures, which lie in a direction not parallel to the plane of a picture, bas-relief, or a piece of sculpture, in order to present the object as it appears to the eye.

Forest Beds (*Geol.*) Strictly speaking, the word "forest" means simply a place outside the limits of cultivation, and has nothing to do with trees. But the term has come to be employed in the sense of extensive wooded areas. Certain strata are found to contain the stumps of trees, apparently in the position of growth. These have been somewhat fancifully described as forest beds. The Forest Bed of East Anglia is part of an ancient delta of the Rhine, and contains many remains of tree fragments along with other organic remains. It is of late Pleiocene Age.

Forest Marble (*Geol.*) A member of the Middle Oolites, which is abundantly fossiliferous in the southern parts of the kingdom. It comprises beds of clay and sandstone, together with a bed of oolitic limestone, which has occasionally been polished and used as marble.

Forge (*Eng.*) (1) A blacksmith's hearth, with its accessories. (2) A blacksmith's shop.

—— (*Met.*) In iron works the department in which the puddled ball is converted into puddled bars by shingling, blooming, and rolling. Cf. MILL.

Forged Scrap Iron (*Eng.*) Small pieces of waste wrought iron from the smith's shop which have been welded up into bars. If properly welded up, this scrap is of considerable value, and often preferable to new rolled bars, on account of its strength. *See also* FAGOT.

Forged Work (*Eng.*) Wrought iron work prepared by the blacksmiths.

Forge Pigs (*Met.*) Pig iron suitable for conversion into wrought iron by PUDDLING (*q.v.*)

Forge Scale (*Eng.*) The scales or flakes of black oxide of iron produced in working wrought iron.

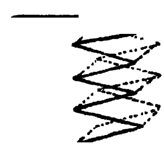
Forge Tests (*Eng.*) Tests applied to wrought iron and steel by bending. The greater the angle through which a plate or bar bends without fracture, the better the iron; this angle is often stated in specifications. The test may be applied both to hot and to cold iron.

Forge Train (*Met.*) A train of two pairs of rolls (ranging from roughing rolls to finishing grooves) in which the shingled bloom from the squeezers or steam hammer is rolled into slabs or bars without reheating. Also called PUDDLING ROLLS. They revolve at 50-80 revolutions per minute.

Forging Machines (*Eng.*) Machines by which definite shapes can be given to wrought iron by forcing it into discs, etc., either by a powerful press or by mechanically driven hammers or stamps.

Fork (*Cycles*). The portion of the machine in which the wheel revolves. In motor cycles the front forks are built up of several rods instead of two only, to make them sufficiently strong to stand the heavy stresses.

Forked Heading Joint (*Joinery*). A joint used in fastening two boards end to end. The ends of the boards to be joined have V-shaped pieces cut out to intersect with each other.



FORKED HEADING JOINT.

Forked Lightning (*Meteorol.*) The ordinary form of lightning, resembling an electric spark on a very large scale. The term "forked" is really a misnomer, as the spark is sinuous or wavy, with branches like a river and its tributaries.

Form (*Art*). A term used to denote the qualities of *line* as distinguished from colour.

—— (*Min.*) *See* SYSTEMS OF CRYSTALS.

—— *or* **Forme** (*Typog.*) Pages of type or stereotype plates arranged in the order for printing a sheet (*q.v.*), and secured by an iron frame or chase (*q.v.*)

Formaldehyde (*Chem.*) $\begin{matrix}H\\|\\HCO\end{matrix}$ (Formic aldehyde). A gas with penetrating smell. When liquefied it boils at $-21°C$. Ordinarily it is met with in aqueous

solution. It is prepared by passing the vapour of methyl alcohol mixed with air through a heated tube containing copper gauze. It is a powerful disinfectant, and a 40 per cent. solution is sold under the name of FORMALIN for disinfecting purposes; a trace of it added to milk will keep the milk fresh for several days. It has the usual reactions of an aldehyde, except with ammonia, with which it yields hexamethyleneamine (or hexamethylenetetramine), $(CH_2)_6N_4$, a crystalline solid readily soluble in water: used in medicine under the name UROTROPINE as a urinary antiseptic. Formaldehyde readily reduces silver and gold solutions to the metallic state. When its aqueous solution is evaporated, it polymerises to paraformaldehyde, $(CH_2O)_n$, an amorphous solid which yields formaldehyde vapour on heating. Used in this way as a disinfectant under the name PARAFORM. When a weak solution of formaldehyde is allowed to stand with slaked lime, it undergoes condensation to a substance FORMOSE, from which a fermentable sugar called methose has been obtained, which is identical with α-acrose (inactive lævulose). Formaldehyde is believed to play an important part in the formation of starch by plants. Under the influence of the chlorophyll the atmospheric carbon dioxide is changed to formaldehyde, which is then polymerised to a sugar, from which the starch arises.

Formalin (*Chem.*) *See* FORMALDEHYDE.

Format (*Printing*). The dimensions of a book (shape, size), *e.g.* octavo, quarto, etc.

Formates (*Chem.*) Salts of FORMIC ACID (*q.v.*)

Formation (*Geol.*) A name applied, in a somewhat vague sense, to an assemblage of rocks which have some character in common, generally that of age; but the term is used also in referring to the origin of the rocks or to their petrographical character. Thus rocks are said to belong to the stratified formation as distinguished from eruptive; to ancient, as distinguished from modern formation to calcareous, as distinguished from argillaceous, arenaceous, or other formations. Of late years terms of more precise meaning have begun to come into use to express each of these several ideas.

Formation of Clouds (*Meteorol.*) *See* CLOUDS.

Former (*Eng., etc.*) (1) A general name for a tool used to produce some one definite shape in a piece of metal. (2) A TEMPLATE (*q.v.*) or gauge used to test some shape when produced.

Formeret (*Architect.*) A wall rib. *See* RIB AND PANEL VAULT *and* WALL RIB.

Formic Acid (*Chem.*) $\begin{matrix} H \\ | \\ COOH. \end{matrix}$ A pungent smelling liquid; boils at 101° C.; soluble in water; blisters the skin (cause of sting of ants and nettles). It occurs in nettles and in ants, and was formerly prepared by distilling the bodies of red ants. It is prepared by distilling oxalic acid with glycerine at 110° to 115° C.; the weak acid (46 per cent.) so obtained is boiled with lead oxide, and the lead formate which crystallises out is dried and treated with sulphuretted hydrogen at 100°, any sulphuretted hydrogen dissolved in the anhydrous acid so obtained being removed by standing over lead formate. The acid reduces ammoniacal silver to the metal $HCOOH + Ag_2O = 2Ag + CO_2 + H_2O$. Heated with sulphuric acid it gives pure carbon monoxide and water. Its salts (the formates) are all soluble in water. Sodium or potassium formate heated with caustic soda gives *pure* hydrogen, $HCOONa + HONa = H_2 + Na_2CO_3$. Ammonium formate, when heated, first gives formamide, $HCONH_2$, then hydrocyanic acid, HCN, by loss of first one and then a second molecule of water.

Formic Aldehyde. *See* FORMALDEHYDE.

Formose (*Chem.*) *See* FORMALDEHYDE.

Forms of Clouds (*Meteorol.*) *See* CLOUDS.

Formula, Chemical. *See* CHEMICAL FORMULÆ.

Forte (*Music*). Loud. *See* "*f.*"

Fortin's Barometer. *See* BAROMETER.

Fortissimo (*Music*). Very loud. Represented by the letters *ff.*

Forum. In ancient Rome the place of assembly for the people, and where judicial and public business was transacted. It occupied a space between the Capitol and the Palatinate Hill. In the time of the Empire the term was extended to the public place or market place of all towns under Roman sway.

Forward Eccentric (*Eng.*) The eccentric (*q.v.*) which drives the slide valve of an engine while it is running in the forward (or usual) direction.

Forwarding (*Binding*). This expression covers all the operations performed in bookbinding up to the time a volume is covered with leather, vellum, etc., when the book is sent to the finishing shop for the gilding. *See* FINISHING.

Fossicker (*Mining*). A person employed in picking up stray pieces of ore from the rock after the main part of the vein has been worked.

Fossicking (*Mining*). Picking out stray fragments of ore after the lode has been worked.

Fossil (*Geol.*) Literally and originally anything that was dug up, but now restricted to organic remains which have been entombed in any of the rocks composing the earth's crust. The science that deals with fossils is palæontology, which is really a branch of biology. With the great extension of knowledge relating to fossils which has taken place within the last fifty years, palæontology has advanced so much that many different branches have arisen, each of which occupies the attention of specialists.

Foucault's Currents (*Elect.*) Currents produced in a mass of iron (or other conductor) when moved across a magnetic field. In electric machinery these currents cause loss of energy, and are kept down as much as possible, usually by dividing up the iron into laminæ parallel to the lines of force which cause the currents. The lines of force have a continuous path, but the Foucault currents have not, and are thereby checked.

Foucault's Measurement of the Velocity of Light. *See* VELOCITY OF LIGHT.

Foulard (*Silk Manufac.*) A thin soft silk cloth, used for ties, mufflers, handkerchiefs, etc.

Fouling (*Eng.*) (1) The deposition of SCALE (*q.v.*) and mud in a steam boiler. (2) The deposition of carbon, etc., in the cylinders, valves, and ports of internal combustion engines. (3) The products of combustion which are deposited in gun barrels, etc.

Foundation Cylinder (*Eng.*) A heavy cast iron cylinder sunk in the ground and often filled with

concrete. It serves to support the foundations of heavy structures or machines when the surrounding ground is not very firm.

Founding. (1) The process of forming an article by pouring molten metal into a mould. *See* CUPOLA *and* FOUNDRY.

—— (*Glass Manufac.*) The period when the furnace is raised to a high temperature in order to fuse the raw materials quickly into glass.

Foundry (*Eng.*) The workshop where castings are made. An IRON FOUNDRY is usually on the ground floor; it is provided with cupola furnaces, cranes, moulding boxes, etc., and has a floor covered with a thick layer of sand. In this floor pits are formed in which large castings are made.

Foundry Ladle (*Eng.*) A heavy iron vessel used for carrying molten iron from the furnace to the moulds in which castings are made. Before being used it is lined or coated with fireclay, which must be thoroughly dry before the molten iron is "tapped" or run into it.

Foundry Pig Iron (*Eng.*) Iron suitable for making castings, but not for conversion into wrought iron.

Foundry Pit (*Eng.*) A large hole or pit in the ground, in which very heavy or very deep castings are made. The mould may be contained in FLASKS (*q.v.*) or may be actually formed in sand, which fills the pit itself.

Foundry Sand (*Eng.*) Sand composed chiefly of silica, and free from earthy matter: used to form the moulds for castings.

Foundry Stove (*Eng.*) A stove used for drying cores and small moulds before they are used for making a casting.

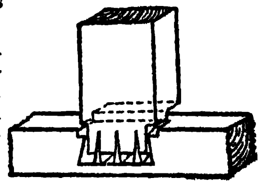
Four Cutter (*Carp., etc.*) *See* PLANING MACHINE.

Fourdrinier (*Paper Manufac.*) The paper machine, so called from the name of the inventor.

Fourier's Theorem (*Phys., etc.*) A periodic curve of any given shape can be formed by compounding together a number of sine curves whose frequencies are simple multiples of one initial sine curve, and whose amplitudes are suitably chosen. The initial or fundamental curve has the same period as the given curve; the successive sine curves will then have frequencies once, twice, three times, etc., the fundamental one. It follows that any wave of complex shape (*e.g.* a sound wave which is not that of a simple tone) can be produced by the combination of a number of waves, the fundamental one having the same period as the given complex wave, the remaining ones having frequencies which are simple multiples. In sound, these remaining tones are the partials or harmonics or the first or fundamental tone; the resulting complex tone has the same pitch (frequency) as the fundamental tone, but of a different quality or "timbre." This difference in timbre is due to the presence of the partials. (*See also* TIMBRE.) The general theorem is expressed mathematically by means of FOURIER'S SERIES. If y be a quantity which varies periodically, going through a complete cycle of changes in time T, then its value at any time t is given by the equation $y = a_0 + a_1 \sin pt + a_2 \sin 2\,pt + a_3 \sin 3\,pt +$ etc., $+ b_1 \cos pt + b_2 \cos 2\,pt + b_3 \cos 3\,pt +$ etc., where a_0, a_1, b_1, b_2, etc., are constant coefficients and $p = \frac{2\pi}{T}$. The equation may also be written y $A_0 + A_1 \sin (pt + e_1) + A_2 \sin (2\,pt + e_2) + A_3 \sin (3\,pt + e_3)$, etc., where $A_1{}^2 = a^2 + b^2$ and $\tan e_1 = \frac{b_1}{a_1}$, the other coefficients A_2, A_3, etc., being similarly obtained.

Four Part Vault (*Architect.*) *See* QUADRIPARTITE VAULT *and* VAULT.

Fox Wedging. A method of wedging tenons without showing the wedges on the edge of the work.



FOX WEDGING.

Foxy (*Chem. Eng.*) A brownish shade which develops in soap made from palm oil or tallow bleached by the muriatic = bichromate, or the chlorine processes. It is attributed to the temperature being too high in the former process, and to excess of chlorine attacking the fatty glycerides in the latter.

Fogging (*Dec.*) A defect of enamelled work in which the surface becomes clouded like blooming in varnish (*q.v.*), caused by the enamel being applied during damp weather.

Fraction (*Chem., etc.*) A portion of a distillate which passes over, or distils, at or about one given temperature. *See* FRACTIONAL DISTILLATION.

Fractional Crystallisation (*Chem.*) A method of resolving a mixture of substances of different solubilities into its constituents by a systematic process of recrystallisation. Suppose the mixture consists of two substances; then on dissolving it in a suitable solvent and leaving to crystallise, the crystals first deposited will be richer in the less soluble substance: these crystals are again dissolved in a fresh portion of the solvent, and left to crystallise—the crystals will be still richer in the less soluble constituent. Crystals may now be obtained from the first mother liquor and recrystallised from the second mother liquor, and so on, until a separation is effected. This process of fractional crystallisation applied to the rare earths has resulted in the discovery of new elements. Marignac discovered gadolinium and samarium in samarskite by fractional crystallisation of the double potassium sulphate salts. Auer von Welsbach discovered neodymium and praseodymium in didymia by fractional crystallisation of the double ammonium nitrate salts.

Fractional Distillation (*Chem., etc.*) A method of separating a mixture of substances into its components by distillation (*q.v.*) Coal tar consists of a very large number of substances. When distilled, the following fractions are collected: (1) Up to 110°; (2) 110° to 210°; (3) 210° to 240°; (4) 240° to 270°; (5) 270° to 400°. From each of these fractions various substances are obtained by a second "fractionation"; *e.g.* from the first fraction after removal of basic and acid substances, benzene, boiling at 81°, and toluene, boiling at 110°, are obtained fairly pure. But in some cases a mixture of only two substances cannot be separated into its constituents by fractional distillation. Alcohol and water cannot be completely separated. If the liquid contain a small amount of alcohol, all the latter and some water can be separated by distillation, leaving water behind; but on repeating the process on the distillate, a stronger alcohol than 95 per cent. cannot

be obtained. Other liquid pairs form mixtures with constant boiling points: thus a mixture of 75 per cent. of formic acid and 25 per cent. of water distils unchanged and has a higher boiling point than any other mixture of these two liquids. *See also* GAS MANUFACTURE: COAL TAR DISTILLATION.

Fractional Pitch (*Eng.*) A screw is said to have a fractional pitch when the number of threads per inch is not a simple multiple or sub-multiple of the number of threads per inch on the leading screw of the lathe on which it is cut.

Fraction of Saturation (*Meteorol.*) The ratio of the pressure of the water vapour actually present in the air to the saturation pressure. Also termed RELATIVE HUMIDITY.

Fracture (*Min.*) A term used to designate the way in which a mineral breaks when the fracture is not due to cleavage (*q.v.*) Fracture may be (1) CONCHOIDAL, as in many glassy minerals, *e.g.* quartz; (2) EVEN, when the plane of division is fairly flat, *e.g.* chert; (3) UNEVEN, *e.g.* copper pyrites; (4) HACKLY, when it is somewhat granular and uneven, *e.g.* cast iron; and (5) EARTHY, *e.g.* chalk.

——, **Surface of** (*Eng.*, *etc.*) The form and nature of the fractured surface in a piece of material broken in the testing machine (or otherwise) gives certain indications of the quality of the material and often of the nature of the stress to which it has been subjected. In the case of metals such as iron it is useful to note whether the surface is crystalline, granular, or fibrous, as the quality of the iron can be inferred to a very large extent from the information thus obtained.

Fragaria (*Botany*). A genus of the order *Rosaceæ*. A well known species is the strawberry, whose fruit consists of a fleshy flower axis (thalamus) bearing numerous seedlike achenes.

Fraise (*Cost.*) A collarette or ruff, much worn during the sixteenth century: a Medici collar.

Fraises (*Her.*) Strawberry leaves as borne by frazer.

Frame (*Chem. Eng.*) A deep rectangular box into which a "made" soap is run from the copper or kettle, in order to cool into conveniently shaped blocks prior to cutting up. At one time the Excise authorities insisted on the frames being of definite proportions; *viz.* 45 in. long by 15 in. wide, and from 45 to 60 in. deep, but the size is no longer compulsory. They are usually made of iron or steel plates, the sides being detachable. There are many special patented types. The Continuous Drying System is superseding their use for toilet soaps and certain classes of "households."

Framed (*Carp.*) Woodwork put together with mortice and tenon joints.

Framed and Braced Door (*Carp.*) A framed door with diagonal braces. The spaces are usually filled in with battens in lieu of panels.

Framed Floor (*Carp. and Join.*) This consists of girders, binders, ceiling joists, bridging joists, and flooring boards. *See also* FLOORS.

Framed Grounds (*Carp.*) Grounds which are put together with mortice and tenon joints. *See* GROUNDS.

Framed Partition (*Joinery*). A partition constructed of panelled framing.

Frame House (*Build.*) (1) A half-timbered house (*q.v.*) (2) A modern building, usually of a more or less temporary character, constructed of wooden framing covered with board, shingling (*q.v.*), corrugated iron, etc. Commonly used in colonies and newly settled districts.

Frame Saw (*Carp.*) A straight saw, or set of parallel saws, fixed in a reciprocating frame, and used for cutting deals or logs into boards.

Frame Wall (*Build.*) A wall formed of a framework of timber, the spaces being filled in with brickwork or masonry. *See also* HALF TIMBERED WORK.

Frame Weirs (*Civil Eng.*) Weirs in which the water is held up by doors carried by heavy frames. These doors can be removed when required. *See* NEEDLE PANEL *and* ROLLING UP CURTAIN WEIRS.

François Vase. *See* VASES.

Frankfort Black (*Dec.*) *See* DROP BLACK.

Frankincense. This resin (also called GUM OLIBANUM) is an exudation from the stem of a tree, *Boswellia carteri* (order, *Burseraceæ*), grown in Somaliland.

Franking (*Carp. and Join.*) A method of joining the cut bars in sashes.

Franklinite (*Min.*) A complex oxide containing iron in the ferrous and ferric state ($FeO \cdot MnO \cdot ZnO$) ($Fe_2O \cdot Mn_2O_3$). Equivalent composition, ferric oxide = 64—66; manganic oxide = 11—18, zinc oxide = 11—25 per cent. Cubic, in black octahedra, and massive. It has a reddish brown streak, and is hard and tough. Chiefly from New Jersey.

Fraunhofer's Lines (*Astron.*) The dark lines crossing the spectrum of the sun in different places. *See* SPECTRUM *and* SPECTRUM ANALYSIS.

Freeman's White (*Dec.*) A non-poisonous white pigment consisting principally of sulphate of lead made from metallic lead by precipitation. It contains also zinc oxide and barytes. It is not affected by sulphurous gases like white lead is, and it possesses good body and covering power.

Free Sand (*Foundry*). Sand which forms a porous mould or core, allowing the escape of gas from the mould.

Free Spring (*Watches*). A balance spring without an "index" or "regulator." Used only in the highest grade watches, as the spring has to be regulated by an expert who moves the timing screws inwards or outwards. More accurate timekeeping is thus obtainable, as any movement of an index might disturb the isochronism. *See* BALANCE SPRING; INDEX; ISOCHRONISM.

Freestones (*Build.*) Stone which does not readily split into layers, *i.e.* which does not possess well marked planes of cleavage. Most suitable for carving. The term is applied in many districts to sandstones (*q.v.*)

Free Vibrations (*Phys.*) The natural vibrations of a body or system when left to itself, as distinguished from forced vibrations (*q.v.*) A body vibrating freely has in general a definite and fixed period of vibration, depending on the mass of the body and the amount of the restoring force exerted on it when a small displacement from its position of equilibrium is produced.

Freewheel (*Cycles*). *See* CYCLES.

Freezing (*Heat*). The process of solidification or changing from a liquid to a solid condition. *See* FREEZING POINT.

Freezing Mixtures. Usually a mixture of some soluble salt with snow, powdered ice, or merely cold water. The rapid solution of the salt lowers the temperature of the mixture. Thus sodium chloride mixed with snow will give a temperature of $-22°$ C., calcium chloride and snow about $-55°$ C., ammonium nitrate and snow $-17°$ C. The best mixture is solid carbonic acid dissolved in ether, which can be made to give $-77°$ C.

Freezing Point (*Phys.*) The temperature at which a liquid substance changes or commences to change into its solid form. In a great number of cases the freezing point is not definite, as in the case of glass, which softens and gradually changes into a viscous solid when heated, and reverses this process when again cooled. The freezing point of a liquid is affected by several conditions, the most important being the variation of pressure. Increase of pressure lowers the freezing point of all those substances which expand on solidification (*e.g.* water), and raises the freezing point of substances which contract on solidification (*e.g.* wax and sulphur). FREEZING POINT OF SOLUTIONS: In general, the freezing point of a solution is lower than that of the solvent. The amount of depression of the freezing point is proportional to the number of dissolved molecules. If the molecules of the dissolved substance are not dissociated (or broken up into simpler molecules) when dissolved, there will be a simple relation between its molecular weight and the depression of the freezing point. If M = molecular weight of the dissolved substance, *m* the weight dissolved in 100 grams of the solvent, *t* the observed depression of the freezing point, then

$$t = K\frac{m}{M},$$

where K is a constant depending on the nature of the solvent employed. The value of K can be found by experiment, or calculated by purely theoretical considerations based upon thermodynamics. If L is the latent heat of fusion of the solvent, T the temperature at which it freezes if pure, then

$$K = \frac{\cdot 02T^2}{L}.$$

The value of K is about 19 for water, 40 for acetic acid, 50 for benzene, 70 for nitrobenzene. The freezing point of dilute solutions is usually determined by means of Beckmann's apparatus. A weighed quantity of the solvent is placed in a tube resembling a test tube, but provided with a side tube through which the substance which is to be dissolved can be introduced. A delicate thermometer divided into hundredths of a degree, and also a platinum stirrer, are introduced into the tube through a cork at the top. This tube is surrounded through the lower half of its length by an air jacket, which is in turn surrounded by a large vessel in which a suitable freezing mixture is placed to effect the requisite lowering of the temperature of the solvent. The freezing point of the pure solvent is first observed, then the tube is removed, the given substance introduced and dissolved in the solvent, and the tube is replaced. The freezing point of the solution can be observed.

French Arch (*Build.*) An inferior form of arch, built of ordinary bricks, which are not cut or rubbed to form true voissoirs, but left in their original form with parallel sides. It is sometimes used to form a horizontal top to an opening, the bricks starting from a sloping jamb and meeting at an angle in the centre.

French Casement (*Build.*) A pair of glass doors in a solid frame.

French Chalk (*Min.*) A variety of steatite or talc (*q.v.*) It is used in marking out cloth, and when powdered it is dusted on to various articles to prevent anything sticking to them, or to act as a lubricant. *See also* SOAPSTONE.

French Curves. A thin plate of wood (usually pear tree), with its edges cut into a series of curves of various radii. Used in drawing curves, not easily obtained geometrically, after certain points on the curves have been found.

French Polishing (*Dec.*) A method of polishing hard wood by applying a special polishing varnish made of gums dissolved in spirit. The recipes for French polishes differ a great deal. One of the best is 1½ lb. of orange shellac dissolved in 1 gal. of methylated spirit, to which has been added 2 oz. of gum sandarach and 2 oz. of gum benzoin. The woodwork to be polished is first "filled" by rubbing in a mixture of plaster of paris and Russian tallow. This having been effected, the polish is applied with a rubber formed of white linen or cotton in such a way as to present a convex surface. The rubber is moistened with linseed oil and polish, and the wood is rubbed with a circular motion, very lightly at first, but with increasing pressure as the work proceeds. The final operation is "spiriting off," which consists in rubbing on prepared spirit, which is prepared like the French polish, excepting that there is a much larger proportion of methylated spirit.

French School of Painting. *See* PAINTING, SCHOOLS OF.

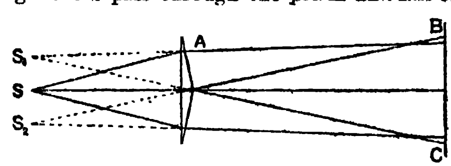
Frequency (*Phys., etc.*) The number of times which a vibration (or other recurring phenomenon) occurs per unit of time; *e.g.* the number of vibrations per second of a tuning fork is termed the FREQUENCY of the fork, or, more correctly, its FREQUENCY OF VIBRATION.

Fresco Painting. *See* PAINTING, METHODS OF.

Freshwater Deposits (*Geol.*) Strata laid down in rivers or in lakes, as distinguished from those deposited upon the land, or in estuaries, or beneath the water of the sea.

Fresnée (*Her.*) Standing on its hind legs.

Fresnel's Bi-Prism (*Light*). A double prism of small angle, as shown at A. If a narrow beam from a single slit S pass through the prism and fall on a



FRESNEL'S PRISM.

screen BC, it will behave as if it came from two sources S_1 and S_2, and interference fringes will be seen on the screen BC. *See also* INTERFERENCE.

Fresnel's Mirrors (*Light*). An arrangement of two mirrors placed with their edges touching and their surfaces inclined at an angle of nearly 180°. Light from a single source falls on the mirrors, and

is reflected so as to fall on a screen. Two beams, inclined at a very small angle, are thus obtained, and interference bands are produced on the screen in a manner similar to those formed by means of Fresnel's Bi-Prism (*q.v.*)

Fresnel's Rhomb (*Light*). A rhomb of glass so constructed that a ray entering along the normal to one end is reflected from the side (by total internal reflection) at an angle of 55°. It then strikes the other side, and is again totally reflected at the same angle, and emerges along the normal to the other end. If the incident light be polarised at an angle of 45° to the plane of incidence, the emergent light will be circularly polarised. If the incident light be circularly polarised, the emergent beam will be plane polarised. The rhomb therefore serves for testing circularly polarised light.

Fret (*Architect.*) A classical ornament used on a flat surface, and consisting of a series of fillets intersecting, usually at right angles, so as to form various patterns.

Frets (*Music*). The small transverse pieces of wood on fingerboards of guitars, zithers, etc., immediately above which the finger must be placed on the string to produce a given note.

Fret Saw (*Carp., etc.*) A very fine saw fixed in a frame, and worked by hand or driven by a machine. It is used in cutting out complicated patterns in thin wood.

Frette (*Her.*) A subordinary: consisting of a saltire and a mascle.

Friction (*Phys.*) The force between two bodies in contact, which tends to prevent their relative motion.

——, Coefficient of. If a body resting on a surface exert on the surface a normal pressure P, it is found that the force F exerted by friction is a certain fraction of the pressure. This fraction is called the COEFFICIENT OF FRICTION, and is usually denoted by the Greek letter μ. We then have $F = \mu P$.

Friction Coupling (*Eng.*) A coupling (*q.v.*) in which the two parts are caused to rotate together by the friction between the two halves of the coupling. These two halves are of various forms; a hollow and a solid cone fitting into each other are often used.

Friction Gearing (*Eng.*) Wheels which are caused to rotate together by the friction of one on the other, instead of by means of teeth. This arrangement is only used, as a rule, to transmit a very small amount of power.

Friction, Kinetic. The amount of the frictional force between two bodies while in motion is termed the KINETIC FRICTION. It is usually less than the static friction. *See* FRICTION, STATIC. Some examples of the coefficients of Kinetic friction are:

Iron on oak, surfaces dry	·62
„ „ „ surface soaped . . .	·21
Iron on iron, very slightly lubricated .	·15
„ „ „ surfaces well lubricated .	·04—·05

Friction Rollers (*Eng., etc.*) Small wheels used to support the axle of a larger wheel. The small wheels rotate, and thereby abolish sliding friction between the axle and its bearing. Ball bearings (*q.v.*) depend upon the same principle, and are superior to rollers.

Friction, Static. The amount of the frictional force between two bodies when just on the point of moving relatively to each other is called the STATIC FRICTION, and the ratio of the frictional force to the pressure of one body on the other is called the COEFFICIENT OF STATIC FRICTION.

Friedel and Craft's Reaction (*Chem.*) Originally only a method of preparing alkyl benzenes by the action of aluminium chloride upon benzene, and an alkyl bromide or iodide, *e.g.*

$$\underset{\text{Benzene.}}{C_6H_6} + C_2H_5Br = \underset{\text{Ethyl Benzene.}}{C_6H_5C_2H_5} + HBr.$$

The reaction has been greatly extended; *e.g.* acid radicals can be introduced in place of alkyl radicals by using an acid chloride in place of an alkyl chloride or bromide, and benzene derivatives can be used in place of benzene itself. The reaction is also a reversible one. Thus, if aluminium chloride be added to toluene and hydrochloric acid gas passed into the mixture, benzene is obtained, and the liberated methyl chloride acts upon unchanged toluene, forming metaxylene and paraxylene.

Frielsebenite (*Min.*) A sulphantimonite of lead and silver, $5(PbAg_2)S \cdot 2Sb_2S_3$. Monosymmetric. The silver amounts to 22 or 23 per cent., so when at all plentiful it is a valuable ore of silver. From Saxony, Spain, and Bohemia.

Frieze (*Architect.*) The central division of an entablature between the architrave and the cornice. It is sometimes spoken of as the ZOOPHORUS. The term "frieze" is also used to denote any band of sculptured ornament and that division of the wall surface of a room immediately below the cornice. *See* ARCHITECTURE, ORDERS OF; ENTABLATURE; ZOOPHORUS.

—— (*Woollen Manufac.*) A thick woollen nap overcoating. Usually made in Ireland.

Frieze Panels (*Joinery*). An upper row of panels, especially the highest panels in a six panelled door.

Frieze Rail (*Joinery*). The rail between the top of a door and the middle rail: used in a six panelled door.

Frilling (*Photo.*) An expansion of the gelatine film by which it forms in wrinkles on the plate. This frequently accompanies the use of too soft a gelatine. It may also be caused by too strong a fixing bath.

Fringe. A border or edging, generally consisting of a narrow band to which are attached threads of some material, either twisted or hanging loose. A fringe may be formed also by leaving the threads of the warp in a fabric after weaving.

Frisbie's Feeder (*Glass Manufac.*) *See* FURNACES, GLASS.

Frisket (*Printing*). An iron frame on which a sheet of paper is pasted. It is used in conjunction with the tympan of a hand press. Its purpose is to lift the printed sheet from the forme and preserve the margins clean.

Frizing (*Leather Manufac.*) Removal of a very thin layer from the grain surface of the skin is called frizing. Buff leather and much glove leather is "frized." *Cf.* BUFFING.

Frog (*Build.*) The recess on one side of a brick.

—— (*Cotton Manufac.*) A cast iron buffer for the stop rod of a shuttle protector of the fast reed type.

Front Hearth (*Build.*) The portion of a hearth in front of the chimney breast.

Frontispiece. The principal illustration in a book or magazine. It faces the title page of a book or other bound volume, but in a magazine the first page of letterpress.

Front Putty (*Build.*) The putty put outside the glass after it is inserted in the sash.

Frost (*Meteorol.*) When the thermometer sinks below the freezing point of water (0° C. = 32° F.) a frost occurs. Sometimes in the British Isles prolonged frosts take place extending over many weeks.

——, Geological Action of. Water finds its way from the surface into the divisional planes and other interstices of rocks of all kinds. When a frost comes, the water in the parts near the surface freezes, and expands in doing so, 174 volumes of water becoming 184 volumes of ice. This expansion takes place with a force which is equal to a pressure of 1,100 lb. to the square inch for each degree below the freezing point. As the temperature falls below freezing the ice contracts, and water may flow in to take its place, freezing in its turn. With a thaw the ice again expands. Hence powerful mechanical forces are exerted, and the surface layers of the rock are shattered.

Fructed (*Her.*) With seeds or fruit.

Fructose (*Chem.*) LÆVULOSE (*q.v.*)

Frue Vanner (*Mining*). A machine by which crushed ore is shaken up under moving water on a wide belt; a separation of the lighter from the heavier parts of the ore gradually results.

Fruit (*Botany*). That part of the flower which remains after fertilisation. The ripened ovary containing the seeds is the essential part of the fruit.

Fruit Sugar (*Chem.*) LÆVULOSE (*q.v.*)

Fuchsine (*Chem.*) Also called Magenta; it is a mixture of the hydrochloride or acetate of rosaniline and pararosaniline, obtained by oxidising a mixture of aniline, orthotoluidine, and paratoluidine. It is a lustrous green solid, dissolving in water with a splendid red colour. Used in dyeing silk, wool, cotton, and leather. *See* PARAROSANILINE *and* ROSANILINE.

Fucus Vesiculosus (*Botany*). The Bladder Wrack. It is one of our commonest brown seaweeds. Together with other species of *Fucus*, it is used as a manure and also as a drug for reducing corpulence.

Fuel. The material which is burnt to produce heat in furnace, etc. *See* COAL, COKE, OIL FUEL, *etc.*

Fughetta (*Music*). A small fugue, *i.e.* not developed at any length.

Fugue (*Music*). A contrapuntal composition consisting of the following parts:—(1) Subject: the theme on which the fugue is founded, generally given out by one part in the score. (2) Answer: the response to the subject; generally a transposition of the subject from the key of the tonic to that of the dominant. If the answer is an exact transposition, it is called a "Real Fugue"; if modified to save modulation, then it is called a "Tonal Fugue." The answer is accompanied by the first voice, or part, and this accompaniment is known as the "counter subject," and is generally in double counterpoint. (3) Exposition: that section of a fugue ending with the last entry of subject or answer (according to the number of parts) by the part that last enters. (4) Episode: free passages developed from material already heard, and serving the double purpose of variety and modulation. These episodes lead back to fresh entries of the subject or answer in new keys. (5) Stretto: the drawing closer together of subject and answer which is often found towards the end of fugues. Besides these parts there is often found a codetta—a few notes inserted between the subject and answer to lead more naturally from one to the other. The greatest master in this branch of composition was Bach.

Fulcrum. The point about which a lever turns.

Full (*Eng.*) A loose expression indicating that the dimensions of some object slightly exceed their nominal value: the opposite of BARE (*q.v.*)

Full Bound *or* **Whole Bound** (*Bind.*) Applied to a book the covers of which are completely covered in leather or some expensive material. The highest style of work.

Fullering (*Eng.*) (1) Producing grooves in forged work. (2) Caulking a boiler by hammering down the edge of the plates.

Fullering Tool (*Eng.*) A tool whose end is suitably shaped for producing grooves of some required section. *See* FULLERING.

Fuller's Earth (*Geol.*) Literally a kind of clay which readily absorbs grease, and especially the oily matter found in connection with sheep's wool. In a geological sense the Fuller's Earth is a member of the Jurassic rocks, and is essentially a series of beds of clay and marl with nodular masses of earthy limestone. It includes some bands of clay suitable for the purpose indicated by its name. In composition it is a hydrous aluminium silicate of the approximate composition, silica = 45, alumina = 20, water = 25 per cent., with other substances to 10 per cent. Found in various dull shades of grey, green, and brown. Soft and earthy; soapy to the touch; very porous. From Reigate and Bletchingly in Surrey; near Bath, Kent, etc.

Full Gear (*Eng.*) An engine is in full gear when the link motion (*q.v.*) is set so as to produce the greatest amount of motion or travel of the slide valve.

Fulling (*Woollen Manufac.*) *See* FELTING.

Full Moon (*Astron.*) The moon when in opposition (*q.v.*) and appearing fully illuminated.

Full Shroud (*Eng.*) A SHROUD (*q.v.*) on a toothed wheel extending right up to the tips of the teeth.

Full Thread (*Eng.*) A screw with its thread cut to its proper section; one which is properly completed, as distinguished from a partly cut thread.

Fulminates (*Chem.*) Salts of FULMINIC ACID (*q.v.*)

Fulminating Gold (*Chem.*) $AuN.NH_3.3H_2O$. A green or brown solid obtained by the action of ammonia on auric oxide. When dry it explodes on percussion or on heating.

Fulminating Silver (*Chem.*) NAg_3. A black solid obtained by allowing a solution of silver oxide in ammonia to evaporate. It is very explosive when dry; if touched with a feather it explodes; less explosive when wet.

Fulminic Acid (*Chem.*) $C:NOH$. The free acid is not known in a pure condition, owing to its in-

stability; it decomposes when liberated from its salts by acids, forming hydroxylamine and formic acid. It smells like prussic acid, and is poisonous. MERCURIC FULMINATE, $(C:NO)_2Hg$ (fulminating mercury), is obtained by dissolving mercury in nitric acid and adding alcohol. It forms white needles, insoluble in water. On heating or on percussion it explodes violently, forming carbon monoxide, nitrogen, traces of other gases (CO_2 and H_2), and mercury: it is very largely used in the preparation of percussion caps and detonators for other explosives. Strong hydrochloric acid yields fulminic acid, which decomposes as above. With benzene and aluminium chloride it yields benzaldoxime, $C_6H_5C:NOH$ (proof of constitution). SILVER FULMINATE resembles mercury fulminate, and is prepared in a similar way. It is more explosive than the mercury salt, friction with a glass rod being quite sufficient to explode it.

Fumant (*Her.*) = smoking.

Fumaric Acid (*Chem.*)
$$\begin{array}{c} H.C.COOH \\ \| \\ HOOC.C.H \end{array}$$
. A white crystalline solid sparingly soluble in water. It occurs in Iceland moss and in certain fungi. It is obtained from mallic acid (*q.v.*), with which it is stereoisomeric (*see* STEREOISOMERISM) by heating in a sealed tube to 200°, or by acting upon it with hydrochloric acid. On heating, it gives maleic anhydride and water. Potassium permanganate oxidises it to racemic acid (*q.v.*)

Fumarole (*Geol.*) A volcanic vent from which only gaseous products escape.

Fundamental Bass (*Music*). That note from which a chord is built up; also called the root.

Fungi (*Botany*). A lowly class of plants of parasitic or saprophytic habit, and devoid of chlorophyll. They range from the simple thread-like moulds to the complex mushrooms and toadstools.

Funicle (*Botany*). The stalk which attaches the ovule to the placenta.

Funnel (*Eng.*) The chimney of a marine boiler: sometimes applied to that of a locomotive or portable engine.

Fur. The long silky hair of many mammals. The furs of commerce are derived from the hare, rabbit, beaver, sable, bear, marten, stoat, etc.

—— *or* **Fir** (*Build.*) To support a ceiling, etc., by FURRING (*q.v.*)

Furcræa (*Botany*). A genus of the *Amaryllidaceæ*, *F. gigantea*. From tropical America; yields a valuable fibre called MAURITIUS HEMP.

Furfuraldehyde (*Chem.*)
$$\begin{array}{l} CH = CH \\ | \qquad\quad >O \\ CH = C.CHO \end{array}$$
. A colourless liquid smelling like benzaldehyde: turns brown on exposure to air: somewhat soluble in water: readily soluble in alcohol and in ether: can be detected even in small quantity by the red colouration it gives with aniline in presence of hydrochloric acid. It is obtained by distilling bran with dilute sulphuric acid; also by distilling pentoses (*e.g.* Arabinose) with hydrochloric acid. In its chemical behaviour it bears an extraordinary resemblance to benzaldehyde; *e.g.* with dimethylaniline and zinc chloride it gives a green colouring matter analogous to malachite green (*q.v.*) By the action of dry hydrobromic acid gas on ketohexoses (*e.g.* lævulose) and on cellulose, a purple colouration is obtained: this is due to a furfuraldehyde derivative—α-brommethylfurfuraldehyde,
$$\begin{array}{l} CH = C.CH_2Br \\ | \qquad\quad >O \\ CH = C.CHO \end{array}$$
.

Furfurane (*Chem.*),
$$\begin{array}{l} CH = CH \\ \beta_1 \quad \alpha \\ \quad\;\; \alpha_1 >O \\ CH \;\; CH \end{array}$$
. A colourless liquid with characteristic smell; boils at 39°: insoluble in water. A pine shaving moistened with hydrochloric acid is coloured green by the vapour of furfurane. It occurs in pinewood tar. It is prepared by distilling barium pyromucate. *See* MUCIC ACID *and* ACETONYL ACETONE.

Furfurol (*Chem.*) FURFURALDEHYDE (*q.v.*)

Furlong. *See* WEIGHTS AND MEASURES.

Furnace, Electric. The electric furnace consists of an arrangement by which materials can be submitted to the heat of an electric arc. In one form (fig. 1) A is a metal case with a refractory lining B, inside which is placed a crucible C. Two carbon rods D and E are supported by holders G and H, insulated from the case. Materials can be introduced by removing the cover F. The current is supplied by leads K and L. The furnace requires a potential difference of 50 to 70 volts, and may use a current varying from 25 to 400 ampères. By the aid of a furnace of this form Moissan has fused lime, and has obtained calcium, chromium, etc., in the metallic form. The HÉROULT FURNACE is shown in fig. 2.

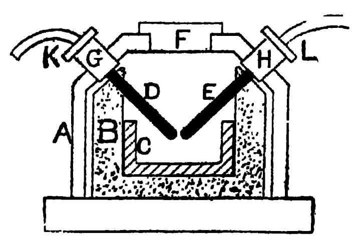


FIG. 1.—ELECTRIC FURNACE.

A is a casing of metal, B a lining built up of carbon plates cemented by carbonaceous matter, *e.g.* tar. This lining forms the crucible, and also serves as the cathode (*q.v.*) The anode consists of a number of plates of carbon E held in position by suitable clamps and insulated from the metal case A. Material can be introduced through openings at G and H, and fluid metal can be withdrawn through a tapping hole D. The current enters by conductors K and L. Aluminium is now produced by means of furnaces of this pattern.

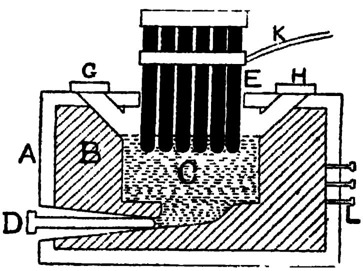

FIG. 2.—ELECTRIC FURNACE (HÉROULT).

Furnace Lining (*Metallurgy*). Infusible material, such as fireclay, which protects the main walls of a furnace from the action of the heat or the corrosive effect of the molten metal and slag. In certain cases (*e.g.* the Bessemer converter) the lining itself contains materials which contribute to the process by assisting in the formation of slag, etc.

Furnaces, Glass (*Glass Manufac.*) Glass furnaces may be classified either according to the method by which they are heated or the use for which they are intended. The principal forms are as follows:—DIRECT FIRING FURNACE: A furnace, circular or rectangular in plan, in which the fuel (coal or coke) is admitted either through an aperture at the side or ends, or from beneath. The latter method of supplying fuel may be effected by means of FRISBIE'S FEEDER, which is a mechanical contrivance for winding up fuel from beneath the grate bars, through a circular aperture, into the furnace. It consists of a bucket or hopper with a movable bottom, which is forced upwards by a lever connected to the machinery. GAS FURNACE: This is circular or rectangular. The most economical is Siemen's regenerative furnace. Coal undergoes destructive distillation in a gas producer, and the gases formed, after passing through a REGENERATOR, enter the furnace, where, on coming in contact with air, they burst into flame, producing intense heat. The hot gases, conveying waste heat from the furnace, are allowed to pass through other regenerative chambers (two pairs being employed), and these in their turn serve to heat up the gas as it passes from the producer, and also the air from outside, before it enters the furnace chamber. A TANK FURNACE is used for melting bottle and window glass. It consists of one long rectangular basin or tank, one end of which is semicircular, and at this end the working or gathering holes are situated. The raw materials are inserted at the opposite end. The furnace is heated by gas (Siemen's principle). Floating vessels (*q.v.*) are placed in the molten glass at the circular end, and from these the metal is gathered. LEAD GLASS FURNACE: This is circular in shape, and contains from eight to twelve pots, those in general use being about 36 in. wide by 40 in. high, hooded or covered over. Space is allowed between each pot as it stands upon the siege and within the furnace, to allow the hot gases to surround them previous to passing into flues, which are placed at each intervening space. The furnace can be worked either by direct firing or on the gas regenerative principle. SHEET GLASS FURNACE: This may be either a POT or TANK FURNACE, and can be worked as a direct firing or as a gas furnace. It is rectangular in plan, with an arched crown or roof. The pots, which are open at the top, are placed in parallel rows at the longest side of the furnace, which contains from eight to sixteen pots. A PLATE GLASS FURNACE is similar in construction, but before each pot hinged doors (lined with slabs of fireclay) are placed, to allow the pot to be removed from the furnace for casting purposes. A GLORY HOLE is a small furnace used for reheating the glass during manipulation or manufacture.

Furnaces, Metallurgical. Metallurgical furnaces may be classified as follows: (1) Furnaces in which the fuel and ore are in contact. These may be again divided into OPEN HEARTHS, constructed on very similar principles to the ordinary smith's forge, and which are suitable for simple operations such as ROASTING and LIQUATION (*q.v.*); and CLOSED HEARTHS, in which the furnace possesses a tall body of more or less cylindrical form. Of the latter, the chief forms are the BLAST FURNACE and the CUPOLA FURNACE. In the blast furnace (fig. 1) the body of the furnace is of brick or stone, often cased with wrought iron plates, or heavily hooped, and having an inner lining of firebrick, separated from the outer portion by a layer of sand or cinders. This forms a porous mass through which gases expelled from the brickwork can escape. The body is not truly cylindrical, but usually widens out in the centre, resembling in section a part of two cones placed base to base. The widest part B is termed the BELLY, the conical portion below the Belly is termed the BOSHES, while the part above B is termed the STACK. The part from L to K is termed the THROAT, and is surmounted by a TUNNEL HEAD (not shown in the sketch). The lowest part A is termed the HEARTH; here the molten metal collects, with the slag floating on top of it. The air or BLAST is forced into the furnace by jets C, termed TUYERES (*q.v.*), which enter the furnace some way above the hearth. Usually the jets are each surrounded by a water jacket, and are then termed WATER TUYERES. The object of the jacket is to cool the nozzle of the jet, and so prevent, as far as possible, its rapid destruction by the intense heat of the furnace, which may be over 1,500° C. In the SCOTCH TUYERE the nozzle is formed of wrought iron tube, coiled to form a truncated cone, enclosed in an iron casing, the cooling water circulating through the whole coil. There is an opening into the bottom of the furnace, leading out into a space F, called the FORE HEARTH; the latter is closed by a wall of firebrick D, termed the DAM, which is supported by a large casting E, the DAM PLATE. There is an opening in the top of the dam, termed the CINDER NOTCH, through which slag is withdrawn, and another in the bottom, termed the TAP HOLE, through which the molten iron can flow when required. This hole is, of course, closed during smelting until a sufficient amount of fluid iron has collected in the hearth. The charge of iron ore, coal, and flux is introduced into the furnace from a platform G running round the top, termed a CHARGING GALLERY, and it is caused to spread out by a large CONE H, which fits a cup or rim K round the mouth of the furnace. When the cone is lowered by a chain, a space is left through which the material can fall; when the cone is brought back into place, the mouth of the furnace is thereby closed, and the waste gases escape by means of large tubes LL. The heat carried away by these gases is utilised for heating the blast, and the gases themselves, consisting largely of carbon monoxide (CO), can be treated for the recovery of by-products and burnt as gaseous fuel. The CUPOLA FURNACE is very similar in principle to a blast furnace; its chief use is the melting of cast iron for the foundry. (2) Furnaces where the ore or metal is not in contact with the fuel. These may again be subdivided, according as the metal, etc.,

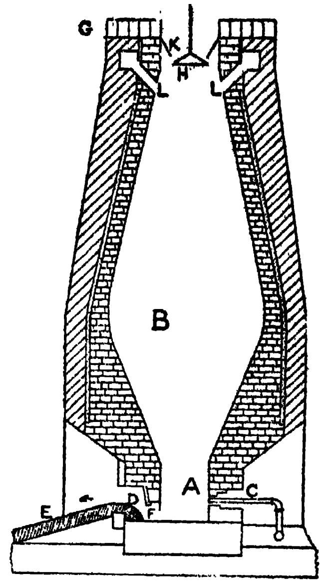

FIG. 1.—BLAST FURNACE.

is placed on a part of the hearth, but separated from the fuel, or placed in a special receptacle, such as a crucible, muffle, retort, etc. The first kind is usually a REVERBERATORY FURNACE (fig. 2). The hearth is divided into two areas, A and B, separated by a low wall of firebrick D, termed the FIRE BRIDGE. In the part A is the fire, in the other the metal or ore. The roof C of the furnace is so shaped as to deflect the flames from the fire down on to the ore, and thence onward to the flue. A PUDDLING FURNACE is of this type, and is used with natural draught (*q.v.*) in the conversion of cast into wrought iron by the operation of puddling (*q.v.*) Furnaces in which a special receptacle is used take a great variety of forms. In the simplest CRUCIBLE FURNACE or POT FURNACE a crucible is merely sunk into the mass of burning fuel contained in a furnace of any convenient shape. In RETORT FURNACES, used in the Belgian zinc process, the furnace is a vertical chamber, in which are fixed rows of closed retorts (*q.v.*) of fireclay. A MUFFLE FURNACE may be compared to an oven; it consists of a long flat-bottomed chamber of fireclay, surrounded by the fuel or hot gases, in which either crucibles or cupels (small shallow dishes of bone-ash or other material of an absorbent nature) can be placed. GAS FURNACES are used on a small scale in the laboratory; they consist of a fireclay body, into which project burners of the Bunsen type, producing a non-luminous flame of very great heating power. On a large scale gas furnaces are commonly worked by a cheap gas of very low illuminating power, such as DOWSON GAS, PRODUCER GAS, or MOND GAS (*q.v.*) In the REGENERATIVE FURNACES of Siemens and others the waste gases escape through a chamber filled with a mesh of brickwork, which very soon becomes heated. The waste gases are then turned off through another similar chamber or REGENERATOR, and the supply of unburnt gas or of air which supplies the furnace is allowed to enter through the first chamber. In this way a considerable amount of heat is utilised which would otherwise be wasted, and great economy of working is secured.

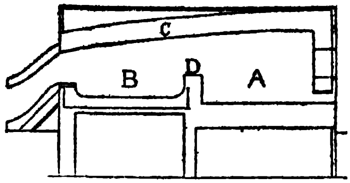

FIG. 2.—REVERBERATORY FURNACE.

Furniture (*Typog.*) The term furniture includes all those pieces of wood or metal that are used in making margin for the folding of books; for fastening the pages of type in the chase; or locking up forms when they are imposed. It is generally classed as reglet, furniture, sidesticks, footsticks, and quoins.

Furring *or* **Firring** (*Carp.*) Thin strips of wood, used to raise some part of a roof, floor, etc., slightly above the level of the timbers which carry the weight.

—— (*Eng., etc.*) The deposition of solid matter in pipes, boilers, etc. The solids are carried in the water (or other fluid) which flows through the pipes, either on suspension or in solution.

Furs (*Her.*) *See* HERALDRY.

Fuse (*Mining*). The device used for igniting a blasting charge. The old slow match and similar devices are now often replaced by an arrangement for producing an electric spark. The latter device renders the time of firing more certain, and is very much safer in case of a miss-fire.

Fusee (*Watches, Clocks*). A pulley of varying radius fixed to the arbor of the main wheel for the purpose of equalising the "moment" of the pull of the mainspring. A continuous groove cut in its surface from end to end carries the chain or cord. *See* GOING BARREL *and* MAINTAINING POWER.

Fusil (*Her.*) A subordinary, of lozenge shape, but of greater length than breadth.

Fusion (*Heat*). The melting of a solid, or the change from the solid to the liquid state.

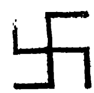
——, **Latent Heat of** (*Heat*). The amount of heat required to melt unit mass of a given solid without raising its temperature. The latent heat of fusion is given out when the body solidifies again, and may give rise to a marked increase in temperature, which is well shown in the common lecture experiment on the solidification of sodium sulphate.

Fustian (*Textile Manufac.*) A name for any class of grey cotton cloth of heavy make, having a weft pile surface which requires cutting, *e.g.* corduroys and velveteens.

Fustic. A yellow wood used in dyeing. It is obtained from the trunks of two trees: (1) *Chlorophora tinctoria* (order, *Moraceæ*); (2) *Rhus cotinus* (order, *Anacardiaceæ*).

Futures Cotton (*Cotton Trade*). A system of dealing by means of which a spinner may cover himself from loss when he has accepted a contract for spun yarn, and does not want to buy all his cotton at once. This legitimate system has been greatly abused by gambling transactions.

Fylfot (*Her.*) A mystic symbol said to be formed of four Γ's arranged in the shape of a cross; consequently called Gammadion. It has been extensively used as a decoration (perhaps a mystic symbol) in almost all parts of the world.



g (*Eng., Phys., etc.*) The letter "g" is used as a symbol for the acceleration produced by gravity; *i.e.* about 32·2 ft. per sec. per sec., or 981 cm. per sec. per sec. in England.

G (*Music*). The sixth note in the scale of C.

Ga. Chemical symbol for GALLIUM (*q.v.*)

Gab (*Eng.*) A notch, catch, hook, etc., in a lever which enables a temporary connection to be made between the lever and a projecting pin for actuating some piece of mechanism. The connection can be made or broken as required.

Gabbro (*Geol.*) A rock of eruptive origin which resembles granite in its structure, but consists of the same minerals as those forming basalt and dolerite. The constituent minerals are usually one of the lime soda felspars and one of the pyroxenes, together with titaniferous magnetite. Olivine is generally present. It is usually a rock of deep seated origin, and has, in most cases, been formed in the deeper part of the core of a volcano.

Gaberdine (*Cost.*) A long loose upper garment, much worn in the fourteenth century, and at a later date by shepherds, almsmen, and Jews.

Gable (*Architect.*) That form of roof termination in which the end wall is carried up vertically above the eaves to meet the ridge. Such an end wall is known as a Gable End.

Gab Lever (*Eng.*) A lever provided with a GAB (*q.v.*)

Gad (*Mining*). A wedge driven into a crack in a rock to split it.

Gadlings (*Armour*). Small spikes fixed to the knuckles of gauntlets. Worn during the fourteenth century.

Gagget (*Glass Manufac.*) A SPRING PONTY (*q.v.*)

Gait, Gaiting (*Textile Manufac.*) (1) The adjustment of a loom for weaving. (2) The space between two carriages when in working position on the machine.

Galactose (*Chem.*), $CH_2OH \, . \, (CHOH)_4CHO$. A white crystalline solid (hexagonal plates); melts at 163°; is soluble in water; has a sweet taste; reduces Fehling's solution about threequarters as strongly as dextrose; it is dextrorotatory. It is obtained by boiling milk sugar with dilute sulphuric acid, removing excess of acid by baryta, concentrating and adding a few crystals of dextrose, when galactose crystallises out, leaving the dextrose in solution. It has the general properties of the aldohexoses. *See* SUGARS. On reduction it yields dulcitol; on oxidation with bromine water it yields the monocarboxylic acid GALACTONIC ACID; on oxidation with nitric acid it yields the dicarboxylic acid MUCIC ACID.

Galaxy, The (*Astron.*) Another name for the Milky Way - the luminous belt of irregular width and outline which surrounds the heavens nearly in a great circle.

Galbanum (*Botany*). *Ferula galbaniflua* and *F. rubricaulis* (order, *Umbelliferæ*). A gum resin used in pharmacy, obtained from these and other species of *Ferula*.

Gale (*Meteorol.*) A wind blowing with great force, *i.e.* with a velocity of forty miles or more per hour. The word has no very exact or scientific meaning.

Galea (*Armour*). The Latin term for a helmet.

—— (*Botany, Zool., etc.*) Applied to various structures which either in shape or function serve as a helmet; *e.g.* the upper lip of a labiate flower; a horny cap on the head of a bird.

Galena (*Min.*) Lead sulphide, PbS. Lead = 86·6, sulphur = 13·4 per cent., with silver up to even 3 per cent. The silver probably exists as the isomorphous sulphide Argentite. Crystalline system cubic. More often it occurs massive in veins with barytes, quartz, calcite, zinc blende, fluorspar, etc. When fresh it is a brilliant metallic grey; almost black when weathered. It splinters on attempting to cut it with a knife. *Cf.* ARGENTITE. When the silver is over 8 to 12 oz. to the ton and worth extracting, it is called ARGENTIFEROUS GALENA, and the mines come under somewhat different conditions. If the trace of silver is left in the lead, it has rather more value for certain purposes. It is the chief ore of lead. From Cumberland, Westmoreland, Northumberland, Cornwall, Leadhills, Isle of Man, etc., and a great many places abroad.

Galilee (*Architect.*) A chapel, or a porch used as a chapel, usually built near the west end of a Gothic church. The galilee porch of Lincoln Cathedral is on the west side of the south transept.

Galileo (*Astron.*) The celebrated Italian astronomer who lived 1564—1642. He was the first to observe the heavenly bodies by means of the telescope.

Gall Bladder (*Zoology*). An outgrowth from the bile duct acting as a reservoir for the bile. It lies under cover of the lobes of the liver.

Galleïne. *See* DYES AND DYEING.

Galley (*Archæol.*) (1) A long low seagoing ship with one deck, at one time in common use in the Mediterranean. It was propelled by sails and oars, the rowers being generally slaves or criminals condemned to the galleys. They were frequently chained to the seats. (2) The term is also applied to Greek and Roman warships with one or more banks of oars. (3) A large open rowboat.

—— (*Typog.*) A flat piece of metal or wood with ledges on end and on one or two sides. It is used to receive type as composed.

Gallic Acid (*Chem.*),
$$\begin{array}{ccc} & C\,.\,COOH & \\ HC & & CH \\ HOC & & COH \\ & COH & \end{array} .$$
Silky needles; melts at 220°; not easily soluble in cold, readily in hot. water. It occurs in tea and some other plants. It is prepared from tannin (*q.v.*) by boiling with dilute sulphuric acid, or from gall nuts by maceration and allowing the cold liquid from the maceration to stand in air, when it ferments, forming gallic acid. When heated, gallic acid yields pyrogallol, $C_6H_3(OH)_3$ (*q.v.*) Ferric chloride gives a blue black precipitate. Its alkaline solution absorbs oxygen from the air and turns brown. On account of its power of reducing gold and silver salts to the metal, it is used in photography. The basic bismuth salt is used as a dry antiseptic under the name DERMATOL. Heated with strong sulphuric acid, it forms RUFIGALLIC ACID, a hexaoxy-anthraquinone.

Gallium (*Chem.*), Ga. *Atomic weight*, 70. A bluish white metal; melts at 30° to a silvery white liquid, which does not readily solidify again. The solid can be cut with a knife. It readily dissolves in hydrochloric acid or caustic soda solution. It is obtained by electrolysis of an alkaline solution of the sulphate. Gallium belongs to the aluminium group of metals, and forms an ammonium alum. The existence of this metal was predicted, and it was discovered by means of the spectroscope in zinc blendes from the Pyrenees, which contained less than sixteen parts per million.

Gallocyanine (*Chem.*),
$$\left.\begin{array}{r} HO \\ HO \\ HOOC \end{array}\right\rangle C_6H \left\langle\begin{array}{c} N \\ O \end{array}\right\rangle C_6H_3 : N \left\langle\begin{array}{l} OH \\ (CH_3)_2 \end{array}\right. .$$
Brilliant green needles, sparingly soluble in water. It is obtained by the action of nitrosodimethylaniline hydrochloride on gallic acid in hot alcoholic solution. It is an important dye, especially in calico printing, giving violet shades. *See* DYES AND DYEING.

Gallon. *See* WEIGHTS AND MEASURES.

Galloon. A close-woven braid composed of wool, cotton, or silk, combined with worsted; generally narrow. Used for trimming various articles of wearing apparel and on furniture. A kind of gold or silver lace, made of threads of gold or silver woven into a pattern; used on uniforms, etc.

—— (*Lace Manufac.*) When applied to lace means a double edged lace with well defined scallops.

Gallotannic Acid (*Chem.*) *See* TANNIN.

Galloway Boiler (*Eng.*) A form of Lancashire boiler provided with Galloway tubes. *See* BOILERS.

Galloway Tubes. *See* BOILERS.

Galls (*Botany*). Excrescences formed on the leaves of the oak by the Gall-wasp (*Cynips*). The insect punctures and deposits its eggs in the tissues of the leaf, and a poison introduced causes an excrescence to form.

Galmei (*Min.*) A synonyn for the silicate of zinc, HEMIMORPHITE (*q.v.*)

Galon (*Lace Manufac.*) *See* GALLOON.

Galton's Stove (*Build.*) The principle in this stove is the utilisation of heat which in the ordinary firegrates would be wasted. At the back of the grate an air chamber is constructed which is provided with two openings, one connected with the outer air and the other with the room. Air from without enters, and, being warmed by contact with the heated back and sides of the grate, rises up through a shaft which opens into the room between the mantelshelf and ceiling. All communication is cut off between the smoke flue and the air shaft. This principle is taken advantage of in constructing and fitting modern grates.

Galton's Whistle (*Phys.*) A sounding pipe, resembling in principle a very small closed organ pipe, producing a note of very high frequency. Used in experiments on the limits of audition.

Galvanised Iron (*Eng., etc.*) Sheet iron coated with zinc in order to prevent oxidation. The process is not electrical, as the name erroneously implies, but consists simply of dipping the iron into melted zinc. Under the influence of moisture and atmospheric impurities, the iron and zinc form an electric couple, and corrosion of the iron results. Pinholes, or small defects in the coating of zinc, facilitate this action.

Galvanometers (*Elect.*) A galvanometer is an instrument for detecting an electric current, or, within certain limits, for measuring its value. Practically all galvanometers depend for their action on the mutual effect of a magnet and an electric circuit, and they may be classified into two main groups. In the first or older form of galvanometer a small magnet is suspended or pivoted, so that it can turn freely inside a hollow coil of insulated wire which carries the current; in the second or more modern type, known as SUSPENDED COIL GALVANOMETERS, a small coil suspended so that it is free to turn between the poles of a powerful fixed magnet. The first group include the following forms: (1) The SIMPLE GALVANOSCOPE with a pivoted needle, controlled by the Earth's field (and therefore pointing N. and S. when at rest), and only suitable for detecting comparatively large currents. (2) ASTATIC GALVANOMETER, with two similar and nearly equal magnets rigidly fixed together parallel to each other, with their poles pointing in opposite directions. One needle is inside the coil of the instrument, the other is either outside or else in a second coil, in which the current flows in the opposite direction to the current in the first coil. As the two magnets are subject to opposite and nearly equal forces due to the Earth's magnetism, the controlling effect of the latter is very small, and the instrument is very sensitive, *i.e.* it turns with a very minute current. A SINE GALVANOMETER is one in which the coil itself can be rotated (by hand) about the same axis as that about which the needle turns; it is provided with a horizontal scale by means of which the angle through which the coil has been turned can be measured. The coil is first placed so that the plane of its windings lies in the magnetic meridian. The current is then passed, and the coil rotated in the same direction as the needle until the latter again lies in the same plane as the needle, and the angle through which it has been turned from its original position in the magnetic meridian is read. The amount of the current is proportional to the sine of this angle, *i.e.* $C = k \sin \theta$. A single observation on a current of known value gives the value of the constant k. A TANGENT GALVANOMETER is one with a coil of large diameter, usually wound on a hoop of wood or brass. In the centre of this hoop is suspended (or pivoted) a short magnetic needle, which is usually provided with a long pointer moving over a fixed scale, by means of which the deflection of the needle may be observed. The coil is set in the plane of the magnetic meridian; the current is then proportional to the *tangent* of the angle of deflection, or $C = K \tan \theta$. The constant K is termed the REDUCTION FACTOR of the instrument. It may be found by means of an observation of the deflection produced by a known current, or it may be calculated from a knowledge of the size and number of turns of wire on the coil, if the local value of the Earth's horizontal magnetic force be known. If the average radius of the various turns of wire constituting the coil be r, and the number of turns be n, and H be the horizontal magnetic force, θ the deflection produced by a current whose amount in absolute units is C, then $C = H \frac{r}{2\pi n} \tan \theta$. The quantity $\frac{2\pi n}{r}$ is often denoted by G, and is known as the GALVANOMETER CONSTANT. Thus the Reduction Factor is equal to the horizontal magnetic force, divided by the galvanometer constant, or $K = \frac{H}{G}$. In all the above galvanometers a small deflection can only be detected by fitting a long pointer, which adds considerably to the mass (or, rather, to the Moment of Inertia) of the suspended magnet, and reduces its sensitiveness. To overcome this difficulty, the REFLECTING or MIRROR GALVANOMETER is used. This possesses a small magnet fixed to a very light mirror. The system is suspended inside the coil of the instrument by a fine fibre of unspun silk or of quartz. *See* QUARTZ FIBRES. The deflection may be observed in two ways: in the system commonly used in England a beam of light is thrown by means of a lamp and a suitable lens on the mirror, and reflected by it so as to fall on a divided scale. The beam of light then serves as a weightless pointer, whose length may be increased at will without affecting the mass of the moving parts. In the second method, which is the one most used in Germany, a reading telescope is focussed on the mirror; a divided scale is fixed in a horizontal position just above or just below the object glass of the telescope, and the image of its divisions can be seen reflected in the mirror. As the latter turns, successive divisions are brought into view, and the amount of the deflection can be read. It should be noted that the beam of light turns through *twice* the angle of deflection of the mirror. A mirror galvanometer is usually fitted with a CONTROLLING MAGNET, which is attached, with its axis

horizontal, to a vertical rod projecting from the top of the instrument. By turning this magnet, the galvanometer needle may be brought to rest in any convenient position, independent of the magnetic meridian. By raising or lowering the magnet, the sensitiveness of the galvanometer may be increased or diminished. The sensitiveness of a galvanometer may be increased by using a very large number of turns of wire on the coil, by diminishing the radius of the coil, and by making the suspended system as light as possible. In this way instruments have been constructed which are capable of detecting a current of 10^{-13} ampères, a current so small that it would require centuries to liberate a cubic centimetre of hydrogen (J. J. THOMSON). The second group, the SUSPENDED COIL GALVANOMETERS, possess a powerful fixed magnet, bent into a horseshoe shape, so that its poles are close together. In the gap between the poles a coil of fine insulated wire is suspended by a very thin flat strip or a fine wire, which serves to conduct the current from one terminal of the instrument to the coil. The circuit is completed either by a second suspending wire alongside the first (thus forming a bifilar suspension) or else by a wire or helical spring running from the lowest point of the coil to a conductor fixed on the base of the instrument. This class of instrument are often termed D'ARSONVAL GALVANOMETERS. They are unaffected by the Earth's magnetism or any other external magnetic field; they can be made practically dead beat (*vide infra*), and can be constructed to work in various positions. The following definitions apply to both classes of galvanometers alike: An APERIODIC or DEAD BEAT galvanometer is one in which the suspended system (needle or coil) is prevented from swinging backwards and forwards after the current has either ceased or become steady. The checking of the motion is termed DAMPING; it may be effected by mechanical or by electrical means. The best method, applicable to the D'Arsonval type, is to wind the coil on a metal frame or enclose it in a metal tube (Ayrton and Mather's method). As this frame or tube oscillates in the magnetic field between the poles of the magnet, currents are induced in the metal which tend to bring it to rest (*see* LENZ'S LAW). A BALLISTIC GALVANOMETER is one in which the damping is very slight; it usually possesses a comparatively heavy needle. It is used for measuring the transient currents produced when a quantity of electricity is discharged through the instrument. The sine of half the angle of the first swing is proportional to the total quantity of electricity which has passed through the coil. The exact expression for this quantity is $Q = \frac{HT}{\pi G} \sin \frac{\theta}{2}$, in which Q is the quantity of electricity, H the strength of the Earth's field (or, more generally, of the controlling force, which may not be due to the Earth's field), T the time of swing of the needle, G the galvanometer constant, and θ the angle through which the needle swings. The degree of sensitiveness, or FIGURE OF MERIT, of any galvanometer is determined by the amount of current required to deflect the needle (or spot of light) through one division of the scale. In a reflecting galvanometer this will depend upon the distance between the mirror and scale.

Gambeson (*Armour*). A tunic of thick cloth or leather, worn in the thirteenth and fourteenth centuries as a defence, or under the habergeon or hauberk to prevent chafing.

Gamboge. A gum resin derived from a tree (*Garcinia*; order, *Guttiferæ*) which grows extensively in Siam and Ceylon. It is usually imported in the form of sticks or cylinders, but sometimes in cakes or lumps. The resin is soluble in ether, alcohol, and water. It gives a bright yellow colour, and is employed as a water colour, but is not permanent, *i.e.* is bleached by the sunlight. It is not much used ground in oil, but is useful as a bright transparent glaze. It is employed somewhat extensively for colouring yellow spirit varnishes and golden lacquers. Analysis shows gamboge to consist of about 3 parts resin and 1 part gum.

Ganglion (*Zoology*). A group of nerve cells occurring in connection with nerves.

Gangue (*Mining*). A term for the matrix which encloses the ore within a metalliferous vein. It may consist wholly or in part of broken pieces of the country rock, or it may be mixed in variable proportions with any of the vein minerals, such as quartz, barytes, fluorspar, calcite, limonite, etc.

Gangway (*Mining*). A general name for a passage.

Gannister (*Geol.*) A compact and usually fine grained sandstone consisting of nearly pure quartz grains cemented by a siliceous matrix. It is, in fact, a variety of quartzite (*q.v.*) which occurs in connection with some few coal seams. It is of considerable commercial value as a constituent of the refractory materials used for lining iron furnaces and other chambers exposed to a very high temperature.

Gantrees (*Cotton Manufac.*) Beams or girders to support Jacquard machines over power looms.

Gantry (*Build.*) A stage built over the pavement to work on; foot passengers pass underneath.

—— (*Eng.*) The frame which carries the mechanism of an overhead crane.

Gap Bed (*Eng.*) A lathe bed having an opening near the headstock to admit an object of larger diameter (*e.g.* a wheel) than the actual distance between the line of centres and the surface of the bed. When not in use the gap can be filled by a casting termed the BRIDGE or GAP BRIDGE, whose upper surface is similar in form to, and continuous with, the lathe bed.

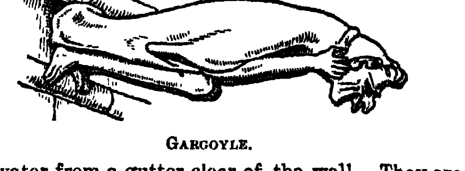
Gap Bridge (*Eng.*) *See* GAP BED.

Gap Lathe (*Eng.*) A lathe with a GAP BED (*q.v.*)

Garage (*Motor Cars*). A depôt for the storage or (storage and repair) of motor cars.

Garden Wall Bond (*Build.*) A method of bonding 9 in. walls, one header to every third or fourth stretcher.

Gargoyle *or* **Gurgoyle** (*Architect.*) A spout projecting from the face of a building and throwing



GARGOYLE.

the water from a gutter clear of the wall. They are sometimes quite plain, but more usually grotesquely carved.

Garnet (*Min.*) This name is applied to a group of minerals, all of which consist of anhydrous silicates, crystallising in forms of the cubic system. The following are the more important:

(1) Calcium Aluminium Garnet . ($Ca_6Si_3O_{12} . Al_4Si_3O_{12}$)
(2) Magnesium Aluminium Garnet ($Mg_6Si_3O_{12} . Al_4Si_3O_{12}$)
) Iron Aluminium Garnet . . ($Fe_6Si_3O_{12} . Al_4Si_3O_{12}$)
) Manganese Aluminium Garnet ($Mn_6Si_3O_{12} . Al_4Si_3O_{12}$)
) Calcium Iron Garnet . . . . ($Ca_6Si_3O_{12} . Fe_4Si_3O_{12}$)
) Calcium Chromium Garnet . ($Ca_6Si_3O_{12} . Cr_4Si_3O_{12}$)

Garnierite (*Min.*) A hydrous nickel magnesium silicate, containing approximately 30 per cent. of nickel oxide. It is an amorphous mineral, apple green to white in colour, occurring in considerable quantity in veins in serpentine in New Caledonia. Also found in the United States.

Garter, Order of. The Order of Chivalry instituted by Edward III., one of the most famous in the world. The emblem is a blue ribbon bearing the motto, "Honi soit qui mal y pense," in gold letters. It is always represented as part of the Royal Arms, and surrounds the shield. Members of the Order also wear other insignia, including a collar with the "George," the star, the mantle, and the ribbon of blue, to which is attached the "Badge" or "Lesser George." Knights of the Garter place after their names the letters K.G., which takes precedence of all other titles.

Garth (*Architect.*) An enclosed space, such as the quadrangle enclosed by the cloisters. *See* CLOISTERS.

Gas (*Phys., etc.*) A gas is a fluid which, when introduced into any given vessel, expands and fills the vessel. It has no finite surface or volume of its own, both being determined by the surface and volume of the vessel in which it is contained.

Gas Barrel. The wrought iron tube used for conducting gas from the large mains (usually of cast iron) into buildings, and up to the point from which it is distributed by "compo" pipes (an alloy of lead).

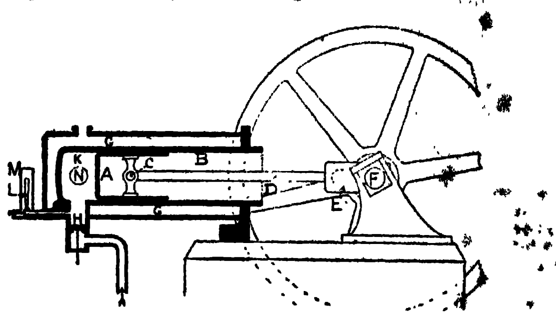
Gas Carbon (*Chem.*) A dense form of nearly pure carbon found lining the retorts in coal gas making, sometimes called artificial graphite. It is used in making the carbon electrodes in arc lamps, and in making the carbon poles of Bunsen and other primary cells.

Gas Coke. The ordinary coke resulting from the distillation of coal in gas works. Distinguished in the arts and trades from coke which has been prepared in ovens for special use in metallurgical or other operations, which is usually much harder and denser than gas coke. *See* COKE.

Gas Cylinders (*Lantern Work*). Compressed gases are sent out in steel cylinders, whose capacity is given by the number of cubic feet of gas measured at atmospheric pressure, which can be pumped into them without the pressure rising to a dangerous amount. A 40 ft. cylinder is about 32 in. long and 5½ in. diameter. The mouth is fitted with a valve opened and closed by a strong screw.

Gas, Dissociation of. The splitting up of a complex molecule of a gas into simpler molecules or into single atoms.

Gas Engines. The term Gas Engine is often used as a synonym for an INTERNAL COMBUSTION ENGINE, *i.e.* one in which the energy is obtained by the combustion or explosion of a gaseous charge, mixed with air, in the cylinder of the engine itself. It is more correct, however, to confine the term to those engines which are supplied with gas manufactured by separate plant, as distinguished from oil and petrol engines (*q.v.*) A somewhat diagrammatic representation of a typical gas engine (Crossley's) is given in the figure. A is a piston (of the TRUNK



GAS ENGINE.

or tubular form) working in a cylinder B, and attached by a pin at C to a connecting rod D. The connecting rod actuates a crank E, and drives the main shaft F, on which is the flywheel of the engine. The cylinder is surrounded by a water jacket GG, through which a current of cold water flows, in order to prevent the cylinder from becoming overheated. The ADMISSION VALVE H is opened by the valve gear at the commencement of a cycle (*vide infra*), just as the piston commences to move from left to right. A mixture of gas and air is drawn into the cylinder during the stroke; at the end of the stroke, H is closed, and the piston, as it returns, compresses the mixture of gas and air in the space K, which is termed the CLEARANCE SPACE, COMPRESSION CHAMBER, or IGNITION CHAMBER. The mixture is then ignited (caused to explode) by the opening of a timing valve, which allows a portion of the gas to flow into an IGNITION TUBE L. This tube is maintained at a red heat by means of a burner in the outer tube M. The explosion of the gas in the cylinder drives the piston forward again, thus performing useful work, a portion of which is stored up in the flywheel, and serves to keep the engine running during the remainder of the cycle. The completion of the series of operations is effected by the opening of an exhaust port N; the return stroke drives out the burnt gases, and when this operation is complete N closes, H opens, and a fresh cycle begins. The valves are generally worked by means of a subsidiary LAY SHAFT driven from the main shaft F by bevel gearing; suitable cams and levers connected to this shaft actuate all three valves; *viz.* H, N, and the TIMING VALVE, which controls the ignition. This complete CYCLE or series of operations occupies two revolutions of the engine or four strokes of the piston; it is termed the OTTO CYCLE. The engine has only one working stroke out of four, or one impulse in two revolutions, and the action of the engine will be very unsteady unless a very heavy flywheel be employed. For this reason modifications of the simple type described above are now made. One class of gas engines is made double acting, so that an explosion occurs on each side of the piston alternately. In another form, often termed TWO-STROKE or (incorrectly) TWO-CYCLE engines, the charge is forced into the cylinder before the end of the exhaust stroke by means of a separate or DISPLACER PUMP. The compression is completed in the cylinder

by the main piston, and the ignition and working stroke follow as in the OTTO CYCLE. The main piston may serve as a displacer, drawing the charge into the front end of the cylinder or into a CRANK CHAMBER, an enclosed space containing the piston, connecting rod, and crank, and provided with air-tight bearings for the crank shaft and with a suitable valve for the admission of the gas and air. In this space the charge is compressed sufficiently to force it into the main cylinder, just before the end of the return or exhaust stroke, as above described. The fresh charge serves to expel the exhaust gases; the exhaust port then closes, and compression occurs. This two-stroke cycle has been applied both to large and small engines, and especially to small petrol engines (*q.v.*) The changes in pressure and volume which occur in the cylinder of a gas engine are well shown by its INDICATOR DIAGRAM (*q.v.*) The methods of igniting the charge, which are to a large extent common to all classes of internal combustion engines, are dealt with under IGNITION (*q.v.*) *See also* OIL ENGINES *and* PETROL ENGINES. The theoretical efficiency of a gas engine (*see* EFFICIENCY OF HEAT ENGINES) is much higher than that of a steam engine; this is due to the very high temperature attained by the gases after the explosion. This efficiency may be as high as ·7 or ·8; the practical efficiency is less than one-third of this. But owing to the high theoretical efficiency, it is more economical (*i.e.* more work is obtained) to turn fuel (coal or oil) into gas, and use it to drive a gas engine, than to use the fuel either in the solid or liquid form to produce steam for a steam engine. On this account the use of gas engines is largely increasing, especially in cases where a cheap form of gas, such as MOND GAS (*q.v.*), can be obtained.

Gaseous Fuel (*Eng.*) Coal gas is employed to heat very small furnaces. On a larger scale, PRODUCER GAS (*q.v.*) is used on account of its much greater cheapness. *See* FURNACES.

Gaseous Steam (*Eng.*) Steam which has been heated to above its saturation temperature, *i.e.* SUPERHEATED STEAM (*q.v.*)

Gases, Density of (*Phys.*) *See* DENSITY OF GASES.

——, **Diffusion of** (*Phys.*) *See* DIFFUSION.

——, **Expansion of** (*Phys.*) *See* EXPANSION.

——, **Kinetic Theory of** (*Phys.*) *See* KINETIC THEORY OF GASES.

——, **Liquefaction of** (*Phys.*) *See* LIQUEFACTION OF GASES.

——, **Velocity of Sound in** (*Phys.*) *See* VELOCITY OF SOUND IN GASES.

Gas Governors. *See* GAS REGULATORS.

Gasket (*Eng.*) Rope or yarn plaited together and used with grease for filling or packing the stuffing boxes (*q.v.*) of engines. Also metal packings of various materials used in fixing boiler fittings to the boiler shell on surfaces which cannot be "faced.' Gaskets of fine brass wire (set in red-lead putty); corrugated copper (most serviceable for large joints which have to be taken apart periodically); hard rubber; or sometimes merely copper wire or small lead pipe laid in a groove on the flange, are among those most commonly employed.

—— (*Plumb.*) In plumbers' work tow (gasket) is packed round the spigot in the socket of an iron pipe before the lead is run in.

Gas Liquor (*Chem.*) When coal is dry distilled, as in coal gas making, there are produced liquid as well as gaseous products. The liquid products separate into two layers: the lower layer is coal tar and the upper layer is a watery liquid containing compounds of ammonia. To the watery liquid is added the water used in washing the coal gas free from ammonia: the whole is what is called gas liquor. It contains a large number of ammonia compounds, chief among which are the carbonate, chloride, sulphide, thiosulphate, and cyanide. Gas liquor is the chief source of ammonia and its compounds. *See also* GAS MANUFACTURE.

Gas Manufacture. The distillation of coal, as carried on in gasworks, gives rise to three main products: A. COAL GAS: B. COAL TAR; C. AMMONIACAL *or* GAS LIQUOR. Each of these is a very complex mixture of various substances, and the two latter serve as the raw material for the preparation of a very large number of organic substances. The actual processes, as carried on in the gasworks, are described here.

A. COAL GAS.—Coal of suitable character is heated to a red heat in tubular chambers of fireclay, known as RETORTS, from which iron pipes serve to convey the gaseous products to the CONDENSING APPARATUS. The end of the pipe from each retort is bent over, forming a DIP PIPE, which dips from 1 to 3 in. into water contained in a large horizontal tube, termed the HYDRAULIC MAIN. The more volatile products condense in this main, and are drawn off into a receptacle called the TAR WELL. The gas now passes through a series of vertical tubes exposed to the cooling action of the air. This apparatus is called an ATMOSPHERIC CONDENSER. The lower ends of the tubes dip into water, in which more of the volatile constituents (chiefly tarry) condense as the gas gradually cools down. Up to this point the gas has been kept at a pressure less than that of the atmosphere by means of exhausting pumps; but after passing the condensers it is forced through the remaining parts of the apparatus under pressure. The next step is to remove ammonia and other soluble gases by subjecting the gas to the action of numerous finely divided streams of water in WASHERS or SCRUBBERS. These were originally tall iron cylinders filled with coke, through which water trickled slowly. Scrubbers are now much more frequently filled with boards, about a foot broad and a quarter of an inch thick, placed on edge, about threequarters of an inch apart, each one being placed at a different angle from the one above it. This pattern of scrubber is far more effective than the old pattern, which became choked with tar, in which condition it lowered the illuminating power of the gas. On leaving the scrubbers, the gas has lost most of its tar and ammonia compounds; but it still contains carbon dioxide and various sulphur compounds, which must be removed. This is done by passing the gas through PURIFIERS, which are shallow perforated trays or sieves filled with moist lime, hydrated ferric oxide, and sometimes Weldon mud (*q.v.*) The process of purification varies considerably in different works, the main point being to reduce the impurities to a certain amount fixed by law, and at the same time to secure the sulphur, etc., in the form of a useful by-product. The lime in the purifiers absorbs the carbon dioxide and sulphuretted hydrogen, forming calcium carbonate and calcium sulphide. As the lime has a greater affinity for the carbon dioxide, the sulphuretted

hydrogen is gradually expelled, passing on to the next box. Calcium sulphide (free from the carbonate) is thus formed, and this arrests the carbon bisulphide, CS_2, in accordance with the equation $CaS + CS_2 = CaCS_3$. The process is still further accelerated by the introduction of a small percentage of oxygen. After leaving the purifiers, the gas passes into GASHOLDERS, in which it is stored under suitable pressure ready for distribution. The composition of coal gas is variable; an average specimen might contain, approximately, hydrogen, 50 per cent.; marsh gas, 33 per cent.; carbon monoxide, 10 per cent.; olefines, 4 per cent.; oxygen, nitrogen, carbon dioxide, sulphuretted hydrogen, etc., 3 per cent. If the ILLUMINATING POWER (*q.v.*) is too low, the gas must be enriched; this is done by the addition of OIL GAS, obtained by heating a heavy hydrocarbon oil, usually a PARAFFIN (*q.v.*), of density ·8 to ·9, or by the addition of ACETYLENE (*q.v.*) By this means the illuminating power is brought up to the standard fixed by law. This is usually fixed at such a value that a burner of specified form, when consuming 5 cubic feet of gas per hour, shall give a light of sixteen candle power.

B. COAL TAR DISTILLATION.—The crude or raw material for this industry is furnished by the gas-works, and is known as gas tar. The constituents of this substance escape from the retorts, and are condensed in the hydraulic mains, condensers, and scrubbers. It collects in large vessels called tar wells, and is either reserved for subsequent treatment by the gas company, or else, as is more usually the case, it is sold to the tar distiller. In its crude condition gas tar always contains a certain quantity of ammoniacal liquor (gas liquor), from which it must be freed before it undergoes distillation. This preliminary dehydration (as it is called) takes place in large wrought iron vessels provided with a dome top. Below the dome roof, but near the top of the vessel, there is fitted a small overflow pipe and cock. When the first charge of tar is run in, the vessel is "fired" from below. As the temperature inside rises, the tar becomes thinner and its bulk becomes greater. The contained water in it gradually rises to the surface and accumulates there. It is then gradually drawn off by means of the overflow pipe mentioned above. When all the contained water has thus been drawn off, the tar, having a greater specific gravity, remains behind in the still. In addition to an overflow pipe, there is fitted near the bottom of the still an exit pipe, also fitted with a cock. This serves to run off the pitch when the whole process of the distillation of the charge has been performed. The gaseous products of distillation (hydrocarbons) are carried away by a pipe leading to a condenser. This consists essentially of a coil or worm immersed in water in a cylindrical vessel. The pipe through which the gases escape leaves the still at the top of the dome, and is, at the commencement, of considerable diameter (about 12 in.), which, however, rapidly diminishes to about 6 in. It makes a sharp turn in its direction at this point, being bent almost at right angles. In addition to this tube, the still is provided with a manhole and safety plug fitted on to the dome roof. The principle which underlies the method of tar distillation is that known as "fractional distillation." It consists in the separate collection of various groups of volatile oils by taking advantage of the fact that between two given temperatures a particular group or family of compounds will pass over from the still, thus permitting a preliminary classification. These compounds undergo condensation as they pass through the condenser, and subsequently flow into a "receiver." The usual classification of these compounds adopted in practice is: I. Crude and light oils, distilled up to 170°; II. Crude carbolic (phenol), distilled up to between 170 and 230°; III. Heavy creosote oils, distilled up to between 230 and 270°; IV. Anthracene oil, distilled up to over 270°; V. Pitch, residue in tar still. I. CRUDE AND LIGHT OILS (average specific gravity about ·98): These contain a variety of substances, and in order to effect their separation, a further process of distillation takes place. During this redistillation, whilst the temperature is between 80 and 110°, two important compounds are driven off. These are known as BENZENE and TOLUENE, and form the basis from which the commercial products known as "90 per cent. BENZOL" and TOLUOL are prepared. The liquid which is collected in the receiver during distillation between 140 and 170° is commonly known as SOLVENT NAPHTHA. II. CARBOLIC OILS: These are heavier than the preceding group, possessing an average specific gravity of 1·003. The two most important compounds derived at this stage are: (*a*) NAPHTHALENE, (*b*) CARBOLIC ACID. (*a*) NAPHTHALENE: This substance crystallises out on cooling in large colourless crystals. It is drained and pressed to squeeze out any adhering carbolic. It is then agitated with concentrated sulphuric acid, and subsequently with caustic soda. The caustic alkali dissolves any carbolic acid that may have been retained by the naphthalene. This latter then undergoes a final distillation or sublimation. When pure, it is often sold as a white solid substance, known variously as "pure candle naphthalene," "albo carbon," or simply as "carbon," which is merely a trade name, as it is a complex hydrocarbon. (*b*) CARBOLIC ACID: This compound, having been dissolved in the caustic soda solution, is recovered by neutralising with H_2SO_4, upon which the carbolic acid separates out as an oily liquid. This oil is then washed with water and is redistilled. It is usually prepared for the market either as "carbolic acid crystals" (pure) or as "liquid carbolic acid" (impure). Its great value lies in its properties as a disinfectant and antiseptic. III. HEAVY CREOSOTE OILS: These are distilled over, and collected at temperatures ranging from 230 to 270°. As these oils become free from the presence of crude carbolic acid, they are characterised by an oily, greasy nature, and possess lubricating properties of a somewhat inferior kind. The colour is usually a yellowish green. Creosote oils may be considered as consisting of two main portions: the first, known as "liquid creosote" (yellow creosote), and the second, a greenish grease or oil. Liquid creosote is used as a liquid fuel and for illuminating purposes. The ordinary creosote is largely used for "pickling" railway sleepers. *See* CREOSOTING. Creosote contains about 40 per cent. crude naphthalene (creosote salts). These salts separate out from the oil, and are deposited in very large quantities at the bottom of the storage tanks in which the liquid is run for storage and cooling. After cooling, the crude creosote salts can be shovelled out and allowed to drain. These salts have a ready sale, as the raw material for refined naphthalenes. IV. ANTHRACENE OIL: These bodies are collected at temperatures of 270° and upwards. They may be regarded as hydrocarbons which are solid at ordinary temperatures. They are separated from the liquid hydrocarbons associated with it by treatment in filter presses or hydraulic presses, after

cooling. This process extracts the green anthracene oil. The crude anthracene contains about 30 per cent. pure anthracene. It is either sold as such or undergoes further purification, such as washing with solvent naphtha, to free it from its impurities. This yields an anthracene of 50 per cent. or even higher. Anthracene may be regarded as one of the most important products of tar distillation, owing to the fact that ALIZARINE—so important in the manufacture of dyes—can be synthesised from it. V. PITCH: This is the final residue remaining in the still after one complete cycle of operations. At the last stage of distillation superheated steam is driven into the still. This serves to sweep out any vapours still remaining, and helps to break up the hard crust on the bottom of the still, thus preventing "coking" of the pitch. The pitch is then run off from the exit pipe whilst still hot and liquid into the "pitch cooler." It remains in this closed chamber for an interval of six to twelve hours, until it ceases to give off vapours. When in no danger of taking fire in the open air, it is allowed to flow off from the cooler into the pitch bed, where it is allowed to solidify into a hard, brittle, black mass, not unlike cannel coal in appearance. From here it is hacked and hewed out as required for despatch by barge, truck, or ship. It commands an enormous sale on the Continent, as a "binder" in the manufacture of the "patent fuel" so largely used for locomotive and railway purposes (briquettes). It is also made into "asphalt" by mixing with creosote oil and sand, gravel, or stone chips. It may be added here that the distillation of one ton of gas coal will yield on an average from ten to eleven gallons of tar, from which about eighty pounds coal tar pitch can be produced.

C. BY-PRODUCTS FROM AMMONIACAL OR GAS LIQUOR.—In addition to the large number of useful commercial substances which are obtained by the distillation of coal tar derived from the manufacture of coal gas (*see* COAL TAR DISTILLATION), there is another large and important body of compounds of which AMMONIACAL LIQUOR is the chief source. Ammoniacal liquor (known also as GAS LIQUOR or MOTHER LIQUOR) is formed in the condensers and the scrubbers (*see above*). Ammoniacal liquor is a highly complex aggregate of compounds, in each of which the ammonia plays the part of base. It contains CARBONATES, SULPHIDES, CYANIDES, THIOCARBONATES, THIOSULPHATES, SULPHOCYANIDES, and FERROCYANIDES OF AMMONIA, along with some free ammonia. The first three compounds enumerated along with the free ammonia are removable by boiling, being volatile at ordinary temperatures. The others or FIXED ammonia compounds are removable on boiling with milk of lime. The most valuable commercial products obtained from gas liquor are: (1) Sulphate of Ammonia; (2) Ferrocyanides. Owing to the valuable properties that sulphate of ammonia possesses as an artificial manure, its manufacture is a source of profit to gas companies and corporations. It is by no means unusual to erect a sulphate plant as one of the adjuncts of a gasworks. Sulphate of ammonia contains of nitrogen about 20 per cent. of its weight, and is therefore richer in that element than its chief rival, nitrate of soda, which contains about 16 per cent. of its weight of nitrogen. SULPHATE OF AMMONIA MANUFACTURE: The sulphuric acid which is necessary for the manufacture of this important "residual" is usually derived from the spent oxides of iron from the PURIFIERS of gasworks, or it may be produced from iron pyrites, which is imported in large quantities from Spain and Scandinavia for that purpose. Both these raw materials contain the necessary sulphur—as much as 50 per cent. by weight. *See* SULPHURIC ACID. In the manufacture of sulphate of ammonia the ammoniacal liquor, after being boiled with lime in "lime boilers," is thus freed from its combined ammonia gas. The sulphuric acid is then saturated with ammonia gas in the "saturators." The ammonia is thus converted into sulphate of ammonia. On crystallising out from this concentrated solution, the salt is freed from water by dehydration in CENTRIFUGAL DRYING MACHINES. It is sold as yellow or grey salt, and contains about 25 per cent. of ammonia. FERROCYANIDES AND CYANIDES FROM GAS LIQUOR: These may, along with sulphate of ammonia, be regarded as the two most valuable products recoverable by gasworks from their crude gas liquor. The existence of the cyanogen (CN) radicle in gas liquor has long been known, but it has only been during the last ten years that gasworks have been considered an important source of these compounds. The enormous success which has attended the McArthur Forrest process (in South Africa and elsewhere) for the recovery of gold from "slimes" or "mill tailings" by treatment with a solution of cyanide of potassium has consequently directed much attention to these products during recent years. The principle of the process carried on by several of the largest gasworks in the United Kingdom and on the Continent is the elimination of the cyanogen contained in the gas by forcing the latter to pass through a special mechanical "washer" before entering the purifier. This washer is an apparatus divided into four or five compartments, the last compartment containing a concentrated solution of an iron salt (preferably copperas = sulphate of iron). After forcing the gas through this apparatus for some hours, the SULPHATE of iron is reduced to SULPHIDE of iron, and the ammonia of the gas combines with the acid to form sulphate of ammonia. The sulphide of iron is then attacked by the ammonia and cyanogen of the gas, and is converted into an insoluble double salt, ammonium ferrocyanide. The gas is thus freed from its cyanogen, which remains behind in the liquor. This liquor is of a colour ranging from black to yellowish green, and of a muddy consistency ("cyanogen liquor"). This sludge, or muddy liquor, is boiled until its ammonia is driven off. The insoluble residue, consisting of the double salt of iron and AmCN, is then compressed in filter presses to a CAKE, which contains about 30 per cent. of Prussian blue. Yellow prussiate of potash is prepared from this by fusing with carbonate of potash. Cyanide of potassium (for gold extraction) is prepared by heating prussiate of potash, carbonate of potash, and metallic sodium together in iron crucibles. It should be added that the enormous demand for cyanide of potassium has, during the last few years, led to the perfecting and patenting of many ingenious processes for its manufacture by other means than from the ferrocyanide of gas liquor. These "synthetical" processes aim at the production of alkaline cyanides (chiefly sodium cyanide) by the direct combination of ammonia (giving nascent nitrogen) with carbon in the presence of an alkali metal. Another ingenious method is based upon the removal of sulphur from sulphocyanides by oxidation of the sulphur to SO_2 with nitric acid. The gasworks, however, possess a very valuable source of cyanogen in their liquors, which is readily and cheaply converted into prussiate of potash, to such

an extent that, at the present moment, the cyanide market is suffering from over production.

Gas, Natural (*Geol.*) A native hydrocarbon in a gaseous state which is liberated, usually by artificial means, such as boreholes, etc., from subterranean reservoirs, which occur in various parts of the world. These are commonly associated with deposits of gypsum, anhydrite, rock salt, or some of the minerals which accompany these.

Gasoline (*Chem.*) A low boiling fraction (70° to 90° C.) of American petroleum; used as a solvent and for increasing the illuminating power of coal gas.

Gasoline Engines. PETROL ENGINES (*q.v.*)

Gas Pliers. Strong pliers with curved and toothed jaws in which gaspipe can be held.

Gas Ports (*Eng.*) Apertures in a gas engine cylinder for the admission of the charge of gas.

Gas Producer (*Eng., etc.*) A form of furnace, charged with coke and inferior carbonaceous fuel, through which is blown air and steam. A mixture of hydrogen, oxygen, carbon monoxide, and certain non-combustible gases is formed, known as PRODUCER GAS (*q.v.*) This gas can be burnt, giving a very economical fuel for furnaces and boilers, or it can be used to drive gas engines after it has been purified by simple processes resembling those employed in gas manufacture (*q.v.*)

Gas Pump (*Eng.*) A small pump used in some forms of gas engine for compressing the charge and forcing it into the cylinder.

Gas Regulator (*Lantern Work*). An automatic valve governed by a spring which controls the supply of gas from a gas cylinder: this valve permits a steady flow of gas at a very constant pressure, and the main valve of the gas cylinder need not be touched after it has once been opened, until the supply is no longer required; any necessary regulation of the amount of gas may be done by means of the small taps attached to the oxyhydrogen jet.

—— (*Plumb.*) Special forms of float valve are used as regulators or governors on the service pipes of large institutions to regulate the pressure. They ensure a steady light at the burners, and save waste by flaring.

Gassing (*Chem. Eng.*) A term applied to the poisoning of workmen by sewer and other gases escaping from chemical plant, notably H_2S, N_2O_4, CO, AsH_3, etc. Special rules are now approved by the Home Office for the prevention and treatment of such cases. The remedies are much the same as for cases of drowning, *e.g.* artificial respiration, the use of compressed oxygen, etc.

—— (*Textile Manufac.*) A process for clearing the spun thread of loose fibres or fluff by passing quickly through a gas flame and singeing; this imparts a smooth surface to lace, yarns, etc. *See also* SINGEING.

Gas Stocks and Dies (*Eng.*) Appliances for cutting gas-threads, *i.e.* the fine screw thread used in connecting pieces of iron gas barrel.

Gas Stoves. *See* STOVES.

Gas Tar. *See under* GAS MANUFACTURE.

Gas Thermometers. *See* THERMOMETERS *and* MEASUREMENT OF TEMPERATURE.

Gas Threads. *See* SCREW THREADS.

Gastric Juice. The stomach secretion of animals: in man it may be said to consist of the ferment pepsin (an enzyme), hydrochloric acid, and the chlorides and phosphates of sodium, potassium, ammonium, calcium, magnesium, and iron—all present in very small quantity: water forms 90·5 per cent. of the gastric juice. It converts proteids into peptones which are diffusible; it also acts as an antiseptic. *Artificial* gastric juice is the glycerine extract of the calf's stomach, containing hydrochloric acid.

Gate (*Met.*) Sometimes spelled GEAT or GIT. Also called a SPRUE. (*a*) The channel or ingate by which metal is poured into a mould when casting. (*b*) The metal left in such a channel attached to the casting. There are five kinds of gate, *viz.* (1) POURING GATE; (2) SKIMMING GATE—a recess below the pouring gate for skimming the metal; (3) SPRUE GATES—smaller passages, often two or three in number, leading from the skimming gate to the mould; (4) FEEDING GATES, through which the flow of metal is assisted by agitating with an iron rod; (5) FLOW GATES, up which the metal rises when the mould is full. Nos. 2 to 5 are generally used only in the case of larger castings.

Gatherer (*Glass Manufac.*) The workman who takes the molten glass from the furnace and prepares it for the making of articles.

Gathering (*Binding*). Collecting into volume from printed sheets as they come from the printer. This work is generally done by girls, and may be performed either with the unfolded sheets or with folded sheets which English bookbinders call SECTIONS.

—— (*Build.*) Drawing over the inside of a flue by corbelling.

Gauge (*Build.*) The distance between the battens for slating and tiling.

—— (*Carp. and Joinery*). A tool used for measuring and marking material. *See* MARKING GAUGE, MORTICE GAUGE, *etc.*

—— (*Eng., etc.*) (1) An object used as a standard of measurement. (2) A tool used for making measurements of length (or, less frequently, of area or volume). *See* WIRE GAUGE, *etc.* (3) An instrument for measuring the volume of a fluid (*e.g.* a WATER GAUGE, *q.v.*) or the pressure of a gas (*e.g.* a PRESSURE GAUGE or VACUUM GAUGE, *q.v.*) (4) The distance apart of the rails in a railway or tramway. *See* GAUGE OF RAILWAYS, BROAD GAUGE, NARROW GAUGE, *etc.*

Gauge Cocks (*Eng.*) Small taps or cocks in a boiler, one below and one above the proper water level.

Gauged Arch (*Build.*) *See* ARCH.

Gauged Stuff (*Build.*) Lime putty with a small quantity of plaster of Paris.

Gauged Work (*Build.*) The best kind of brickwork, the bricks being rubbed to shape, set in cement, and jointed with putty (*q.v.*)

Gauge Glass (*Eng.*) A glass tube connected at its ends to the inside of a boiler, so that the upper end is in communication with the steam space, the lower with the water; the level of the water in the tube is the same as the level in the boiler, thus showing at once if the boiler contains the correct amount of water.

Gauge of Railways (*Civil Eng.*) The distance between the inside edges of the rails; this is 4 ft. 8½ in. in England. For light or for temporary railways a narrower gauge is used; thus the Festiniog railway has a gauge of 2 ft. only. The old Broad Gauge, only recently abolished on the Great Western Railway, was 7 ft., and a gauge of 5 ft. or more is used on many lines abroad; in Ireland the standard gauge is 5 ft. 3 in.

Gauge of Tramways (*Civil Eng.*) The standard gauge of 4 ft. 8½ in. is used on most English tramways.

Gault (*Geol.*) A bed of clay of marine origin which, in the south-east of England, lies beneath the Chalk, and forms the lowest member of the Upper Cretaceous Series. The Upper Greensand, or its equivalent, usually comes next above the Gault. It is richly fossiliferous in most localities where it occurs.

Gaultheria (*Botany*). A genus of evergreen aromatic plants (*Ericaceæ*); yields an essential or volatile oil used in pharmacy. Known in the United States as WINTERGREEN.

Gaults. *See* BRICKS.

Gauntlet. A glove, generally made of leather covered with steel plates, worn as a part of mediæval armour. *See* ARMOUR. More recently, a stout glove used in various games and sports. The term is also applied to the part of a glove which widens out and covers the wrist.

Gauss' Theorem (*Elect.*) The TOTAL NORMAL ELECTRIC INDUCTION over a closed surface is 4π times the charge enclosed by the surface.

Gauze (*Textile Manufac.*) A system of weaving in which one set of threads are twisted round the other set, thus producing an open texture fabric. Used for light cloths only. Also styled "cross weaving."

Gay Lussac Degrees. *See* DESCROIZILLES DEGREES.

Gay Lussac's Law (*Chem.*) May be stated thus: when gases combine together they do so in volumes which bear a simple ratio to each other and to that of the gaseous product (all measurements being made at the same temperature and pressure).

Gay Lussac's Measurement of Vapour Pressure (*Phys., Chem.*) *See* VAPOUR PRESSURE.

Gay Lussac Tower (*Chem. Eng.*) A tower suitably packed and attached to the exit of a VITRIOL CHAMBER (*q.v.*) to catch the nitrous gases which escape. Sulphuric acid of 150° Tw. (*see* HYDROMETER) flows down the tower, and dissolves the nitrous compounds as they pass up. *Cf.* GLOVER TOWER.

Ge. Chemical symbol for GERMANIUM.

Gear (*Cycles*). The mechanism by which power is transmitted from the crank axle to the axle of the back wheel. In place of the ordinary chain gear (*see* CYCLES) a bevel gear is sometimes used. Two pairs of bevel wheels are required, connected by a horizontal shaft parallel to or inside one of the horizontal tubes of the back fork. The device is neater than a chain and more easily protected from dust, but more difficult to repair.

Gear (*Eng., etc.*) A term applied in a very wide sense to various arrangements of mechanism, sets of tools, or appliances, etc. In particular, a set of toothed wheels working together.

Gear Cases (*Cycles*). Light cases of leather or celluloid suffice to keep much dust from the chain: these are properly termed GEAR COVERS. A true GEAR CASE is a metal case which not only excludes dust, but is capable of containing a bath of oil at its lowest point; this oil efficiently lubricates the chain and chain wheels.

Gear Cutters (*Eng.*) Milling wheels or circular toothed cutters, used for forming or finishing off the teeth of wheels.

Geared Flywheel (*Eng.*) A flywheel with teeth on its outer edge, for driving some mechanism direct from the engine.

Geared Lathe (*Eng.*) *See* BACK GEAR.

Gear, Height of (*Cycles*). Multiply the diameter of the back wheel by the number of teeth on the large chain wheel, and divide by the number of teeth on the small wheel. The result is the size of the back wheel which would have to be used to carry the rider the same distance in one revolution of the pedals, if the latter were directly fixed to the axle, as in the old high bicycle.

Gearing (*Eng.*) Sets of gear wheels, *i.e.* toothed wheels working together.

Gearing Down (*Eng.*) Reduction of the speed of rotation by means of a set of gear wheels, as in the headstock of a back geared lathe or in the mechanism used to communicate the motion of the motor of a car to the axle of its driving wheels.

Gearing Up (*Eng.*) Increasing [illegible] speed [illegible] rotation of one shaft relatively t[illegible]r by connecting them by a train or set [illegible]eels or some equivalent device.

Geat (*Foundry*). A GATE (*q.v.*)

Gedact Work (*Music*). Those organ stops belonging to the flue work, which consist of closed pipes.

Gedge's Metal. *See* AICH METAL.

Gegenshein (*Astron.*) A bright patch, 10° or 20° in diameter, seen in the sky on the opposite side of the horizon to the rising or setting sun.

Gelatine. A brittle, amorphous, transparent solid; insoluble in cold water, but it absorbs from 5 to 10 per cent. of it, and swells during the process. It is also insoluble in salt solutions, acids, and alkalis. It readily dissolves in hot water, and the solution on cooling forms a jelly. The gelatinising temperature is 30° C. Its chemical constitution is entirely unknown. It contains about 50 per cent. carbon, 6·5 to 7 per cent. nitrogen, 17 to 18 per cent of hydrogen, ·2 to ·7 per cent. of sulphur, and about 25 per cent. of oxygen. Its decomposition products (by putrefaction, treatment with alkalis or acids) resemble those of albumins in many respects, but differ in the large amount of glycocoll (*q.v.*) which is always obtained from gelatine, and in the absence of tyrosine (*q.v.*) Gelatine is obtained from connective tissue, from skins, from the swimming bladder of fishes, and from bones by the prolonged action of boiling water or superheated steam. The gelatine from the swimming bladders is known as ISINGLASS; that from bones, which is not so pure, is called GLUE. Its preparation from bones is as follows: The bones are soaked in weak acid till soft, then washed; digested with superheated steam; the product is run into vessels and allowed to settle; the fat skimmed from the top,

and the gelatine bleached, if required, by sulphurous acid, and filtered; then concentrated by steam pipes. Gelatine is used in preparing jellies, sweets, photographic plates, in numerous copying processes, in clearing soups, etc. Gelatine belongs to the class of substances known as albuminoids; though richer in nitrogen, it cannot replace proteids in a diet.

Gems. *See* PRECIOUS STONES.

Genera (*Biol.*) *See* GENUS.

General Fog (*Photo.*) A partial reduction of the silver salt all over the film during development. There are a number of causes which tend to bring about this, such as exposing the plate to an unsafe darkroom lamp, keeping plates in an unsuitable manner, etc.

General Joiner (*Carp., etc.*) A machine used for a variety of wood working operations—sawing, planing, drilling, etc.

Generating Circle (*Eng.*) The small circle which traces out the cycloidal curve required in setting out the teeth of wheels. A point in the generating circle which rolls on the PITCH CIRCLE (*q.v.*), traces out the curve required.

Generating Surface (*Eng.*) The heating surface of a boiler.

Genouillère (*Armour*). A jointed and flexible piece of armour forming the covering for the knee. *See* ARMOUR.

Genre Painting (*Paint.*) Applied to a style of painting (or to a picture) which depicts scenes of everyday life. The finest examples of genre painting are the pictures by the early Dutch artists. Amongst British artists Hogarth and Wilkie have left notable examples.

Gertian (*Botany*). The bitter tonic medicine is prepared from the dried root of *Gentiana lutea* (order, *Gentianaceæ*), imported from Southern France.

Gentianaceæ (*Botany*). A natural order of *Dicotyledons*, comprising plants of varied habitat. Some of the plants are medicinal.

Genus (*Biol.*) A genus is a group of SPECIES which possess certain structural characteristics in common. A plant or animal is usually denoted by two names: the first or GENERIC NAME being the name of its genus; the second or SPECIFIC NAME being added to denote the species, and thereby to distinguish it from the other species which are included in the same genus. Thus the zoological genus *Felis* includes the Lion (*Felis Leo*), Tiger (*Felis Tigris*), Wild Cat (*Felis Catus*), etc. The botanical genus *Ranunculus* includes the Buttercup, *Ranunculus Acris*; the Great Spearwort, *Ranunculus Lingua*, etc. *See also* SPECIES, ORDER, *etc.*

Geocentric (*Astron.*) A term used when referring measurements to the centre of the earth.

Geodesy. The branch of Applied Mathematics dealing with the measurement of the form and dimensions of large portions of the Earth's surface, or of the Earth as a whole.

Geognosy. A term which was in general use up to the middle of the nineteenth century for the department of Geology which is concerned with rocks (*per se*), and without reference to either their age or their origin. It included two important subdivisions, which were: PETROLOGY (properly so termed), or the study of rock masses as they occur in the field; and LITHOLOGY, or the department of science which is concerned with the mineral constitution of rocks, or the study of specimens by means of the microscope.

Geological Time. A chronological measure (of a somewhat indefinite character) which bears the same kind of relation to the measures of time used in history that the distances of the stellar bodies do to the ordinary standard of terrestrial measurement. Wide differences of opinion exist in regard to the Age of the Earth, as expressed, for example, in centuries. Those who base their conclusions mainly upon certain physical considerations usually set the figure at a much lower estimate than geologists as a whole find themselves able to accept.

Geology. The science dealing with the events that have occurred upon or within the Earth prior to the Dawn of Civilisation. It deals with everything relating to the Succession of Life upon the Earth, to the changes in its physical geography, to the structure and history of its rock masses, to the antecedents of its present surface relief, and to the origin and mode of occurrence of the Earth's economic products. In more general terms it may be said that Geology deals with the History of Former Changes of Life and Land.

Geometrical (*Architect.*) One of the periods into which Sharpe divided Gothic architecture. The name given to the type of tracery used in the geometrical period—the earliest form of bar tracery. This kind of tracery is principally formed of regular figures, such as circles, trefoils, etc., and is much more formal than the later tracery of the Decorated period.

Geometrical Slide. A device which causes a moving part of some apparatus to have certain DEGREES OF FREEDOM (*q.v.*) and no others, so that it shall always move in the same path.

Geometrical Stairs (*Carp., etc.*) Stairs that have a continuous handrail and outside string.

Geometric Clamp (*Phys., etc.*) A device for fixing some part of a piece of apparatus so that it has no DEGREE OF FREEDOM (*q.v.*); that is, its retention in position depends upon the fulfilment of certain kinematical conditions, and not upon any mere application of force: it can be removed and replaced in the identical position it originally occupied.

Geometry. (1) The branch of mathematics which deals with lines, areas, and solids, as distinguished from algebra, which deals with abstract quantities. (2) The branch of the art of drawing which deals with the construction of mathematical figures.

Geraniaceæ (*Botany*). A natural order of *Dicotyledons*, of world-wide distribution. Many of the plants have aromatic and astringent properties.

German Degrees (*Chem.*) *See* DESCROIZILLES DEGREES.

Germanium (*Chem.*) Ge. Atomic weight, 71·8. A very rare metal belonging to the carbon group in the periodic system (*q.v.*); its existence was predicted by Mendélejeff. It was discovered in a very rare silver mineral, ARGYRODITE; also occurs in the rare mineral EUXENITE. It is a lustrous, greyish white, brittle metal obtained by heating the oxide GeO_2 with carbon. Heated in chlorine it forms the tetrachloride $GeCl_4$, a colourless fuming liquid.

German School of Painting. *See* PAINTING, SCHOOLS OF.

German Silver (*Met.*) An alloy of copper (50 to 60 per cent.), nickel (15 to 25 per cent.), and zinc (15 to 20 per cent.) A German silver containing 1 to 2 per cent. of tungsten is called PLATINOID. These alloys have a high electrical resistance—platinoid higher than German silver—which increases uniformly between 0° and 100° C.

Gersdorffite (*Min.*) Nickel sulpharsenide,
$NiS_2 . NiAs_2$;
cubic, in bright tin white crystals, often with a greyish black tarnish. From Sweden, Styria, the Harz, Thuringia, and in good crystals from near Ems.

Geyser (*Geol.*) An intermittent thermal fountain occurring in connection with the quiescent stages of volcanic action. It consists essentially of a tube extending downwards to a zone of high temperature, and connected with some source of water supply. The water in the lower part of the tube becomes gradually heated above the boiling point, until sufficient force accumulates to expel the whole column, which is usually done with explosive violence. The thermal waters commonly leave a deposit of Geyserite around the orifice.

Geyserite (*Min.*) *See* SINTER.

Giallolino (*Paint.*) *See* NAPLES YELLOW.

Gib (*Eng.*) A bar of metal with its ends bent at right angles to its length; used with a cottar or wedge for holding in place the loose strap on the end of certain forms of connecting rod.

Gibbous (*Astron.*) The apparent form of the visible portion of a planet or satellite when more than half but less than the whole illuminated hemisphere is seen.

Gib Headed Key (*Eng.*) A key with one end bent at right angles to its length (similar to a gib),

Giffard's Injector (*Eng.*) A device for forcing a small stream of water into a boiler against the pressure of the water and steam. The necessary energy is supplied by a small jet of steam at a high velocity. The apparatus can be made continuous in action, and has the advantage of possessing no moving parts.

Giggering (*Binding.*) Sliding a line finishing tool (fillet or pallet), in place of working it over the leather. It adds brightness to the gilding.

Gigging (*Woollen Manufac.*) A process of raising on the RAISING GIG (*q.v.*) Applied to certain types of woollen fabrics, rugs, and blankets.

Gilding. *See* ELECTROPLATING, GOLD LEAF, GOLD PAINTS, GLASS MANUFACTURE.

Gimlet (*Carp., etc.*) The ordinary boring tool used for making small holes in wood. The best forms have a helical (or so-called "spiral") fluting running round the shank or stem.

Gimp. A kind of openwork trimming formed of worsted, cotton, or silk twist, with generally a thin wire or cord running through. It is used on dress, furniture, etc.; that used on dress is sometimes covered with beads.

Gin. A form of trap actuated by a spring; used for catching game or vermin.

—— Prepared from the distillation of fermented grain, flavoured with juniper berries and other aromatic substances. The amount of alcohol present is about 45 per cent. The limit to which the spirit can be reduced by the admixture of water under the Food and Drugs Act is 35° under proof.

Gin (*Eng., etc.*) A simple form of hoisting machine; the hoisting rope or chain is wound on a barrel driven by a handle, without any gearing.

——, Cotton (*Cotton Manufac.*) *See* COTTON GIN.

Ginger (*Botany*). The dried rootstocks of the plant *Zingiber officinale* (order, *Zingiberaceæ*) are known to commerce in two forms, the "coated" and the "scraped," according to whether the rind is retained or not.

Gingham (*Cotton Manufac.*) A plain weave of cloth, medium to heavy make, usually of fine warp threads and coarser weft. Generally made in check patterns.

Ginseng (*Botany*). The root of *Aralia Ginseng* (order, *Araliaceæ*) has been long esteemed as a medicine in China. It is also used as an adulterant of senega root.

Girandole (*Furniture, etc.*) (1) Candelabra. (2) Revolving jets of water, as on an ornamental fountain. (3) A pendant or earring.

Girder (*Eng., etc.*) A beam of iron or steel. It may be in one piece, produced by casting or by rolling, or may be built up of a number of plates or bars of wrought iron or mild steel, riveted or bolted together. The latter form is the one now most commonly adopted. The name is also applied to a built up beam of wood and iron, *e.g.* a FLITCH BEAM (*q.v.*)

Girder Bridges (*Eng.*) Bridges carried by girders alone; used where the span is not too great, or where intermediate piers can be erected.

Girth. The circumference of an object.

Girth Measurement (*Dec.*) In estimating the area of painted work or plastering, mouldings are measured round each member by a flexible tape.

Git (*Foundry*). A GATE (*q.v.*)

Give (*Eng., etc.*) A joint or a structure is said to "give" when it yields or breaks under a load.

Gjer's Kiln (*Met.*) A circular kiln of iron plates lined with firebricks and having an inverted cone at the bottom. Used for calcining iron ores for the blast surface; chiefly in the Cleveland district. The same patentee is associated with a pneumatic lift for blast furnaces, and "soaking" pits (*q.v.*) for steel blooms.

Glacé (*Silk Manufac.*) A very closely woven plain silk, thin and bright; tie as tabby.

Glacé Kid (*Leather Manufac.*) Goat skins prepared with high glaze. Originally alum tannage was employed; now chiefly chrome tanned. Properties: very strong, pliable, and light; used for uppers of light boots and shoes. *See* GLAZING.

Glacial Acetic Acid (*Chem.*) A name given to the purest commercially prepared acetic acid; so called because it solidifies to an ice-like mass, which melts at about 16° C. *See* ACETIC ACID.

Glacial Action (*Geol.*) In general terms this may be said to give rise to three sets of results: (1) The transportal of rock débris downhill and seaward from the heart of a mountain area; (2) the mechanical erosion of the sides and the floor of the rocky surface over which the ice is moving; (3) the redeposition of the transported débris in the form of morainic matter, or, in the case of the larger masses of ice, in the form of boulder clay, or more or less

waterworn materials which form ESKERS and other deposits of sand and gravel. *See also* MORAINES.

Glacial Denudation (*Geol.*) *See* DENUDATION.

Glaciation (*Geol.*) *See* GLACIAL ACTION.

Glacier (*Geol.*) Elongated and river-like masses of ice, due to the regelation of half-melted snow and the gradual flow of the resulting semi-solid downhill and seawards along some pre-existent valley shaped by rain and rivers. Glaciers grow only under those geographical conditions in which more snow falls than the summer's heat suffices to melt. Glaciers are important agents in modifying the form of the surface over which they move. Most of the British lakes, for example, are old river valleys which have been locally deepened and widened by the erosive action of glacier ice in former times.

Glaire (*Binding*). White of egg well frothed up, with the addition of a drop or two of vinegar. It is applied to the places which are to be gilded to ensure the adherence of the leaf gold.

Glaive (*Arms*). The name glaive has been applied at different times to different weapons—*e.g.* to the bill, the spear, and the sword. More commonly it refers to the bill (*q.v.*)

Gland (*Biol.*) Certain organs in an animal or plant which secrete fluids having special functions; *e.g.* salivary gland, lachrymal gland, mammary gland, etc.

—— (*Eng.*) The tubular casting which fits into the stuffing box (*q.v.*) of a cylinder, etc., and through which the piston rod slides.

Gland Bolts (*Eng.*) The bolts which hold a gland in place.

Glass Embossing (*Dec.*) Although this work constitutes a trade in itself, it is often carried on in conjunction with sign writing. The process consists of etching a design on the surface of glass by means of hydrofluoric or white (sometimes called French) acid, or a combination of both. The design is usually drawn upon cartridge or manilla paper, and is pounced (*q.v.*) on the face of the glass. A coat of Brunswick black, sometimes mixed with a little beeswax, is then painted over those portions of the surface that are not to be etched. When the black is quite dry, a little wall or embankment made from a mixture of tallow and Burgundy pitch is placed around the edge of the glass to confine the acid. Care being taken that the surface is quite level, the acid is gently poured on, and immediately begins to eat into the glass, the black protecting those parts which it covers. When the etching is sufficiently deep, the acid is poured back into the guttapercha bottle in which it is kept for further use, and the black is removed by softening with turpentine and scraping off. Hydrofluoric acid gives a different surface from French acid, and the two are therefore frequently used one after the other to produce shaded effects. The process is often used on flashed glass such as ruby, the acid removing the coloured surface, and leaving the design or lettering in white upon the ruby ground.

Glassmakers' Soap (*Glass Manufac.*) Manganese dioxide, which, when added to the "metal," removes the green colour due to ferrous silicate.

Glass Manufacture. The discovery of the art of making glass is lost in antiquity. Probably the ancient priests of Egypt were the first to practise its manufacture. At Memphis and Beni-Hassan are to be found, sculptured on the walls of the tombs, unmistakable representations of glass blowers at work. These date from 3900 and 2851 B.C. respectively. The oldest piece of glass known was found at Thebes by Signor Drovetti. It dates from 3064 B.C., is opaque blue in colour, and is now in the British Museum. The early Egyptians used glass to form hieroglyphics for inlaying in stone, wood, or metal, and for personal ornamentation; many examples of these may also be seen in the British Museum. Perhaps the earliest proof of the DOMESTIC USE OF GLASS is found in the frescoes of Thebes, where glass bottles holding wine are represented (1500 B.C.) That the practice of moulding glass was known at that date is apparent by their figures and ornaments, which have every indication of being cast. The colours chiefly employed were opaque dark blue, turquoise, yellow, and white. Both in the British Museum and in the Victoria and Albert Museum can be seen many beautiful specimens of glassware, upon which all these colours are to be found. They consist of small vase-like forms with and without bases and handles; canes or threads of the various colours appear to have been placed around the body in alternate horizontal bands while in the molten state, and at equal distances round the article these circular threads have been pulled together in an upward direction, probably by means of a hook (a method still in use at the present day), producing catenary-like curves, while in others the partial displacement of these undulating bands of different colours is so regular as to suggest the use of a machine. The Phœnicians, Greeks, and early Romans manufactured glass closely resembling that of Egypt, indicating that they obtained their knowledge of glassmaking from the Egyptians, or perhaps employed Egyptian glass workers. The Romans of the later period made glass in great variety of colours and designs, imitating all kinds of gems and stones, and using various opaque colours for decorative purposes. They also practised many methods of casing, or flashing various colours one on another, thus producing what is known as SCULPTURED or CAMEO GLASS. This is made by coating a dark blue opaque glass with a white opaque glass whilst in the molten state, and so uniting them together. It is then blown out into the required shape, and, after being annealed, the portions of the white coatings which form the design are carved, while those not required are removed, thus exposing the dark blue ground. The PORTLAND VASE (British Museum) is a notable example of this style. So remarkable is the knowledge displayed in its manufacture, the elegance of its form, and the expressive modelling of the figures which form the design, that it is regarded as the most magnificent gem of the glassmakers' art extant. The Venetian glass blowers were artists of considerable skill, and introduced many varieties of glassware, elegant in shape and of extraordinary lightness. For a long period Venice excelled all Europe for the beauty of its glass. Venetians revived the art of glass mosaic and window glass painting. They also produced many ingenious designs in ornamental and domestic articles by the use of canes or threads, in white opaque glass, arranged in various patterns, thus producing their LATICINIO, VITRO-DI-TRINA, and PRETICELLI WARE in great variety, examples of which can be seen in the British Museum. AVANTURINE was also invented by the Venetians. This is a soda-lime glass containing copper in a state of reduction, which forms spangles of metallic copper throughout the mass; its manufacture has for a long time been kept a secret, and it is still made at Venice.

The art of glassmaking was carried to the western countries of Europe first by the Romans and later by the Venetians. In the year 1557 Venetian glasses were made at Crutched Friars in London, although at a much earlier period glass of an inferior quality was evidently made in England.

Constituents of Glass.—SILICA, commercially known as sand, is the essential constituent of all glass, and, together with certain metallic oxides, forms by the application of intense heat an amorphous transparent body, every true glass containing at least two metallic oxides. The oxides chiefly used are those of Lead, Potassium, Sodium, Calcium, Barium, Aluminium, and Magnesium. To produce effects of colour the oxides of the following metals are employed, but if used in excess they produce opacity:—*Black:* oxides of manganese and iron. *White:* the oxides of arsenic, tin, and calcium; calcium phosphate, fluorspar, and cryolite. *Yellow:* oxides of cadmium and uranium. *Blue:* cobalt. *Green:* chromium. Different oxides of the same metals are in some cases capable of producing different effects of colour. Iron in the *ferric* state gives a yellow colour, but when present as *ferrous* oxide it gives a bottle-green colour. Manganese dioxide gives a violet colour, whereas the monoxide does not colour glass. Cupric oxide in small quantities gives a *Peacock Blue*, which is converted into *Green* if the quantity of oxide is increased; but from cuprous oxide a rich *Ruby* coloured glass is obtained: this colour is also obtained by using gold. Ruby glass prepared from these metals is colourless when taken from the crucible or pot in which it is made. After being allowed to cool, the ruby colour appears upon reheating. If at this stage the glass be exposed to a high temperature for too long, the ruby colour obtained from gold disappears, and is replaced by a dull brown. By the action of silica at a high temperature it is found that the oxides, carbonates, and sulphates of the metals are decomposed, evolving carbonic anhydride and sulphurous anhydride, and forming silicates of the different metallic oxides, which vary in quality according to the different proportions employed. When two or more substances containing different metallic oxides are fused together with sand, the result will be a mixture of the silicates of the oxides present. *Glass is therefore regarded as a mixture and not a chemical compound.* FLINT or LEAD GLASS is a mixture of the silicates of lead and potassium; BOHEMIAN, of those of potassium and calcium; PLATE and SHEET GLASS, of calcium and sodium; BOTTLE GLASS, of silicates of sodium, aluminium, and calcium; VENETIAN, of sodium, potassium, and calcium. After the ingredients for making glass are thoroughly mixed and put into the pots within the furnace, decomposition of the raw materials takes place, with the expulsion of the gases, and the silica and the metallic oxides combine; the glass passes into the liquid state and remains in this condition so long as the full heat of the furnace is maintained, but if the heat be slightly reduced or the glass exposed to the air, it passes into a state of ductility or viscosity. In the liquid state it can be ladled or poured direct from the crucible for pressed articles and rolled plate. In the viscous condition it can be gathered on the heated end of an iron rod, which, if hollow, enables the mass of glass so collected to be blown into any required shape. By gravitation it can be flattened or elongated, and, by using moulds, made to take any required form. It is also capable of being drawn out into fine threads and tubes.

The manufacture of glass may be divided into two heads: Hollow Ware and Flat Ware. HOLLOW WARE comprises blown glass, bottle glass, blown glass tube, lampwork, and pressed glass. FLAT WARE comprises crown and sheet glass, mosaic glass for windows, plate and optical glass. The BLOWING IRON or hollow iron rod used in the manufacture of hollow ware is from 5 to 6 ft. in length and from ¾ to 2 in. in diameter. The workman gathers upon the heated end of this sufficient glass for making the required article, and by rolling it upon a polished plate of iron (called a MARVER) consolidates and centres the molten mass upon it. The glass is then expanded into a bulb by blowing down the tube: the first stage of manufacture of all glass of this description. By swinging, the bulb is lengthened; and by the aid of a flat square of polished iron with a wooden handle (BATTLEDORE) the end of the bulb can be flattened. Should a stem and foot be required, as in a wine glass, it is either formed out of the end of the bulb which is farthest from the iron, or by the addition of another portion of glass dropped upon the bulb. If the stem is of a fancy shape, it is made separately and attached to the bulb. The foot, if blown, is then made in the form of a circular bulb and attached to the stem, being afterwards heated and opened out. A foot can also be cast on. In this case sufficient glass is allowed to adhere to the end of the stem, and by using two pieces of wood hinged together the workman compresses the soft glass between the open boards and at the same time rapidly rotates the blowing iron upon the arms of his chair, thus causing the glass to assume the proper form. At this stage the body of the article (the bulb) can be covered with fine threads of plain or coloured glass, or decorated with ornamental pinchings. In the primitive stage glass can be blown into any shape by the use of moulds, which are made of wood, carbon, or iron; and its surface can also be impressed with any pattern by the use of dip moulds. If the article requires a handle and foot (*e.g.* a claret jug) the bulb or body is blown to dimensions and correct form and the foot attached as previously explained. The workman then takes the WORKING IRON (a solid rod), on which has been gathered a small portion of molten glass, and fixes it to the centre of the foot; by applying a chilled iron at a point close to the blowing iron, and by giving it a sharp tap, the article is severed from the blowing iron and adheres to the working rod. After reheating what is now the opening or top of the article, the surplus metal is sheared or cut off, and the workman proceeds to form the lip or spout. A portion of molten glass is next gathered to form the handle, which may be either solid or hollow. After being marvered and made to take the form of a circular rod, it is reheated and taken to the maker, who, while holding it in a vertical position, presses down the end of the molten rod of glass upon the body of the jug, so as to form a good connection or sticking; he then pulls away the iron, reduces the thickness of the handle, and cuts it off with the shears to the proper length. The disconnected end is then turned up by means of a small pair of tools, and fastened to the top portion of the article, thus forming the handle. After reheating the jug, so that the whole shall be of an even temperature, it is severed from the working rod and carried to the LEAR, or annealing oven, placed near the source of heat, and gradually removed from it, thus allowing the glass to become annealed. The simplest and oldest arrangement for annealing is a tunnel 30 ft. in length, either heated

at one end by fires on both sides of the lear, or by waste heat from the melting furnace. The goods are placed in pans attached to each other by means of hooks, thus forming a continuous train, which is moved by means of a chain and windlass. The claret jug now passes to the decorator, and if required can be either cut, engraved, etched, enamelled and gilt, or carved. CUTTING: After the design (which usually consists of lines arranged upon a geometrical basis) has been marked or drawn upon the article, it is first "roughed out." This is done by pressing the glass against the edge of an iron wheel revolving in a vertical plane, upon which is allowed to run sand and water from a hopper or container suitably adjusted, the sand cutting its way into the surface; the rough incisions are smoothed by stone wheels supplied with a constant flow of water. These latter range from 3 to 24 in. in diameter, and have cutting edges of different forms, so as to produce a variety of cuts. The pattern is then polished, to regain the transparent brilliancy of the glass, either by wooden (willow wood) wheels or by a rapidly revolving brush, using as a medium pumice powder and rottenstone, and finally putty powder. The last named is a substance obtained by fusing together lead, tin, and antimony. As the oxide forms upon the top of the molten mass it is collected, pounded, and sieved; it is then ready for use, and is found to be the best medium for polishing lead glass; but for polishing lime glass, rouge (oxide of iron) is generally used. ENGRAVING is done by wheels of copper varying from 2 or 3 in. to $\frac{1}{8}$ in. in diameter. These are fastened to the end of a spindle attached to a small lathe, which is generally driven by a foot treadle. The engraving medium used is emery powder and oil; for polishing, rouge or pumice and oil are used, with lead, wood, or cork wheels. The engraver produces a more elaborate design than the cutter, as the work is held underneath the wheel, while in cutting, the article is usually held in a direct line between the workman and his wheel, he having to look through it in order to follow the pattern. This gives the advantage to the engraver, whose work, although not so deeply incised, is capable of greater refinement of form and contour than the cutter's, which is generally stiff and formal. An engraved design can be either left rough from the wheel, partly rough and polished, or, (as in the case of designs which imitate rock crystal) after being more deeply engraved, the design can be polished all over. A style of decoration which has been practised to some extent in recent years is produced by cutting with small stone wheels. It is somewhat similar to the process of engraving, and is very effective. ETCHING consists in the erosion or eating away of the surface of glass by hydrofluoric acid. Patterns are produced by covering the whole surface of the glass with a thin coating of wax, or RESIST, removing those parts intended to be etched, and plunging the article into a solution of the acid. In order to produce a geometrical design, the wax can be removed by the use of a lathe (similar in construction to that employed in turning a rose pattern on wood or metal). The pattern can also be etched down or engraved on copper plate filled in with resist, and transferred to the article; or a lithographer's stone can be used as a means of producing a quantity of transfers of the same design. SAND BLASTING is another method of producing an etched effect upon glass, the parts which are to remain smooth being protected by a stencil of paper or some other clinging material. PAINTING, GILDING, *and* SILVERING are fixed by heat. For painting, white and coloured enamels are used as colours; and an amalgam of gold or platinum, or the powders of the same metals reduced from solutions, are used for gilding and silvering. The enamels are specially prepared so as to fuse at a lower temperature than the article to be decorated; they are applied by means of a brush, and fixed by heating in a muffle furnace. CARVING (CAMEO GLASS): This consists of two or more casings of opaque white and coloured layers of glass one above the other. The design is painted on with resist, and the portions of the surface not required are etched away by hydrofluoric acid. The roughly formed design is then engraved, and finally carved with small tempered steel tools by hand. The ground or background of the design may be polished or left with a matted surface. BOTTLE GLASS: Owing to the presence of ferric oxide in the cheap materials employed in the manufacture of bottles, they are generally of a greenish tint, this being due to the ferric oxide, upon heating, becoming converted into the ferrous oxide; by adding small quantities of manganic oxide and oxide of cobalt to the materials used, an orange or a blue colour is obtained. The furnaces generally in use are of the continuous tank type, the raw materials being put in at one end and the molten glass withdrawn from the other. Bottles are blown in moulds made of brass or iron, which, whilst being used, must be maintained at nearly a red heat. A mould for a cylindrical vessel may be in one piece, but must widen slightly towards the bottom to permit the glass to be removed from it. Bottles having names or markings upon the surface must be blown in moulds which consist of two or three portions. The simplest form of such moulds is in two parts, hinged at the bottom. The gatherer, having collected sufficient glass on the blowing iron, passes it over to the blower, who, having slightly expanded the bulb by blowing down the iron, marvers it until it assumes a conical form. He then inserts the bulb of molten glass into the mould, which he closes with his foot; by blowing down the iron he forces the bulb to take, both *externally* and *internally*, the internal form of the mould. He opens the mould, and removes the bottle attached to the blowing iron. After having "wetted it off" by applying a moistened tool to the neck, it is handed to the workman who fashions the lip by coiling a small piece of molten glass round the neck, and by the aid of a special tool, which he inserts in the neck of the bottle, forms and finishes the lip. The bottle is then taken to the annealing kiln, which, when completely filled, is allowed to cool. PRESSED GLASS: The cheaper articles for domestic use are not made by hand, but by the use of lever and screw presses and stoutly made moulds. The molten glass takes the form of the mould upon its outer surface, while the inner surface is formed by a metallic plunger. The base, body or collar, and top of the mould, in which the plunger fits, are all accurately fitted and hinged together. The mould is firmly fixed upon the table of the press immediately underneath the plunger, which is attached to the end of a screw. By the aid of a fixed crossbar working in vertical slides, movement is obtained by revolving a flywheel, which is rigidly connected to the screw. This causes the plunger to descend with considerable force, and at once presses the molten glass into the shape of the mould. Pressed glass always requires to be polished by reheating the outer surface, to take away the roughness caused by the chilling action of the mould. CROWN *and* SHEET GLASS: The oldest

method of manufacturing glass for glazing purposes in this country is that known as crown glass making. The workman having gathered sufficient glass from the pot, marvers it, or gives it a conical form by turning it in a block of wood or metal, hollowed out to the required shape—the apex of the cone forming the BULLION POINT. The glass is now slightly expanded, reheated, and blown until it assumes the shape of a huge decanter having a flat bottom and a very short neck. A PONTY, or working rod, is attached to the bullion point, and the form severed from the blowing iron. The workman standing in front of the furnace, with a veil before his face, reheats the form; by rapidly revolving the iron the glass expands into a thin transparent circular plate. This plate, now called a TABLE, usually about 54 in. in diameter, is detached by shears from the ponty and lifted into the annealing kiln upon a fork. The cutting up of the circular table of glass in rectangular sheets causes much waste, and the bull's eye in the centre confines the sheets to rather small sizes as compared with those made by the cylindrical method. SHEET GLASS, in its preliminary stage, is made similarly to crown glass, being formed in hollow blocks of wood or metal; but it is expanded by the blower to the diameter ultimately required. The block, if of wood, is sprinkled with water to prevent it from burning, and to prevent scratching of the glass. A hollow iron block, through which water is allowed to pass to keep it cool, is sometimes used, the surface of the block being covered with charcoal to prevent scratches. The blower, after having reheated the bulb of molten glass, stands over a pit, or well, some 10 ft. deep, and swings the bulb round in a vertical plane, and also backwards and forwards, until the mass expands into a huge cylinder of the required length, the diameter being determined by the block, and remaining the same throughout. The cylinder is opened at the end remote from the iron. Thin ones are opened by forcing in air through the pipe and stopping up the aperture. Upon reheating the end, the expansion of the air within the cylinder causes it to burst open. The opening is then widened out to the size of the cylinder by swinging to and fro, with the opening downwards. The thicker kinds are opened by attaching a lump of hot glass to the end; air is forced in and the cylinder burst open, the opening being enlarged by cutting with scissors. The cylinder is then placed upon a wooden rest and detached from the blowing iron by wrapping round it a thread of hot glass. This is quickly removed, and upon a cold iron being placed against the part previously covered by the hot thread, the end which was attached to the blowing iron breaks away. The cylinder is then split longitudinally along the inside by a diamond attached to a long handle guided by a wooden rule. It is now taken to the flattener, who, after warming it in his furnace, places it with the split uppermost upon the flattening stone, upon which is placed a sheet of glass called a LAGRE. The heat of the furnace causes the cylinder to open out, and the flattener rubs down the wavy sheet into a flat surface with a POLISSOIR (a rod of iron with a block of wood at one end). The sheet is afterwards removed to a cool part of the furnace and allowed to anneal. PATENT PLATE is sheet glass specially selected, and ground and polished by machinery. The average sizes of sheets are 48 × 34 to 36 in., but by the assistance of a mechanical arrangement (called the IRON MAN) sheets are made up to 82 × 42 in. PLATE GLASS is manufactured by pouring the molten glass from the pot (taken from the furnace) upon a smooth, flat iron table some 30 to 40 ft. long by 15 to 20 ft. broad, and by passing a smooth parallel iron roller of cast iron, some 2 ft. in diameter and weighing many tons, backwards and forwards over the surface of the molten mass, by men hauling upon tackle attached to the ends. The glass is rolled into rough plate, the thickness of which is determined by strips of iron placed upon the table, and upon which the ends of the roller bear, the distance apart of these strips determining the width of the plate. The plate being "cast," it is thrust from the table into the annealing oven, which is closed up and allowed to cool. The rough plates are used for lighting purposes; if required for mirrors, etc., they are ground and polished. To effect this the plate is first bedded in plaster of Paris upon a revolving table, and cast iron rubbing plates are laid upon it, each having a central pivot or pin which works in the eyes of two fixed radial rods carried to cast iron standards erected outside the revolving table. Sand and water are allowed to flow upon the plate, and the surface is ground flat. The grinding process is completed by the use of powdered emery. The plate is turned over and the process repeated. The plate is next smoothed by bedding it upon another table or machine, but instead of iron plates, sheets of glass are used for rubbing, with finely powdered emery and water as a medium, beginning with the coarsest grain and finally finishing off by hand, using wood blocks with flour emery and water. Polishing is performed on another machine, the table having an alternating sideway motion at a slow speed under a pair of arms moving at a high speed and at right angles to that of the table. Upon the arms, at intervals of 12 in., weighted spindles are placed, at the bottom of which are discs of wood capped with felt; these are put upon the surface of the plate which is bedded upon the table. Rouge and water are squirted upon the glass with syringes, and the surface polished. Both sides of the plate are treated in this way. These plates vary in thickness from $\frac{3}{8}$ to $\frac{5}{8}$ in., and are cut up into required sizes with a diamond. Plate glass used for mirrors and windows can be decorated by etching, engraving, and light cut patterns. G. J. C.

Glass, Natural (*Geol.*) Volcanic products, due to the rapid cooling of a fluid mass of rock from its initial high temperature. OBSIDIAN is a natural glass, having about the same composition as that of granite. Many pitchstones bear the same relation to syenite, while the native glass known as TACHYLITE is the glassy representative of the gabbros, dolerites, and basalts.

Glass Paper *or* **Cloth.** Sheets of tough paper or a thin fabric, the surface of which is covered with finely crushed glass (caused to adhere by glue). Used for smoothing surfaces of wood, etc. *See also* SANDPAPER.

Glass Papering Machines (*Joinery, etc.*) Machines which give rapid rotation to a disc or roller covered with glasspaper; this can be brought in contact with the surface of woodwork requiring to be glass papered.

Glass, Soluble. *See* SOLUBLE GLASS.

Glassy Felspar (*Min.*) A variety of ORTHOCLASE (*q.v.*) occurring in vitreous crystals in volcanic rocks.

Glauberite (*Min.*) Calcium sodium sulphate, $CaNa_2(SO_4)_2$; monosymmetric. Occurs in association with gypsum, rock salt, borax, etc.

Glauber Salt (*Min.*) A synonym for MIRABILITE (*q.v.*)

Glauber's Salt (*Chem.*), $Na_2SO_4 10H_2O$. Sodium sulphate crystallised below 34° C., when it crystallises with ten molecules of water of crystallisation. *See* SODIUM COMPOUNDS.

Glauconite (*Min.*) A hydrous silicate of iron and potassium of somewhat variable composition. It occurs in small grains of a greyish or olive green colour in the Greensand and some other rocks. It is not known crystallised.

Glaze (*Pot.*) Glaze is that which forms the gloss or smooth transparent surface on pottery or porcelain. It may be either colourless or coloured. Generally composed of an admixture of alkalis with silica, lime, and often oxide or carbonate of lead. A glaze is said to be "hard" if it requires a great heat to melt it, and "soft" if it is melted at a low temperature. *See* HARD PASTE.

Glazed (*Build.*) Filled in with glass.

Glazed Boards. Millboards that have been subjected to great pressure. Printed sheets are sometimes placed between glazed boards in a press to impart a more finished appearance.

Glazed Brick (*Build*). A brick used for facing, having a glazed surface.

Glazed Frost (*Meteorol.*) When damp air at the beginning of a thaw comes into contact with very cold ground, a thin sheet of ice is sometimes formed. Rain or a warm wind coming suddenly after a frost will sometimes produce this effect.

Glazing (*Eng., etc.*) The clogging of the surface of a grindstone by the material removed from the metal which is being ground.

—— (*Leather Manufac.*) A process by which a high gloss is given to leather. The skin to be glazed is coated over with a solution of albumen, and glazed when dry by a glazing machine. Calf boot leather is glazed by brushing with a solution of wax and soap, and polishing with brush or cloth.

—— (*Plumb.*) Going over a wiped joint with a hot iron, in order to produce a finished surface.

Glazing Colour (*Dec.*) A transparent colour used over a comparatively dull ground to increase its brilliancy: thus, when a very bright green is required, a light green is glazed over with emerald green (*q.v.*), which has very little body (*q.v.*) The madder lakes are often used to enrich the effect of red grounds.

Globigerina Ooze *or* **Foraminiferal Ooze** (*Geol.*) An accumulation of the calcareous shells of various kinds of foraminifera which gathers on the ocean floor at considerable depths, and which prevails there over a large area of the Earth's surface. In past times deposits of essentially the same nature have given rise to considerable groups of strata, some of which form important geographical features.

Globular Lightning (*Meteorol.*) An electrical phenomenon whose nature is not understood: an appearance resembling a globe of fire, sometimes visible for a number of seconds, is produced.

Globular Structure (*Geol.*) A general term which is applied indifferently to such cases as those where concretions have grown into ball-like masses; to the spheroidal structures developed in some vitreous rocks; and to the bomblike forms assumed by some basalt or andesite lavas in cases where they have flowed into water.

Globulins (*Chem.*) A class of proteid substances very similar to the albumins, but differing from them in being insoluble (or very difficultly soluble) in water, soluble in dilute salt solutions from which they are precipitated on further dilution or removal of the salt by dialysis, insoluble in saturated solutions of sodium chloride and magnesium sulphate, insoluble in half saturated ammonium sulphate solutions. They are precipitated from their solutions by dilute acids. After being precipitated by acids or by removal of salt by dialysis, they quickly become insoluble. Some of them are acids, having an acid reaction to litmus. Examples of globulins are serum globulin, cell globulin, crystallin (in the crystalline lens of the eye).

Glockenspiel (*Music*). *See* MUSICAL INSTRUMENTS—PERCUSSION (DEFINITE SOUND).

Glory (*Art*). *See* AUREOLA.

—— (*Meteorol.*) *See* FOG IMAGE.

Glory Hole (*Glass Manufac.*) *See* FURNACES (GLASS).

Gloss (*Dec.*) Fine oil paint is an important indication of the proper mixing and good quality of the ingredients. If good linseed oil is used, the paint will always show a good gloss. A little varnish is often added to paint to increase the gloss; but if too much is used the paint is likely to "curdle." Some painted work is finished entirely without gloss. *See* FLATTING MATT.

Glost Oven (*Pot.*) After the bisque ware has been dipped in the glaze it is fired in the GLOST OVEN to melt the glaze. *See* BISQUE *and* ENAMEL KILN.

Glove Leather (*Leather Manufac.*) Made from lamb and kid skins. The leather is prepared by a tannage or tawing process, the ingredients consisting of alum, salt, flour, and egg yolk, mixed to a paste with water. The paste is got into the skins either by TREADING (France and Germany) or by DRUMMING in large revolving drum (England). *See* DRUMMING.

Glover Tower (*Chem. Eng.*) A reaction tower placed between the pyrites-burners and vitriol chamber in the manufacture of sulphuric acid. The hot sulphur dioxide from the burners passes up the tower and decomposes the nitrosulphuric acid from the GAY LUSSAC TOWER (*q.v.*), carrying the nitro compounds forward into the chambers.

Glow (*Met.*) Sky glow accompanies the rising and setting of the sun, and is due to the diffraction and reflection of light by the minute particles in the air. Magnificent coloured glows usually accompany large volcanic outbursts.

—— **Counter** (*Astron.*) *See* GEGENSHEIN.

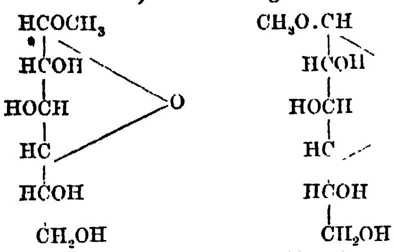
Glucinum (*Chem.*) BERYLLIUM (*q.v.*)

Gluconic Acid (*Chem.*), $CH_2OH.(CHOH)_4.COOH$. A syrupy liquid which readily passes into its lactone (*see* LACTONES); a crystalline solid. It is dextrorotatory; its lævo and inactive forms are known. It is obtained by heating dextromannonic acid with quinoline; also by oxidation of dextrose with bromine water. On reduction it yields dextrose. It is very important in the synthesis of dextrose (*q.v.*) and lævulose.

Glucosazone (*Chem.*) *See* OSAZONES.

Glucose (*Chem.*) Another name for DEXTROSE (*q.v.*)

Glucosides (*Chem.*) Are ether derivatives of glucose. Many glucosides which occur naturally are very important substances; they are resolved by enzymes (*q.v.*) and by dilute acids and alkalis into glucose, and the other substances united with it in the glucosides. For examples of glucosides *see* AMYGDALIN, SALICIN. The simplest glucoside is methyl glucoside, which is prepared by the action of hydrochloric acid on glucose dissolved in methyl alcohol. It exists in two stereoisomeric (*see* STEREOISOMERISM) forms having the formulæ:



α-Methyl Glucoside. *β*-Methyl Glucoside.

The enzyme invertase hydrolyses the *α* form, but not the *β* form; while emulsin hydrolyses the *β* form, but not the *α* form. The natural glucosides are hydrolysed by emulsin just as *β*-methyl glucoside is. As invertase can only split 1 molecule of glucose from the amygdalin molecule, while emulsin can split off 2 molecules, it is concluded that amygdalin (*q.v.*) contains the two glucose molecules in the form of maltose (*q.v.*)

Glucosone (*Chem.*) *See* OSAZONES.

Glue. An impure form of gelatine made from bones, skin, and animal refuse generally. The colour and quality vary considerably, according to the material from which the glue is manufactured. Good glue is wholly insoluble in cold water, but absorbs a quantity when immersed, sometimes as much as four times its weight. There are many processes of glue making, but they all consist of digesting the bones or hides, clarifying the gelatinous liquor, and running into moulds. The jelly is then cut up into slices, which are placed on nets in a stove to dry. *See* SIZE.

Glue Pot. Glue is usually melted in a vessel surrounded by an outer vessel which forms a water bath. This subjects the contents to a steady temperature not exceeding 212° F.; and the hot water in the outer vessel serves to retain the heat when the pot is removed from the stove for use.

Gluing (*Carp., etc.*) Gluing consists essentially in filling the interstices between two surfaces of wood (or other material) with a *thin* layer of glue. All superfluous glue should be expelled by squeezing (or by rubbing the surfaces together when possible).

Glume (*Botany*). The two scales at the base of the spikelet in the inflorescence of a grass.

Glutaminic Acid (*Chem.*), *α*-Aminoglutaric acid, $COOH.CH_2CH_2CHNH_2COOH$., is a decomposition product of albumin on boiling with hydrochloric acid: it is also widespread in the vegetable kingdom. Forms shining octahedra; soluble in hot water. It is dextrorotatory.

Glutaric Acid (*Chem.*), $COOH.CH_2.CH_2.CH_2.COOH$. Forms shining prisms very soluble in water; melts at 97°. It forms a characteristic zinc salt. It occurs in wool fat and in turnip juice. It may be obtained from sodium malonic ester (*see* MALONIC ACID) by action of methylene iodide:

$$2\,CHNa(COOC_2H_5)_2 + CH_2I_2 = CH_2\begin{cases}CH(COOC_2H_5)_2\\ CH(COOC_2H_5)_2\end{cases} + 2NaI$$

On saponifying this ester and heating the product, it yields glutaric acid. The acid is also produced by treating dihydroresorcin with sodium hypobromite—an example of change from a benzene ring compound to a fatty compound. On slow distillation it yields an anhydride which yields an IMIDE, $CH_2\begin{cases}CH_2.CO\\ CH_2.CO\end{cases}NH$, with ammonia: this amide is produced by oxidation of PIPERIDINE with hydrogen peroxide. DIMETHYLGLUTARIC ACID, $COOH.CH_2CH_2.C(CH_3)_2.COOH$, is an oxidation product of camphor.

Gluten (*Chem.*) The substance obtained when flour is made into dough and the latter washed free from starch by water. It is not present in flour, but is generated from the flour proteids by the above treatment. When moist, it is a yellowish grey sticky mass; on account of its tenacity it retains the carbonic acid in dough when yeast is added or carbon dioxide is passed into it, thus making bread light. Gluten is not a single substance; next to nothing is known of its chemistry. *See* BREAD.

Glutin (*Chem.*) Another name for GELATINE (*q.v.*)

Glyceric Acid (*Chem.*), $CH_2OH.CHOH.COOH$. A syrupy liquid soluble in water and alcohol. It contains an asymmetric carbon atom (*q.v.*) (the middle one); and the inactive acid can be resolved into its two components—*Penicillium glaucum* destroying the ammonium salt of the dextrorotatory variety and leaving the lævorotatory salt, while the *Bacillus ethaceticus* destroys the lævorotatory acid only. The inactive acid is obtained from glycerine by oxidation with dilute nitric acid.

Glycerine (*Chem.*), $CH_2OH.CHOH.CH_2OH$. A colourless, odourless, viscous liquid with sweet taste. Boils at 290° C.; it is about a quarter as heavy again as water; burns with pale blue flame; is very hygroscopic, readily absorbing moisture from the air. It mixes with water and alcohol in every proportion, but it is insoluble in ether, benzene, chloroform, carbon disulphide. It is a very powerful solvent, dissolving many salts just as water does; it also dissolves many metallic oxides, *e.g.* lead oxide. It is a constant product of the alcoholic fermentation of sugar. In nature it occurs combined with the "fatty acids" in fats (*q.v.*) It is prepared on an enormous scale as a by-product in the preparation of fatty acids for candle making, and in the manufacture of soaps. In the first case the fat is resolved into fatty acid and glycerine by treatment with superheated steam in presence of a little lime; in the second case by boiling with caustic soda or potash, and the glycerine is purified by processes too complex to be given here. The following are important reactions of glycerine: (1) Heated with sulphuric acid or potassium hydrogen sulphate it gives acrolein (*q.v.*); (2) with amorphous phosphorus and iodine it gives allyl iodide, isopropyl iodide, and propylene; (3) oxidised by dilute nitric acid it gives glyceric acid (*q.v.*); (4) with bromine water it gives GLYCEROSE, a mixture of the aldehyde $CH_2OHCHOHCHO$ and

Ketone $CH_2OHCOCH_2OH$ (*see* SUGARS); (5) with alkaline permanganate it gives oxalic acid; (6) with mixture of nitric and sulphuric acids it gives NITRO-GLYCERINE (*q.v.*); (7) it dissolves boric acid on heating, forming the preservative BOROGLYCERIDE. It is used in medicine and as a lubricant for watches. *See* QUINOLINE. When the hydroxyl groups in glycerine are replaced by chlorine, compounds called CHLORHYDRINS are produced; when a terminal OH group is replaced, α-MONOCHLORHYDRIN results; when the middle OH group is replaced, β-MONO-CHLORHYDRIN results; when two terminal OH groups are replaced, α-DICHLORHYDRIN results; when two adjacent groups are replaced, β-DICHLOR-HYDRIN results. They are all liquids, and are produced in the order given above by the action of hydrochloric acid on glycerine, by the action of hypochlorous acid on allyl alcohol, by the action of hydrochloric acid on glycerine, and by the action of chlorine on allyl alcohol.

Glycerol (*Chem.*) Another name for GLYCERINE (*q.v.*)

Glycin (*Photo.*) Para oxyphenylglycin, $C_6H_4OHNHCH_2COOH$. A developer somewhat resembling ferrous oxalate in being slow in its action. It develops images perfectly free from fog, even without the use of bromide. It is extremely valuable in developing a number of plates together by what is known as stand development (*q.v.*)

Glycine (*Chem.*) Another name for GLYCOCOLL (*q.v.*)

Glycocholic Acid (*Chem.*), $C_{26}H_{43}NO_6$. A colourless crystalline solid; melts at 132° to 134°; very sparingly soluble in water (less than 1 in 1,000); dextrorotatory. It occurs in the form of its sodium salt in the bile of all animals. Boiled with acids or alkalis, it yields glycocoll (*q.v.*) and cholalic acid—a substance of unknown constitution. Glycocholic acid is monobasic, and its alkali salts are easily soluble in water and in alcohol.

Glycocoll (*Chem.*), CH_2NH_2COOH (*amido- or aminoacetic acid*). A crystalline solid with sweet taste; melts with decomposition at 232° C.; soluble in water, insoluble in alcohol. It is a decomposition product of albumin, and especially of gelatine (*q.v.*) It occurs combined with salicylic acid in urine as salicyluric acid when salicylic acid has been taken; and combined with benzoic acid as hippuric acid (*q.v.*) normally in the urine of herbivora; it also occurs combined with cholic acid as glycocholic acid in bile. It is best prepared by boiling hippuric acid with hydrochloric acid; it may also be obtained synthetically by acting upon monochloracetic acid with ammonia; also by the action of hydriodic acid upon cyanogen. As it contains a basic group (NH_2) and an acid group (COOH), it forms two series of salts. Heated with baryta it yields methylamine. With ferric chloride it gives a red colour. Sarcosine and betaine are its mono- and trimethyl derivatives respectively (*see* these). *See also* DIAZO COMPOUNDS.

Glycogen (*Chem.*), $(C_6H_{10}O_5)n$. Animal starch. A white powder which forms an opalescent solution in water. It occurs in the liver of animals. It is dextrorotatory; gives a red colour with iodine. Acids convert it into glucose, and ferments convert it into maltose.

Glycollic Acid (*Chem.*), $\begin{array}{l}CH_2OH\\|\\COOH\end{array}$. A white crystalline solid; melts at 80°; very soluble in water. It occurs in the juice of unripe grapes and in turnip juice. It is prepared by boiling monochloracetic acid with water; it is also produced by oxidation of alcohol or of glycol by nitric acid, and by the action of nitrous acid upon glycocoll; it is also formed when oxalic acid is reduced by sodium amalgam. On heating it forms anhydrides. Nitric acid oxidises it to oxalic acid. It behaves like an alcohol and an acid.

Glycols (*Chem.*) Are dihydric alcohols of the paraffins. When the (OH) groups are adjacent we have the α-glycols, when separated by one carbon atom the β-glycols, and so on; *e.g.*

$\begin{array}{l}CH_2OH\\|\\CH_2OH\end{array}$	$\begin{array}{l}CH_3\\|\\CHOH\\|\\CH_2OH\end{array}$	$\begin{array}{l}CH_2OH\\|\\CH_2\\|\\CH_2OH\end{array}$
Ethylene Glycol (the simplest possible glycol).	α-Propylene Glycol.	β-Propylene Glycol (Trimethylene Glycol).

Ethylene glycol, commonly called GLYCOL, may be regarded as a type of these compounds. It is a thick sweet liquid; boils at 197°. It is obtained by boiling ethylene dibromide with potassium carbonate and water. With hydrochloric acid at 160° it forms ethylene chlorhydrin, $\begin{array}{l}CH_2Cl\\|\\CH_2OH\end{array}$; with concentrated sulphuric acid it forms the sulphate; with a mixture of sulphuric and nitric acids it forms the dinitrate. Nitric acid oxidises it to

$\begin{array}{l}CH_2OH\\|\\COOH\end{array}$	$\begin{array}{l}CHO\\|\\CHO\end{array}$	$\begin{array}{l}CHO\\|\\COOH\end{array}$	$\begin{array}{l}COOH\\|\\COOH\end{array}$
Glycollic Acid.	Glyoxal.	Glyoxylic Acid.	Oxalic Acid.

Phosphorus pentachloride gives ethylene chlorhydrin. Sodium gives first monosodium glycol, $\begin{array}{l}CH_2OH\\|\\CH_2ONa\end{array}$; then disodium glycol, $\begin{array}{l}CH_2ONa\\|\\CH_2ONa\end{array}$

Glyoxal (*Chem.*), $\begin{array}{l}CHO\\|\\CHO\end{array}$ A colourless amorphous solid which contains water: very soluble in water, alcohol, ether. It is obtained by the action of nitric acid on glycol, glycollic acid, alcohol, or aldehyde: it is best prepared from the last of these. It gives the usual reactions of an aldehyde with sodium hydrogen sulphite, with hydrocyanic acid (*see* TARTARIC ACIDS), with hydroxylamine, and with phenylhydrazine; also with ammoniacal silver. But with ammonia it yields as principal product a heterocyclic ring compound called GLYOXALINE,

$$\begin{array}{l}\quad\ \ (N)\\(\beta)CH\,.\,NH\diagdown\\ \quad\ |\qquad\qquad\ \ \rangle CH\ (\mu)\\(\alpha)CH\ .\ N\diagup\end{array}$$

(the letters are used in naming substituted glyoxalines), a white solid melting at 90° and acting as a strong base; it has many derivatives. When glyoxal is treated with an alkali, one half of the molecule is oxidised and the other half reduced, and glycollic acid results:

$$\begin{array}{l}CHO\\|\\CHO\end{array} + H_2O = \begin{array}{l}CH_2OH\\|\\COOH\end{array}$$

Glyphs (*Architect.*) Vertical channels used in the Doric frieze. *See* TRIGLYPH *and* DIGLYPH.

Glyptics (*Art*). The art of engraving or carving, especially engraving on precious stones. This art was extensively practised by the Egyptians and the Greeks.

Glyptograph (*Art*). An engraving on a precious stone.

Glyptotheca. A gallery in which works of sculpture are placed.

Gnat (*Zool.*) An insect belonging to the order *Diptera* (two-winged flies), which also includes the housefly, gadfly, and midge.

Gneiss (*Geol.*) Strictly speaking, this term is applied only to any banded aggregate consisting essentially of crystalline felspar, together with folia, leaflike bands of one or more of other rock forming minerals. In a few cases gneiss has evidently arisen through the deformation and subsequent reconstruction of an eruptive rock. In most other cases it appears to be due to the action of alkaline water at high temperature and pressure operating upon old sediments. Its minerals in some cases resemble those of granite; but there are syenite gneisses, diorite gneisses, gabbro gneisses, and other kinds.

Gnomon (*Astron.*) (1) A vertical rod used by the Greeks to observe the motion of the sun by watching the shadow. (2) The rod or plate whose shadow indicates the time on a SUN DIAL (*q.v.*)

Gobelins. The State factory of tapestry, established in Paris. The factory was founded by the family of this name in the fifteenth century, and became a royal establishment under Louis XIV. It has always been famous for the excellence of the work and the beauty of the colours employed.

Gobony (*Her.*) *See* COMPONY.

Godroon, Gadroon (*Art*). A system of ornament formed of convex curves or arcs joined at their extremities: used chiefly in the ornamentation of plate and vases, but also in architecture, costume, etc.

Going (*Joinery*). The horizontal distance between two risers (*q.v.*) in a staircase.

Going Barrel (*Watches, Clocks*). A barrel with the main wheel teeth cut upon it, driving the train direct, no fusee being used. The energy reaching the escapement is variable, being greatest when the spring is fully wound; but this has little effect on the rate of a timepiece governed by a balance and spring, and simplifies the mechanism, especially in a keyless watch. *See* TRAIN, FUSEE.

Going Part (*Textile Manufac.*) *See* BATTEN.

Gold (*Chem.*), Au. Atomic weight, 197. A yellow metal; specific gravity, 19·3; melts at 1,037° C. When pure it is absolutely unchanged in air. It is dissolved by concentrated selenic acid, forming auric selenite; also by aqua regia and by solutions of chlorine (the aqua regia acts upon it by virtue of the chlorine liberated by it), forming auric chloride, $AuCl_3$; also by dilute potassium cyanide solution in presence of air. The pure metal is extremely malleable: the thickness of gold leaf is about $\frac{1}{280000}$ of an inch. When viewed by transmitted light, gold leaf is seen to be green. When the gold leaf is made still thinner by treatment with dilute potassium cyanide solution, which dissolves gold, it transmits successively blue, violet, and red light. GOLD LEAF is made by rolling gold, then beating it out in calfskin, and finally in goldbeaters' skin (a membrane prepared from the outer sheath of the intestines of the ox). Gold is also very ductile: the gold in four sovereigns can be drawn into a wire equal in length to the earth's circumference. Gold always occurs free, but not pure; it is usually alloyed with copper, silver, tellurium, etc. Many methods are in use for extracting gold from the earthy and metallic impurities associated with it in nature: (1) Alluvial deposits are washed by a powerful stream of water into a sloping channel, the bottom of which contains crevices into which mercury is poured. The gold, being far heavier than the earthy matter washed into the channel with it, rapidly sinks and amalgamates with the mercury. (2) When the gold occurs in rock, this is broken up, then ground to powder with water. In the stamps, or grinding machine, amalgamated copper plates are placed to take up some of the gold, while the rest of the pulp is run over sloping amalgamated copper sheets, which take up more gold. The stream of powdered ore and water is run into settling tanks, when the gold which has escaped amalgamation settles, and is recovered by one of the following chemical processes: The gold amalgam from process (1), or the amalgam scraped from the copper in process (2), is distilled to free it from mercury. (3) If the gold is finely divided the material may be placed in closed vessels, and, after moistening, acted on by chlorine gas, which forms the very soluble chloride of gold. If the ore contain pyrites it must first be roasted to drive off sulphur; also the chlorine must not contain hydrochloric acid. The gold chloride is washed out of the ore by water, and the gold precipitated by ferrous sulphate solution. The black powder is melted and cast into ingots. (4) Finely divided gold is dissolved by a dilute solution of potassium cyanide in presence of air, forming a soluble double cyanide of gold and potassium, $2Au + 4KCN + H_2O + O = 2K . Au(CN)_2 + 2KOH$. The solution obtained by this process is deprived of its gold either by precipitation with zinc or by electrolysis. In the former case the gold is rubbed off from the zinc and melted and cast into ingots. A modification of process (3) consists in using chlorine gas and bromine vapour under pressure; and a modification of process (4) in using cyanogen bromide as well as potassium cyanide. When it is desired to extract a small quantity of gold from gold-containing silver (*e.g.* in assaying), the process known as PARTING BY SULPHURIC ACID is employed. The metal is granulated (*i.e.* melted and poured into cold water), and then boiled in leaden vessels with strong sulphuric acid, which converts the silver into silver sulphate and leaves the gold unchanged. During the process the sulphur dioxide which escapes is reconverted into sulphuric acid. The silver sulphate is dissolved in boiling water, the solution removed, leaving the gold behind as a black powder, which is collected when a sufficient quantity has been obtained, and melted. The silver is recovered by precipitation with copper. When gold is required quite pure, it is melted, and a current of chlorine gas is led into it, when copper, silver, arsenic, etc., are converted into chlorides, all of which volatilise except the silver chloride, and this forms a scum on the top of the melted gold, and is easily removed when the whole has solidified. The TOUCHSTONE is commonly employed in testing the purity of gold; it is a piece of black basalt or slate, on which the article to be tested is rubbed, and the streak is treated with fairly strong nitric acid containing a little hydrochloric acid. The effect produced on the streak is compared with the effect produced on streaks made by TOUCH NEEDLES containing a known proportion of gold. In this way

the proportion of gold can be estimated with fair accuracy; but if the article be coated with pure gold, a part of the surface must be ground off on the touchstone. The proportion of gold in an alloy is expressed in carats. Pure gold is 24 carat gold; the gold coinage is 22 carat (*i.e.* it contains twenty-two parts gold and two parts of copper in twenty-four parts). This coinage alloy is much harder than pure gold; it has a specific gravity of 17·2, and melts at 946°. Aluminium forms remarkable alloys with gold. An alloy containing 10 per cent. of aluminium is white, and melts about 620°; an alloy containing 22 per cent. of aluminium has a fine purple colour, and melts above the melting point of gold.

Gold (*Min.*) This element occurs native in crystals of the cubic system (usually in complex aggregations), but more often in a granular condition, in alluvial deposits, and disseminated in quartzose metamorphic rocks, where it is *in situ*. It is frequently associated with precious stones, as zircin, ruby, garnet, topaz, etc., and with certain metallic minerals, as tellurium ores, and platinum, and magnetic and titanic iron. Silver to the extent of nearly 30 per cent. may be alloyed with it, as may also copper, iron, palladium and rhodium, the latter to the extent of 40 per cent. in rhodium gold. It is of a characteristic colour, but its chief distinguishing feature is its ductility and malleability. It has been found sparingly at several places in the British Isles; it is also obtained from many places in Europe, as Konisberg, Schemnitz, Kapnite, Offenbanya, Piedmont, etc.; from the Urals, China, Thibet, India, the West Coast of Africa; largely in South Africa, Australia, India, California, Klondike, New Zealand, and Tasmania.

Gold Amalgam (*Min.*) A native amalgam of gold, silver, and mercury containing about 40 per cent. of gold. It has a whitish colour, and occurs in grains or in small crystals. It has been found in California, Central America, Australia, and Siberia.

Gold and Black Marble (*Dec.*) This marble is imitated in various ways, the simplest being to paint a solid ground in bone or ivory black, and to put in the golden yellow veins with a mixture of white, ochre, and Indian red, or raw and burnt sienna. The black spaces between the veins are then glazed with a transparent grey tint, and finally very thin white veins are put in. The marble is not difficult to imitate if a careful study is made of the veining. Sometimes leaf gold or bronze powder is used on the veins, but the practice is not one to be recommended. *See* MARBLING.

Gold Compounds (*Chem.*) AUROUS OXIDE, Au_2O, is a green powder obtained by the action of caustic potash on aurous chloride. AURIC OXIDE, Au_2O_3, forms a brown powder when dry, decomposed by light, also on heating. It dissolves in alkalis, forming AURATES, *e.g.* $KAuO_2$. It may be obtained by adding an alkali in excess to auric chloride, and reducing with sulphurous acid. With ammonia it gives fulminating gold (*q.v.*) AUROUS CHLORIDE, AuCl, is a pale yellow powder insoluble in water, obtained by heating the trichloride at its melting point. Boiled with water it yields gold and the trichloride. It is easily decomposed into its elements on heating. AURIC CHLORIDE, $AuCl_3$ (CHLORIDE OF GOLD), when volatilised, forms "large thin red crystals, very like rubies, and glorious to behold, which would run in the air, *per deliquium*" (BOYLE); melts at 288° and decomposes in air into the aurous chloride. "The decomposition . . . in air might be expected to become perceptible at 70°, requiring, however, about twenty-five years for its nearly complete change into the monochloride" (ROSE). It is very soluble in water, alcohol, and ether. Water containing organic matter reduces it. It may be prepared by dissolving gold in aqua regia; evaporating the solution, which is chloro-auric acid, $HAuCl_4$, and very gently heating to expel the hydrochloric acid. Its solution mixed with sodium thiosulphate forms sodium aurous thiosulphate, $Na_3Au(S_2O_3)_2$—a solution used in photography. Gold chloride also unites with the hydrochlorides of many organic bases, forming characteristic double salts. *See also* PURPLE OF CASSIUS.

Gold Cushion (*Binding*). A flat board on which a couple of thicknesses of flannel are laid, the whole being covered with a piece of calfskin, the rough side up. It is used to cut the gold leaf upon.

Golden Number (*Astron.*) The number of a year in the Metonic Cycle. *See* METONIC CYCLE.

Gold Leaf (*Dec.*) Is sold in a variety of qualities and colours, and, for the purposes of the gilder, is usually put up in "books," *i.e.* interleaved with paper sewn at one side, measuring 3¼ in. square, and containing twenty-five leaves of gold. In calculating the quantity of gold leaf required, it is usual to take the area as a square of 3 in., so as to allow for waste. Leaf gold is applied to a surface of gold size, when nearly dry, by means of a "tip" (*q.v.*), and adheres closely to the surface. An American system of gilding by means of long ribbons or strips of gold rolled round a small cylinder, and applied by means of a simple appliance, is growing rapidly in favour among railway carriage builders, decorators, and yacht builders.

Gold Leaf Electroscope (*Elect.*) Consists usually of two rectangular pieces of gold leaf attached to the end of a conducting rod, insulated by ebonite, glass, or, better, sulphur or paraffin wax, and screened from air currents by a glass case or shade. A charge of electricity given to the rod (either by contact or induction) causes the leaves to diverge.

Gold Paints (*Dec.*) Originally these were gold leaf ground up with some medium. They are now really bronze powders suspended in a varnish or other quick drying medium. The bronzes are alloys of copper and tin, and, owing to climatic conditions, they have to be made abroad. The brightness of the paint depends on the skill in making the bronze and the use of a medium which has no solvent action on the bronze alloy.

Goldschmidt's Process (*Chem.*) Goldschmidt, requiring some aluminium sulphide, found he could easily prepare this compound by igniting a mixture of galena (PbS) and aluminium powder. A violent reaction occurred, and he obtained lead and aluminium sulphide. Similarly from ferrous sulphide and aluminium powder he could easily obtain aluminium sulphide and metallic iron. He then examined the action of powdered aluminium on various metallic oxides, and found that on account of the enormous heat of formation of aluminium oxide, the aluminium could reduce all oxides except that of magnesium. To reduce an oxide, the latter, in the form of powder, is mixed with powdered aluminium in slight excess, and the mixture placed in a crucible. When the reduction is easy, the reaction can be started by a piece of magnesium ribbon, which is stuck into the mixture and ignited; when the reduction is more difficult, as in the case of chromium oxide, a cartridge of barium dioxide and aluminium powder is made,

and magnesium ribbon is inserted in this. It is estimated that the temperature attained in these reductions is about 3000°. The reduced metals form fused masses at the bottom of the crucible. In the case of chromium the slag contains minute rubies (Al_2O_3) coloured by chromium. Besides finding extensive use in the reduction of metals, the process has been applied to soldering iron pipes where a very high temperature is required.

Gold Size (*Dec.*) *See* JAPANNER'S GOLD SIZE, WATER GOLD SIZE, *and* MATT GOLD SIZE.

Gombron Ware (*Pot.*) A Perso-Chinese ware of a semi-porcelain character, creamy white in colour. It was so called because imported from Gombroon (Bender-Abbasi) in Persia, in the seventeenth century. An imitation of this ware was made in Chelsea.

Gonfalon. A banner suspended from a cross bar attached to a pole. The banner generally terminates in several pointed streamers.

Gonfannon (*Archæol.*) A pennon or small flag attached to a knight's lance immediately below the head.

Gong (*Clocks, Watches*). A steel wire coiled into a flat spiral form, used in clocks and repeating watches in place of a bell.

Goniometer (*Min.*) An instrument for measuring angles. There are two patterns, CONTACT and REFLECTING goniometers. In the contact goniometer two hinged metal bars are adjusted in contact with the faces whose angle of inclination is to be measured, and the angle read off on a divided circle attached. The angle is usually read as the angle between the normals of the faces, *i.e.* 180° less the dihedral angle between the faces. In the reflecting goniometer the edge between the two faces is adjusted to lie in the axis of rotation of the divided circle; the crystal is then rotated till one face reflects light from a distant signal through a reading telescope; the axle bearing the crystal is now clamped to the divided circle as it stands at zero, and the now fixed pair of wheels rotated till the signal is seen in the second face, when the angle between the faces is read off on the divided circle, again as the angle between the normals. The reflecting goniometer was introduced by Wollaston, and often bears his name.

Gooch's Link Motion (*Eng.*) *See* LINK MOTION.

Good Colour (*Print.*) A term used to imply that the result of the impression is good, the ink having been evenly and satisfactorily applied to the sheet.

Goods (*Chem. Eng.*) A general term applied to the raw oils, fats, and greases used in soapmaking; sometimes called "stock," though the latter may be bleached or partially saponified material.

Gordon's Formula (*Eng.*) An empirical formula due originally to Navier, by which the load which may be applied to a strut or column may be calculated. Let W be the load, A the area of cross section, l the length, h the thickness of the column, f the Proof Stress (*q.v.*), n a numerical constant, such that the Moment of Inertia, I (*q.v.*), of the cross section is equal to nAh^2, and c a second numerical constant, usully determined by experiment; then

$$W = A \frac{f}{1 + \frac{l^2}{cnh^2}}$$

If the column be short, so that the ratio $\frac{l}{h}$ is small, this becomes $W = Af$. If the column be long, the formula reduces to

$$W = \frac{cnh^2}{l^2} Af$$

$$= \frac{c}{l^2} I f.$$

Gorged (*Her.*) Having a collar round the neck. Many heraldic beasts are "gorged," also the supporters of the shield.

Gorget (*Armour*). A piece of armour worn in the fifteenth and sixteenth centuries, and forming a junction between the helmet and the cuirass. *See* ARMOUR.

Gorgoneion (*Art*). A representation of the Gorgon's head, one of the three mythical personages whose hair consisted of snakes and whose look turned the beholder into stone.

Goslarite (*Min.*) A hydrous sulphate of zinc, $ZnSO_4 . 7H_2O$. Oxide of zinc = 28·2, sulphuric acid = 27·9, water = 43·9 per cent. Rhombic; also massive and incrusting. White. Soluble in water. It occurs as a rarity in Cornwall and Anglesea, but chiefly in the Harz. Also from Sweden, Austria, and Hungary.

Gothic (*Typog.*) A bold faced antique type similar in appearance to black letter, used in jobbing work.

Gothic Architecture. The name applied, originally as a term of reproach, to the architecture of Western Europe from about 1150 A.D. to 1500 A.D. The principles of concentration of strain and of balancing thrusts by counterthrusts which underlie Gothic architecture led to the use of the pointed arch and the ribbed vault, two characteristic features of the style. *See* CURVILINEAR, DECORATED, EARLY ENGLISH, *and* PERPENDICULAR.

Göthite (*Min.*) Hydrated ferric oxide, $Fe_2O_3 . H_2O$. Ferric oxide = 85, water about 11 per cent., with usually some silica and manganese. Rhombic; often in flattened prisms; more often fibrous. Colours, yellow-brown to a deep blue-black. Streak (*q.v.*), a yellow brown. Often in minute crystals associated with quartz. From Cornwall, Cumberland, Prussia, United States, etc.

Go Through Machine (*Lace Manufac.*) A twist lace machine in which the principle actuating the carriages is such that they go through without any pause. Invented by Alcock of Worcester in 1835 and called the CAMEL MOTION.

Gouache (*Paint.*) A method of watercolour painting with opaque colours mixed with water, gum, and honey. A great deal of the illustrations in mediæval missals were executed in Gouache. In painting on paper the whole of the surface is covered, as in oil painting, the lights being laid in afterwards.

Gouge (*Carp., etc.*) A cutting tool similar in principle to a chisel, but having a blade whose cross section is a circular arc. PARING and SCRIBING GOUGES have the bevel on the concave side; TURNING and FIRMER GOUGES have the bevel on the outer or convex side; the latter is the more common form.

—— (*Bind.*) A brass gilding tool with a curved end, often semicircular. Gouges are made in sets, are of different diameters, and are extremely useful in working out designs on book sides.

Gouge (*Forge*). A hollowed tool used in smiths' work; usually held by a handle and struck by a sledge hammer.

Gouge Bit (*Carp.*) A boring tool or bit in the shape of a gouge, without any central point or cutting lip.

Gouge Slip (*Carp., etc.*) A thin piece of oilstone, etc., with a rounded edge; used in setting and sharpening gouges.

Gouttes (*Her.*) *See* GUTTÉE.

Governing Motion (*Cotton Manufac.*) An attachment to the mule for regulating the tension of the threads as they are wound on during the formation of the copbottoms. Sometimes termed the STRAPPING MOTION.

Governor (*Gasfitting*). An apparatus for regulating the pressure of gas. *See* GAS REGULATOR.

Governors (*Eng.*) A governor is an automatic mechanical device for controlling the speed of a steam engine, gas engine, or other prime mover; it serves, to some extent, the same purpose as the pendulum of a clock. In the original form, due to Watt, it consisted essentially of a spindle A (fig. 1), which is caused to rotate by the engine at a speed which varies with the speed of the crank shaft. Two heavy balls B, B are hinged to A by two arms C, C, which are connected by links D, D to a collar or sleeve E which can move up and down the spindle A. This sleeve is connected by a system of levers F, G, to the THROTTLE VALVE (*q.v.*) of the engine, so that E opens the valve as it falls, and closes it again as it rises. An increase in the speed of the engine causes the balls to fly outward and raise the sleeve E, which acts on the throttle valve and partially cuts off the supply of steam until the speed falls to its normal value; if the speed fall below the normal value, the throttle valve is opened more widely, and the engine gains speed. There are many modifications of this simple form of governor.

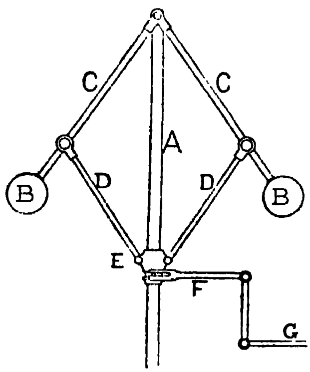


FIG. 1.

A LOADED GOVERNOR (fig. 2) has a heavy mass M attached to the sleeve E; it is suitable for higher speeds than the simple form. A CROSSED ARM GOVERNOR (fig. 3) has the arms hinged to a cross-piece at the top of the spindle A, so that the joints of the arms and the balls are on opposite sides of the spindle A. If the centres on which the two arms turn be properly chosen, the governor is practially ISOCHRONOUS; that is the governor remains very steady at one fixed speed, but a very slight alteration will cause the balls to fly to their highest or lowest point, according as the speed has increased or diminished. A strictly isochronous governor would be too sensitive for convenience, as it would cause HUNTING or over-correction of the speed: *i.e.* when the governor was acting so as to increase the speed, it would increase it too much; this would lead to a sudden change in the opposite sense, and so on. In certain cases a governor is fixed on the main shaft, with loaded arms moving in a vertical plane. One such form is shown in fig. 4. The main shaft A carries a circular case or frame B; two heavy masses C, C are fixed to the frame by pivots at D, D, and are kept in a position of equilibrium by springs E, E. An increase of speed causes the arms to fly outwards, and their motion is communicated by links F, F to a lever G. The motion of G is communicated to the throttle valve (or other controlling device) by means of a system of levers or other mechanism. A gas engine generally has a governor of the ordinary type; but instead of acting on a throttle valve, it usually causes the engine to miss one or more explosions when the speed rises above a certain limit. Various types of governor have also been invented which control the character of the mixture, *i.e.* which alter the relative proportions of air and inflammable gas in the charge; but the simpler arrangement is found to be more satisfactory.

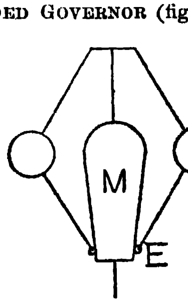

FIG. 2.

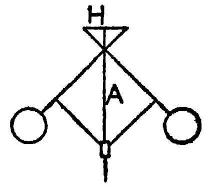

FIG. 3.

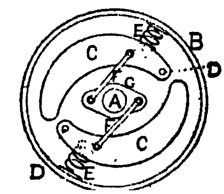

FIG. 4.

Grab (*Eng.*) A mechanical excavator or steam navvy, the essential part consisting of a steel bucket opening in two halves like jaws, the bucket being lowered and raised by levers or chains actuated by a form of crane. The jaws are opened automatically as the bucket is lowered; when the latter strikes the surface of earth, sand, mud, or other loose material, it sinks in for a certain distance. The jaws are then forced together mechanically, and the bucket with the enclosed material raised.

Grace Cup. A loving cup. The custom of handing round a large cup filled with wine after grace has been said came into vogue early in the Middle Ages.

Gradient (*Civil Eng.*) The slope of a road or railway. The RULING GRADIENT is the greatest slope allowed on any particular line; it varies with circumstances. In railways in mountainous districts it may reach 1 in 25, which is generally regarded as the limit for locomotives with smooth wheels, depending on the adhesion between the wheels and the rails. Higher gradients require the use of a toothed rack or some equivalent device. *See* FELL RAILWAY *and* MOUNTAIN RAILWAYS.

——, **Barometric** (*Met.*) The steepness of the slope of isobaric surfaces. This steepness is measured by the difference in barometric pressure along the same level. *See* ISOBAR.

Gradine (*Architect.*) A step or low steplike seat forming one of a series, *e.g.* the seat in an amphitheatre; also a shelf at the back of an altar.

—— (*Sculp.*) A toothed chisel.

Grading (*Cotton Manufac.*) A system of classifying cotton to determine its quality and value. A rough classification is as follows:

American.	*Brazilian.*	*Egyptian.*	*Indian.*
Good ordinary.	Mid. Fair.	Fair.	Fair.
Low Middling.	Fair.	Good Fair.	Good Fair.
Middling.	Good Fair	Good.	Good.
Good Middling.			Fine.
Mid. Fair.			

The first mentioned are the lowest qualities in each case.

Gradometer (*Surveying*). An instrument for measuring the angle of dip of a rock formation or mineral deposit.

Graduation Towers (*Chem. Eng.*) Stacks of brushwood used for the natural evaporation of brine in the manufacture of salt. Used in Continental practice only.

Graffito, *pl.* **Graffiti** (*Archæol.*) A drawing or writing scratched on a wall or other surface; notable examples are to be found in Egyptian tombs, Pompeii, Rome, etc. *See also* SGRAFFITO.

Graham's Law (*Chem.*) Gases diffuse at a rate which varies inversely as the square roots of their densities. *See* DIFFUSION.

Graham's Mecurial Pendulum. *See* PENDULUMS.

Grain. *See* WEIGHTS AND MEASURES.

Grain. The fibrous structure of wood or of certain metals, or various other substances. The expression "with the grain" means along the direction of the fibres; "across the grain" or "cross grain" means a direction more or less at right angles to them.

Graining (*Chem. Eng.*) *See* CUTTING.

—— (*Dec.*) The art of imitating by means of oil or water paint the grain of wood. *See also* MARBLING. Formerly graining was used to a considerable extent in finishing the woodwork of dwelling houses and other buildings, but of late years it has almost ceased to be used excepting in country districts, coloured paint work having largely taken its place. Graining possesses the advantage of being the most durable class of paint work, and when covered with a good varnish it is very suitable for kitchens, passages, and other places subjected to great wear. Although graining has been condemned by Ruskin and other writers as a sham, its convenience and durability render it likely to remain in use for many years. The tendency at the present time is toward an increase in the use of graining. If properly executed in appropriate positions, it does not offend artistic taste. Sometimes, however, the grainer places his work in situations altogether inappropriate; for example, on a solid cast iron or steel column supporting a beam. In such a case, if the column is grained to represent wood the effect is bad, because if the column were actually made of wood it would obviously break under the strain imposed upon it. In steamboats and other vessels graining is also used without due thought, as, for instance, on metal linings. The safe rule to follow is that graining can be employed in any situation where the surface grained might actually be constructed of the wood that is imitated. In all cases the surface of the work it is intended to grain should be prepared precisely in the same way as for ordinary painting, four coats being generally given on new work. The final coat should be the lightest colour of the wood to be imitated. The surface must be quite solid and level, free from any absorbent quality. The grounds should be rich and warm in tone, but not too bright or glaring. A little less oil than usual may be used in the last coat. The principal GRAINING GROUNDS are prepared as follows: *Ash:* This ground is best made of white lead tinted with a very little vermilion and sufficient lemon chrome. Yellow ochre may be used lightened with lead. *Antique Oak:* White lead tinted with French ochre, burnt umber, and Ventian red gives a good antique oak ground which must be kept quite dark. *American Walnut:* White lead tinted with French ochre, burnt umber, and Venetian red gives this ground, which is practically the same as the ground intended for antique oak, but many grainers prefer to add burnt sienna. *Birch:* White lead, to which has been added a little yellow ochre, produces a good birch ground. White lead, French ochre, and a little yellow chrome are sometimes preferred. *Dark Oak:* White lead mixed with a little golden ochre gives a good ground, and a little Venetian red and burnt umber may be added if desired. *Light Oak:* White lead and yellow ochre, to which has been added a little lemon chrome, if desired. *Maple:* White lead should be tinted with vermilion and a little lemon chrome. *Medium Oak:* French ochre and white lead with a little burnt umber give this ground. *Mahogany:* Venetian red, orange, chrome yellow, and burnt umber give a dark mahogany ground which may be lightened if desired by the addition of white lead. *Pitch Pine:* Venetian red and white lead with a little French ochre. *Satinwood:* Lemon chrome and white lead with a very little English vermilion give this ground. *Knotted Oak:* White lead, French ochre, and burnt umber. *Rosewood:* Same as dark mahogany. Upon the surface, when thoroughly dry, the graining colour is painted. This colour varies in composition with the wood to be imitated. It is usually somewhat thin and transparent, and is applied with a brush in streaks. The graining colour is partly removed by means of steel combs with teeth of varying width, and also by means of a cloth held over a thumbpiece of horn, shaped for the purpose. The following GRAINING COLOURS are chiefly used. *Ash:* Same as light oak *American Walnut:* Burnt umber and a little Vandyke brown. *Birdseye Maple:* Raw umber and raw sienna toned down with a little Vandyke brown or ivory black. *Cherry:* Raw sienna and burnt sienna and raw umber. *Chestnut:* Raw sienna, Vandyke brown, and raw umber, to which may be added a little burnt sienna. *Mahogany:* Burnt umber, burnt sienna, and Vandyke brown. *Rosewood:* Vandyke brown, with the addition of a little black. *Light Oak:* Burnt umber and raw sienna, to which is added a very little black. The ground having been painted over with the graining colour, the grainer proceeds as follows: In the case of oak he draws the comb along those portions of the work, such as the stiles and rails in a door, which are likely to be a straight grain, thus imitating it very quickly and in a simple manner. The panels, however, are supposed to be cut out of a different part of the log of wood, and in this case it is necessary to put in the light marks known as "champs." When the whole of the work has been imitated by removing part of the colour, it is usually "overgrained" with colour ground in water; a little blue black is frequently used. This is laid on with a hoghair brush, known as an "overgrainer," and softened with a badger hairbrush, so as to produce the difference of light and shade in the various

parts. Stale beer, gum, glycerine, or Fuller's earth are added to bind the overgraining colour. Mahogany is grained by wiping off larger portions of the graining colour and softening one part into the other. The various processes of graining the different woods are too lengthy and of too technical a description to be described here. In some cases a roller is finally passed over the work. These rollers consist of a number of discs with notched edges, which revolve against a brush charged with a dark water colour, the result being a number of irregular dotted lines over the face of the work. Various mechanical methods are also used for graining. The most commonly used is what is known as transfer graining paper. This consists of paper having on it the grain of the wood printed in distemper colour, which can be transferred on the paper being dampened. There is a stiffness in appearance in this class of work which stands in the way of its being used very extensively; but if care is taken to blend the pattern before it is dry, a very creditable job may be made of it. Another mechanical method consists of graining with a material known as "Gransorbian," which is like thick blotting paper. This is pressed against the wet graining colour, thus producing an appearance like the grain of wood. Rollers having the grain in relief are also used for cheap work, but the repetition of the pattern stands in the way of their being used for anything except the very commonest work. The test of all graining is how near it approaches to the actual wood in appearance. Students in graining usually copy from choice specimens of wood, so as to get the appearance produced by nature.—A. S. J.

Graining (*Leather Manufac.*) A fictitious grain may be imparted to a skin by passing it through the rollers on which the grain markings are engraved. A sheepskin is frequently printed with a goat grain or even with alligator, crocodile, or pigskin grain. *See also* BOARDING.

Graining Boards (*Binding*). Beech or pear tree boards cut in *intaglio* with different designs, and used to impress patterns on the sides of whole bound calf books by pressure.

Grain Leather. Leather dressed with the grain side outwards.

Grain Side (*Leather Manufac.*) The side of the skin on which the hair grew.

Grains of Paradise. The pungent aromatic seeds of *Amomum melegueta* (order, *Zingiberaceæ*), known also as GUINEA GRAINS, have been used as an adulterant of beer and spirits.

Grain Split (*Leather Manufac.*) *See* BAG HIDES.

Grain Tin (*Met.*) Tin of the purest quality, produced by heating refined tin to a temperature rather below the melting point. At this temperature it is very brittle, and is broken up either by a hammer or by being dropped from a height.

Gram. *See* WEIGHTS AND MEASURES.

Gramineæ (*Botany*). The grasses form a large order of *Monocotyledons*; they vary in habit and structure from the annual herbaceous grasses to the giant bamboos. Their economic importance is well known.

Gramme Armature (*Elect. Eng.*) The early form of RING ARMATURE. *See* ARMATURES.

Gram Molecule (*Chem.*) The molecular weight of a substance taken in grams, *e.g.* a solution containing a gram molecule of cane sugar is one containing 342 (the molecular weight of cane sugar) grams of cane sugar.

Granite (*Geol.*) A name for a group of rocks which have slowly consolidated from a fluid state under enormous pressure, and which consist essentially of a granular holocrystalline aggregate of alkali-felspars and quartz, with or without accessory minerals of other kinds. The constituents normally occur in such a manner as to show that each mineral in consolidating has grown so as to hinder its neighbours from assuming the crystalline boundaries proper to the species; in other words, the structure is granitic, and the constituents are allotriomorphic with respect to each other.

Granite Weaves (*Woollen Manufac.*) Small weaves or schemes of interlacing warp and weft, giving indefinite patterns.

Granitic Structure (*Geol.*) This is due to the conditions of pressure and temperature which prevailed when the rock exhibiting it was undergoing consolidation. Each separate mineral constituent has grown in such a manner as to prevent the crystals adjoining it from assuming their own proper bounding planes. Minerals which behave thus are said to be allotriomorphic with respect to each other. In granitic structures, therefore, the mass is holocrystalline, and the mineral constituents are allotriomorphic. The structure characterises granite, syenite, diorite, gabbro, and some few other rocks of eruptive and deep seated origin.

Granolith, Stuart's. *See* ARTIFICIAL STONE.

Granophyre (*Geol.*) A name formerly used for certain types of granite in which some of the quartz and felspar show the curious intergrowth which characterises GRAPHIC GRANITE. These granophyric granites appear to have been formed at lesser depths than granite of the normal kind. In some cases they appear as if they had originated through the solution of an older basic rock by the action of a magma containing much potash and silica, and the subsequent recrystallisation of the compound deep within the core of a full grown volcano.

Grant Reel (*Silk Manufac.*) A particular form of reel which enables the skein to be wound more fully and economically. To form the skein, the thread passes on to a reel, as in ordinary reeling; but owing to the traverse motion being regulated by a particular multiple of wheels the traverse is laid on in diamond form, thus creating spaces which are afterwards intersected with lacing thread to retain the cross or traverse.

Granular Iron (*Met.*) Iron whose fractured surface shows a regular granular structure. This denotes a good quality of metal.

Grape Seed Oil. Made from the seeds of grapes removed from the fruit during the preparatory process of brandy making. The seeds are ground, and when expressed yield a thick yellow oil, which may be used for cooking purposes, as a substitute for olive oil, and in soap and varnish making. The supply, however, is very limited.

Grape Sugar (*Chem.*) Another name for DEXTROSE (*q.v.*)

Graph. A curve showing the relation between two variables, *e.g.* a curve showing the height of the

barometer throughout the day. Graphs are "plotted" or drawn either from two sets of observations or from an equation which expresses the relation between the two variable quantities.

Graphic Calculation (*Mech.*, *Phys.*, *etc.*) The calculation of numerical results based upon the representation of quantities by lines. The most important example is furnished by GRAPHIC STATICS (*q.v.*)

Graphic Formulæ (*Chem.*) *See* CHEMICAL FORMULÆ.

Graphic Granite (*Geol.*) A granite (*q.v.*) in which the quartz and the felspar have simultaneously intergrown with each other. The component minerals form, in consequence, a series of markings, bearing a fancied resemblance to written characters.

Graphic Statics. The calculation of the forces acting on structures (roofs, bridges, etc.) can be carried out very much more easily by graphic methods (*i.e.* by drawings made to scale) than by abstract calculations. The graphic method is based chiefly on the theorem known as the POLYGON OF FORCES, which may be stated as follows: If any number of forces act at a point in a body which remains at rest under their action (that is, if the forces are in equilibrium), then the forces can be represented in magnitude and direction by the sides of a polygon taken in order. Thus if the lines 1, 2, 3, 4, 5 (fig. 1) represent forces acting at a given point, then these forces may be represented by the lines 1, 2, 3, 4, 5 in fig. 2, each line being parallel to the direction of the force which it represents, and of length proportional to that force. Fig. 1 is often termed the FORCE DIAGRAM; fig. 2 is the POLYGON OF FORCES which

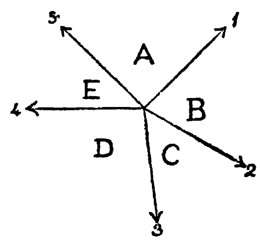

FIG. 1.

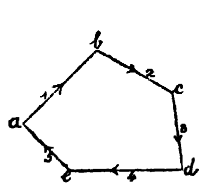

FIG. 2.

corresponds to it. The most convenient way of naming these forces is by means of BOW'S NOTATION. Letters A, B, C, D, E are placed as shown, and the force 1, which acts along the line separating the space A from the space B, is termed the force AB. In the polygon (fig. 2) the line parallel to AB is marked *ab*, the letters being placed at the ends of the line. Fig. 2 is a figure whose sides are respec-

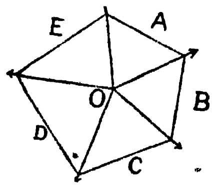

FIG. 3.

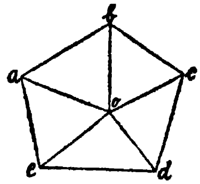

FIG. 4.

tively parallel to the lines in the first figure, and is said to be the RECIPROCAL FIGURE to fig. 1. If any point *o* be taken, and lines *oa*, *ob*, *oc*, *od*, *oe* (fig. 4) be drawn to the angles of a polygon of forces, the figure so formed is termed a POLAR DIAGRAM, and the point *o* is termed its POLE. If now a reciprocal figure to the polar diagram be drawn in conjunction with the original diagram showing the direction of the forces, or FORCE DIAGRAM (fig. 1), in such a way that a line parallel to *oa* is drawn across the space A (in any convenient position), a second line, starting from the end of this, across the space B and parallel to *ob*, and so on, we get the figure called the FUNICULAR POLYGON (fig. 3). For any system of forces in equilibrium, the funicular polygon is a closed figure, whatever be the position of the POLE *o*. This statement is true whether the forces act at a point or not. If we are given a system of forces which are not in equilibrium, we can find the magnitude, direction, and position of the force necessary to keep the system in equilibrium. The Polygon of Forces will give us the magnitude and direction of this force or Equilibrant; the Funicular Polygon will give a point on its line of action, from which we can find its point of application. The force is therefore completely determined. The following example indicates the method of finding this force or EQUILIBRANT for a system of parallel forces, such as those of a loaded beam. Let the forces act along parallel lines represented in Bow's Notation by AB, BC, CD, DE (fig. 5), and in magnitude and direction by *ab*, *bc*, *cd*, *de* (fig. 6), each of these lines being proportional to the magnitude of the force which it represents. Draw the Polar Diagram from any pole *o* (fig. 6), and in the spaces B, C, D draw lines parallel to *ob*, *oc*, *od*. Now let lines in the spaces A and D be drawn parallel to *oa* and *od*, and produced till they meet. The point where they meet will be

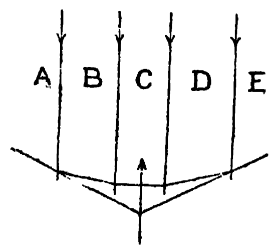

FIG. 5.

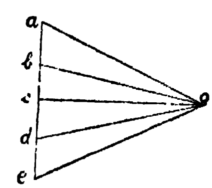

FIG. 6.

the point where an upward force, equal in magnitude to *ae* (the sum of the loads AB, BC, etc.), and in a direction parallel to *ac* (and therefore to AB, BC, etc.), must be applied, in order to balance the downward forces. In such a case as this, where the forces are parallel and in the same direction, the figure *abcde*, or Polygon of Forces, becomes a straight line; it is then usually termed the LINE OF LOADS.

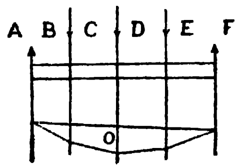

FIG. 7.

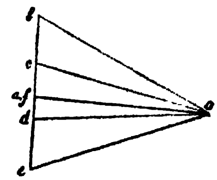

FIG. 8.

The Funicular Polygon is also applied in finding the forces required to be applied to support a loaded beam, that is the REACTIONS AT THE SUPPORTS,

Let BC, CD, DE (fig. 7) be the loads, acting downwards, and let AB and EF be the position of the reactions. Draw the line of loads *bcde* (fig. 8) and the polar diagram from the pole *o*. Construct the Funicular Polygon by lines in the spaces B, C, D, and E parallel respectively to *ob*, *oc*, *od*, and *oe*. Draw the closing line of the Funicular Polygon, as shown by the heavy line, and from *o* draw a line *oa* parallel to this closing line, cutting the line of loads in the point *a*. Then *ba* represents the reaction at AB, and *ea* (or, as it may be marked, *ef*) the reaction at EF. The above is one of the most simple cases; but graphic methods are applicable to very complicated cases of framed structures, such as iron bridges, built up girders, roofs, cranes, etc. Wind pressure in roofs, oblique reactions at the supports, the effect of ceiling loads, and numerous other effects can readily be calculated by methods based entirely on the fundamental principles enunciated above.

Graphic Tellurium (*Min.*) A telluride of gold and silver, $(Au.Ag)Te_2$. The gold and silver equal about 40 per cent. together. It occurs grey or silver white crystals with a high metallic lustre, arranged in lines so as to give some resemblance to writing; hence the name. Also called SYLVANITE. From Transylvania and California. It is a very valuable ore of gold when in sufficient quantity.

Graphite. Carbon: hexagonal. Also called Plumbago and Blacklead. Occurs usually in foliated masses, sometimes in hexagonal plates, in metamorphic rocks chiefly. It is one of the few minerals which leave a shining black streak when rubbed on paper. From Cumberland, India, Ceylon, Bohemia, etc. It is used to make pencils, to form a conducting coating of moulds in electrotyping, etc.; as a lubricant (*e.g.* for wood surfaces and cycle chains), and as blacking (*q.v.*) for moulds in the foundry.

Graphitic Carbon (*Met.*) The carbon which is mechanically diffused in pig iron, as opposed to combined carbon. It gives the characteristic crystalline fracture to grey pig iron. *See* KISH.

Grass (*Mining*). The surface of the ground above the mine. BROUGHT TO GRASS means raised to the surface.

Grassing (*Linen Manufac.*) After retting (*q.v.*) the flax straw is spread over grass fields to get the sun and air and complete the retting process, and during the process of bleaching also the yarn or cloth is spread on grass fields. This assists to whiten it, and avoids the necessity of using strong chemicals. This spreading is called "grassing."

Grass Wrack (*Botany*). A submerged marine flowering plant, *Zostera marina* (order, *Naiadaceæ*) common on the shores of Britain. The dried plant is much used for packing glass and for stuffing cushions and mattresses.

Grate (*Eng., etc.*) The portion of a furnace or firebox which supports the fuel during combustion.

Grate Area (*Eng.*) The surface required to burn enough coal to produce the power at which the boiler is to be worked: it is usual to quote the amount of surface needed to consume 1 lb. of coal, the number of pounds of coal being determined by the horse power required.

Grating (*Phys.*) A surface ruled with very fine lines (5,000 to 40,000 per inch), used to produce DIFFRACTION SPECTRA (*q.v.*) The ruling may be on a glass plate (TRANSMISSION GRATING) or on a reflecting surface (REFLECTION GRATING). *See* DIFFRACTION GRATING.

Grating (*Build.*) The perforated cover of a gully, etc.

Grave (*Music.*) Slow: heavily.

Grave Accent (*Typog.*) A sign placed over a letter thus, è.

Gravel (*Geol.*) A term usually restricted to any loose accumulation of subangular stones which have been worn and sorted by the action of running water, especially by that of a river. Similar accumulations which have been more completely rounded are often distinguished as SHINGLE. In the south of England the term is usually understood to mean "flint gravel," in which the stones are more angular than is usual.

Graver. A tool used in hand turning, consisting of a steel blade of square section, with the end ground off diagonally so as to produce a rhombus, the outer edges of which constitute the cutting edges of the tool: the pointed end is also utilised.

—— (*Engrav.*) *See* BURIN.

Graving Dock (*Civil Eng.*) A small dock (usually large enough to contain one vessel) which can be emptied of water to enable repairs to the ship's bottom to be carried out. The dock is of such depth that on admitting water at high tide a vessel can be floated in or out with ease.

Gravitational Astronomy. The dynamical theory of the heavenly bodies, dealing with their attraction on one another, their masses, etc.

Gravitation, Gravity (*Phys.*) The force with which one mass attracts another; in particular the force of attraction exerted by the Earth on a body, or the force exerted by one planet or other celestial body on another. The actual attraction between two bodies on the Earth's surface is very minute and can only be detected by special apparatus of great delicacy. The mathematical expression for the force f between two particles of mass m_1 and m_2, separated by a distance d, is $f = \frac{\quad}{d^2}$ The constant k is termed the CONSTANT OF GRAVITATION: its value is about $6{\cdot}6576 \times 10^{-8}$ in centimetre gram second units. Thus two small particles, each having a mass of 1 gram, placed 1 centimetre apart, would attract each other with a force of $6{\cdot}6576 \times 10^{-8}$ dynes. From the same constant it is possible to calculate the total mass of the Earth, and thence its density, which is found to be 5·527 times that of water.

Gravity, Centre of. *See* CENTRE OF GRAVITY.

Gravity Escapement (*Clocks*). A clock escapement in which the vibrations of the pendulum are sustained by the fall of the gravity arm through a constant height. *See* ESCAPEMENT.

Grazioso (*Music*). *See* CON GRAZIA.

Grease. The rendered or melted fat of animals; oily matter, especially as used in various manufactures and as a lubricant. *See* CANDLES *and* SOAP.

Grease Box (*Eng.*) A hollow box immediately above the axle bearing of a locomotive or truck, containing grease for lubricating the bearing.

Grease Traps (*Hygiene*). It is necessary in the case of hotels, clubs, etc., that special means be adopted for receiving the discharges from the scullery sink waste pipes. The ordinary gully traps are not suitable for this purpose, as the fatty matter solidifies on entering, and causes obstruction in the drains. The evil can be corrected either by fixing a trap which collects the grease and from which it can be removed by hand, or by adopting an appliance

where the solidified grease can be broken up before entering the drain. The latter method is preferable. In an efficient grease trap there should be (1) a good body of water: this rapidly cools the grease, causing solidification; and (2) a discharge from an automatic flush tank should be connected with the trap, by means of which the congealed mass is broken up and can then pass into the drains.

Great Circle (*Astron.*) The line on the surface of a sphere formed by the intersection of a plane passing through the centre of the sphere.

Great Millet (*Botany*). *See* DHURRA.

Great Organ (*Music*). That part of the organ having the heaviest stops. In two-manual instruments the great keyboard is the lower, and in three, four, or five manuals it is the lowest but one.

Great Primer (*Typog.*) Type one size smaller than Paragon. *See* TYPE.

Great Wheel (*Watches, Clocks*). The first or main wheel of a watch or clock. Usually the largest wheel in the train and the nearest to the weight or spring. It is the first of the series of agents transmitting energy from the weight or spring to the escapement. *See* TRAIN.

Greaves (*Armour*). Armour forming a covering for the legs below the knee. Greaves were worn by ancient nations as well as in the Middle Ages. *Cf.* JAMBART *under* ARMOUR.

Greaves *or* **Graves.** Animal tissue left after melting off fat at a high temperature. The greaves are usually pressed for a further supply of fat, and finally formed into cakes as food for dogs, swine, etc.

Greek Architecture. The trabeated style of architecture which obtained in Greece, Sicily, and Asia Minor. The principal buildings of note were erected during a period commencing about 650 B.C. and ending about 100 B.C.; the great masterpieces of Greek art were constructed between the years 460 B.C. and 400 B.C. The latter period is known as the Periclean age, as it was during the administration of Pericles that Ictimas and Callicrates designed the Parthenon, the sculpture of which was executed by Phidias. *See* ARCHITECTURE, ORDERS OF, *and* ROMAN ARCHITECTURE.

Green. *See* COLOURS (PIGMENTS, DECORATIONS, *etc.*) *and* BRUNSWICK GREEN, CHROME GREEN, EMERALD GREEN, MINERAL GREEN, *etc.*

Green Bricks. *See* BRICKS.

Green Carbonate of Copper (*Min.*) A synonym for MALACHITE (*q.v.*)

Green Fog (*Photo.*) This is a dichroic fog, being green by reflected light and red or pink by transmitted light. It is very frequently seen on negatives taken on orthochromatic plates, more especially when ammonia has been used in the developer.

Greenheart. *See* WOODS.

Green Liquor (*Chem.*) The liquor left from the bleaching of palm oil by the bichromate process. It is sometimes treated to recover the chromium it contains.

Greenockite (*Min.*) Cadmium sulphide, CdS. Cadmium = 77·7, sulphur = 22·3 per cent. In hexagonal yellow crystals, with the two terminations different (hemimorphic). Also rarely as an incrustation on zinc blendes; *e.g.* from Wanlockhead in Dumfriesshire. Chiefly from the Bishopstown tunnel in Dumbartonshire; also from Bohemia, Greece, and Pennsylvania.

Green Oil (*Chem. Eng.*) (1) The second fraction which comes over in the distillation of Yorkshire grease. Occasionally used for coarse lubricating greases, but usually reworked with another batch of grease. (2) A product in GAS MANUFACTURE (*q.v.*)

Greensand (*Geol.*) In the geological sense GREENSAND is usually understood to mean the rocks which lie between the Chalk and the Gault (the UPPER GREENSAND) and those which lie between the Gault and the Wealden Beds (the LOWER GREENSAND). In both cases the name was given because the presence of grains of Glauconite imparts a greenish colour to the sands of these formations. Both are important sources of water supply in the south east of England.

Green Sand (*Moulding*). Moist foundry sand, as distinguished from sand which has been mixed with clay, etc., to form loam (*q.v.*), or from sand which has been dried.

Green Vitriol (*Chem.*) A common name for ordinary crystallised ferrous sulphate, $FeSO_4 7H_2O$. *See* IRON COMPOUNDS.

—— (*Min.*) A synonym for MELANTERITE or COPPERAS (*q.v.*)

Green Wood. Timber still containing some of its original sap, which must be removed by seasoning before the timber is fit for use.

Gregorian Calendar (*Astron.*) The calendar as adopted by employing the corrections ordered by Pope Gregory in 1582.

Gregorian Modes (*Music*). *See* MODES.

Gregorian Telescope (*Astron.*) A form of reflecting telescope in which the observer views the object by looking through an aperture in the primary mirror at the image formed by a small concave reflector in the primary axis.

Grenadine (*Textile Manufacture*). An open texture in stripes or checks, several threads being compacted together in the warp, in the weft, or in both, and open spaces intervening.

Grey (*Paint.*) A colour intermediate between black and white. A mixture of black and white.

—— (*Textile Manufac.*) A term used to describe yarn or "slubbing" as it comes from the loom before undergoing any process of bleaching or dyeing.

Grey Copper (*Min.*) A synonym for TETRAHEDRITE (*q.v.*)

Grey Lime (*Build.*) A lime prepared from grey chalk.

Grey Pig (*Met.*) Pig iron which gives a flaky crystalline fracture which is dark grey, due to graphitic carbon (*q.v.*) For foundry use it is a hard iron giving a fluid metal in the ladle. White pig is a definite carbide of iron, the carbon being combined. Is more sluggish than grey, and usually contains more sulphur. Mottled pig is intermediate between grey and white pig. *See also* IRON.

Grey Sour (*Cotton*). Dilute hydrochloric (muriatic) acid, used to decompose the lime soaps formed in the lime-boiling kier in cotton bleaching.

Greywacké (*Geol.*) An Anglicised form of the German name Grauwacké, which is now applied by British geologists to an impure form of quartzite which constitutes a large part of the Silurian, Ordovician, Cambrian and pre-Cambrian rocks of marine

sedimentary origin. The Coniston Grits of the English Lake District consist almost entirely of typical greywacké.

Grid (*Eng.*) A general term for structures composed of parallel bars, *e.g.* a grating over the opening of a pipe, etc.

Griddle (*Mining*). A sieve or grating.

Gridiron Pendulum. *See* PENDULUMS.

Gridiron Valve. A slide valve containing parallel rectangular openings or ports; the solid portions between the ports cover corresponding openings or ports in the valve seat, so that a small movement of the valve will uncover a large port area by bringing the two sets of openings opposite each other.

Griffe (*Architect*). A projecting spur at the base of a column; found chiefly in mediæval architecture.

—— (*Textile Manufac.*) The frame containing the lifting bars in the harness or Jacquard loom.

Griffin *or* **Gryfin,** *anciently* **Gryphon** (*Her.*) A fabulous beast with eagle's head and claws joined to a lion's body. When borne as a charge it is generally "passant," but when erect and wings expanded it is called "segreant." Griffins are frequently borne as supporters.

Griffith's White (*Dec., etc.*) A white pigment similar in composition to Orr's Zinc White (*q.v.*)

Grille (*Build., etc.*) (1) A grating. (2) A screen made in the form of a grating.

Grinder (*Paper Manufac.*) A machine used for making mechanical wood pulp (*q.v.*)

Grinding. (1) The process of crushing a material into powder or small particles. (2) The removal of material from an object by the action of some abrading substance; *e.g.* an emery wheel, grindstone, etc.

—— (*Textile Manufac.*) An operation performed periodically by means of emery rollers on the wire edged surfaces of the cylinder, doffers, flats, etc., of a carding engine, so as to ensure accurate carding. The particular method of grinding is determined in a large measure by the staple to be carded. There are several forms of grinding, such as PLOUGH GRINDING, TOP GRINDING, SIDE GRINDING, etc.

Grinding In (*Eng., etc.*) Fitting a plug or valve to its seat by placing a little fine emery on the valve and rotating it in its seat until a good fit is secured. The valves of gas engines, petrol motors, etc., require to be ground in at intervals when they become loose through corrosion caused by the hot gases in the cylinder.

Grinding Rest (*Eng., Carp., etc.*) A device used to support a tool which is being ground, so that the edge is sharpened to the correct angle.

Grinding Stone (*Eng., etc.*) (1) A flat stone used for grinding pigments. (2) A circular stone mounted on a frame, and used for grinding tools; usually termed a GRINDSTONE.

Grindstone. A circular rotating disc of some natural sandstone (*e.g.* the carboniferous sandstone from Newcastle), more rarely made of some artificial composition; generally used for sharpening cutting tools and implements.

Grisaille (*Paint.*) A method of painting in monotone, grey tints only being employed. Generally used for representing solid bodies in relief, *e.g.* friezes, bas-reliefs.

Grits (*Geol.*) A term applied somewhat loosely to any rough textured sandstones. It is very generally used for the pebbly sandstones of the Carboniferous Rocks, and especially for those whose texture fits them for use as millstones.

Grizzle (*Build.*) A stock brick, underburnt, but of good shape.

Groin (*Architect*). *See* GROINED VAULT.

Groined Vault (*Architect.*) A groined vault is formed by the intersection of two barrel vaults, the angles formed at the intersection being known as GROINS. The groins divide the vault over a rectangular space into four parts, hence the terms quadripartite and four-part vault. A groined vault must be constructed as one structure, wooden centring being used to support the whole. This form of vault was used by the Romans and also in the Romanesque style. *See* BARREL VAULT, VAULT, *and* RIB AND PANEL VAULT.

Grolier (*Binding*). A style of book ornamentation introduced into France in the time of Henri Deux by his Chancellor, Grolier, who is supposed to have learned it in Italy. It consists of interlaced strap work of different colours, applied to book sides. It bears great similarity to some kinds of early Celtic decoration.

Grooving. (1) A general term for cutting a groove. (2) The production of the groove in the edge of a board which is to be joined to another board provided with a TONGUE or strip fitting the groove; it is done either by hand with the PLOUGH (*q.v.*) or by a revolving saw or cutter of suitable thickness.

Grooving (*Eng.*) The tendency of corrosion in steam boilers to develop cracks into grooves. It occurs chiefly along the edges of laps, angle bars, and doubling plates, owing to the shell being too stiff to allow the boiler to "breathe," *i.e.* expand and contract evenly. Cylindrical shells, if too firmly seated, suffer from grooving, owing to the plates buckling near lap and butt straps, especially at ring seams. But in vertical fireboxes want of stiffness causes grooving through the mud ring not being deep enough. Grooves often owe their origin to the use of caulking tools which are square or sharp, instead of being perfectly round nosed.

Grooving Saw (*Carp., etc.*) A revolving saw used for cutting a groove in timber for a tongue and grooved joint. It may either be a drunken saw (*q.v.*) or a saw of thickness equal to the required groove running truly on its spindle.

Gros (*Silk Manufac.*) A coarse form of tabby, the bolder effect of cord being obtained by two or more picks passing into the same shed.

Grossularite (*Min.*) A calcium aluminium garnet (*see* GARNET), greenish or yellow, translucent. Composition approximately, $Si = 40$, $Al_2O_3 = 15$, $Fe_2O_3 = 10$, $CaO = 33$ per cent, with a trace of magnesium. From Siberia and Norway.

Grotesques (*Art*). Pictures or systems of ornament representing fantastic subjects. Arabesques consisting of extravagant figures fancifully combined with foliage, etc.

Ground (*Mining*). The rocks round a lode, often termed COUNTRY ROCK or merely COUNTRY.

—— (*The Arts*). (1) A foundation, used either for support or display. (2) A surface, natural or pre-

pared, which serves as a basis, especially in decorative art. (3) The principal colour employed on a picture. *See also* MEZZOTINT *and* ETCHING (*under* ENGRAVING).

Ground Air. It is found that all soils contain air, the quantity varying with the porosity and nature of the strata. Thus, loose sands contain as much as 50 per cent., while the densest rocks are free from it. It is especially rich in carbon dioxide, derived from the oxidation of the organic matter, the amount of which increases with the depth. The oxygen decreases in quantity with the depth. Nitrogen is present in nearly the same proportion as in the atmosphere. Occasionally the ground air contains ammonia, various hydrocarbons, and nitric acid. Ground air is in continual movement, the causes being: (*a*) the diurnal changes of temperature, (*b*) rainfall, (*c*) variations in barometric pressure, (*d*) fluctuation of ground water. To ascertain the amount of ground air present in a soil, a burette is taken and filled with the soil. Water is allowed to pass through the burette until it reaches the surface, thus expelling all the air, then

$$\frac{\text{the amount of water}}{\text{the amount of dry soil}} \times 100$$

gives the percentage of air.

Ground Bass (*Music*). A musical phrase constantly repeated in the bass with varied harmonic devices at each repetition above.

Ground Glass. Glass whose surface has been ground or roughened by rubbing with fine sand or emery, etc. It serves as a semi-transparent screen in photography and in various optical devices.

Groundlayer (*Pot.*) Groundlaying is the process of laying an even coat of colour over the surface of pottery or porcelain. The glazed ware is first coated with an oil which is dabbed carefully to render the surface perfectly even. The colour, in the form of a fine powder, is then dusted over the oil, to which it adheres; it is then burnt in the requisite kiln.

Ground Mass (*Geol.*) The non-crystalline lithoidal or vitreous material of any eruptive rock in which the crystalline portions are embedded.

Ground Nut (*Botany*). A small West African plant, *Arachis hypogea* (order, *Leguminosæ*), of the pea family, whose seeds yield a valuable oil used as a substitute for olive oil, and (on the Continent) in soap making. The nut is known in England as MONKEY NUT, and in America as PEA NUT. In the latter country it is used extensively as food, being usually sold freshly roasted. The name Ground Nut is applied to it from the fact that the nuts or seeds grow underground.

Ground Water. If a hole is dug in any soil a point is reached at which the interstices are found full of water. This point denotes the level of the ground water. This varies considerably in different localities. In some instances it is only a few feet from the ground level, while in other cases it is many hundreds of feet. As with ground air, ground water is in continual movement. It also fluctuates in level, being largely influenced by rains.

Grouting (*Build.*) Filling up joints, holes with ironwork sunk into them, etc., with thin fluid mortar, which can be poured into the cavities.

Grove Cell (*Elect.*) *See* CELLS, PRIMARY.

Groynes (*Civil Eng.*) Barriers of masonry (or more often of wood) running out at right angles to the coast line to protect the beach from erosion by the waves.

Grummet *or* **Gromet.** Twisted rope or yarn, used for packing joints in iron work which have to be made watertight.

Guaiacol (*Chem.*) $C_6H_4 \langle {OH \atop OCH_3}$. Colourless prisms; melts at 28° C.; smells like creosote. Its alcoholic solution gives a green colour with ferric chloride. It occurs among the products of dry distillation of GUAIACUM RESIN, and in beech creosote. It can be prepared from pyrocatechin (*q.v.*) by heating with caustic potash and potassium methyl sulphate. Is used as a medicine in phthisis, as it is believed to aid in the destruction of the bacilli in the lungs.

Guaiacum (*Botany*). This resin, used in pharmacy, is obtained from the stem of *Guaiacum officinale* (order, *Zygophyllaceæ*) by incision or exudation. The heartwood is also used in medicine.

Guanidine (*Chem.*) $HN:C \langle {NH_2 \atop NH_2}$. A colourless crystalline solid, very soluble in water and alcohol; a powerful monacid base. It may be prepared by heating together cyanamide and ammonium chloride with alcohol at 100°, usually by heating ammonium sulphocyanate for twenty hours at 180° to 185° C., when a residue of guanidine thiocyanate remains, from which the base can be obtained by conversion into sulphate by sulphuric acid and precipitation with baryta water. Guanidine heated with dilute sulphuric acid yields urea and ammonia: baryta water decomposes it in a similar way. On treatment of its salts with sulphuric and nitric acids, NITRO-GUANIDINE, $HN \langle {NHNO_2 \atop NH_2}$, a white crystalline solid, is formed, which on reduction with zinc dust and acetic acid gives AMIDO-GUANIDINE (*see* HYDRAZINE), which yields DIAZO-GUANIDINE, nitrate with nitric acid and sodium nitrite. The diazo-compound yields azoimide (*q.v.*) on boiling with alkalis.

$$HN = C \langle {NH - N = N - NO_2 \atop NH_2}$$

$$= CN.NH_2 + {N \atop \| \atop N} \rangle NH + HNO_3.$$

An important decomposition product of albumins is ARGININE, which is guanidine aminovalerianic acid,

$$HN = C \langle {NH_2 \atop NHCH_2CH_2CH_2.CHNH_2.COOH.}$$

Creatine and creatinine (*q.v.*) are also guanidine derivatives.

Guanine (*Chem.*) 
(2-amido-6-oxypurine). A white amorphous powder which can be crystallised from an ammoniacal solution; insoluble in water and in alcohol. Occurs widely distributed in animal tissues; fish scales contain the crystallised calcium compound of guanine, and are used under the name of PEARL ESSENCE in making artificial pearls; guano contains considerable quantities of it, and serves as the chief source; it is also a decomposition product of nuclein (*q.v.*) It has been obtained synthetically by heating 6-oxy-2:8-dichlorpurine with alcoholic ammonia and re-

duction of the chlorguanine thus produced by hydriodic acid. *See* PURINE. Treated with nitrous acid it yields XANTHINE (*q.v.*); on oxidation with hydrochloric acid and potassium chlorate it yields guanidine and parabanic acid (*q.v.*); unites with both acids and bases to form salts.

Guano. The dung of sea birds, found in large deposits upon the coast of South America. The Chincha islands are the principal sources of the Peruvian guano. It forms a valuable manure.

Guard Plate (*Eng.*) A dish shaped piece of metal fixed over the rubber disc of an indiarubber valve, convex side downward, so as to regulate the height to which the valve disc can rise.

—— (*Met.*) The perforated plate at the top of the tuyere box through which the blast passes into the bottom of a Bessemer converter.

Guard Rail (*Eng.*) A short rail laid parallel to an ordinary (railway) rail to guide the wheels of the vehicles where points and crossings occur; the guard rail comes into contact with the flanges of the wheels if the latter tend to leave the rails.

Guard Ring (*Elect.*) A wide ring of metal surrounding a flat plate, so as to form a surface practically continuous with the plate; used in the Attracted Disc Electrometer to ensure a uniform distribution of electricity over the surface of the disc.

Guards (*Bind.*) Narrow strips of paper inserted between the leaves at their backs, *e.g.* in albums, scrapbooks, etc., so that when the book is filled with photographs, or the pieces pasted on the leaves, the fore-edge shall not be thicker than the back. Guards, consisting of narrow strips of linen, are also employed for firmly securing plates in books, the plate being attached to the guard by means of some adhesive substance.

Gudgeon (*Eng.*) The shaft at right angles to a piston rod, to the ends of which the SLIPPER BLOCKS (*q.v.*) are attached.

Gudgeon Pin (*Eng.*) A connecting pin such as that which connects the connecting rod to the piston in gas or petrol engines. It serves as the axis about which the rod swings as it follows the motion of the crank.

Guide (*Eng.*) Any device by which an object is caused to follow a definite path; it is a term of very wide application.

Guide Bars (*Eng.*) The straight bars which cause the SLIDE BLOCKS or SLIPPER BLOCKS (*q.v.*) of an engine to move in a straight line, and so prevent the connecting rod from straining the piston rod, in consequence of its obliquity, as it follows the motion of the crank. *See* STEAM ENGINE.

Guide Pulley (*Eng.*) A loose pulley (*i.e.* one which revolves freely on its own axle or shaft), used to guide or steady a driving belt, etc.

Guide Screw (*Eng.*) The LEADING SCREW (*q.v.*) of a screw cutting lathe.

Guignet's Green (*Dec.*) One of the most permanent greens known. It is made by heating boracic acid and bichromate of potash, and is usually known as CHROME GREEN. A mixture of Prussian blue and chrome yellow is often sold for this pigment.

Guilloche (*Architect.*) An ornament used on the torus in classical architecture, and consisting of two or more interlacing bands.

Guillotine (*Bind. and Paper Trades*). A machine for cutting book edges, paper, etc., by action of a descending knife on the compressed material. It is named after the celebrated instrument of French capital punishment, and has almost superseded the plough and cutting press in bookbinding.

Guinea Corn (*Botany*). *See* DHURRA.

Guitar. *See* MUSICAL INSTRUMENTS—STRING (BY HAND).

Gules (*Her.*) The colour or tincture red; abbreviated to "gu"; expressed in engravings by perpendicular lines. *See* HERALDRY.

Gulf Stream (*Meteorol.*) The warm current flowing across the North Atlantic from S.W. to N.E. It produces considerable effect on the climate of north-west Europe, which would otherwise be much colder during the winter months.

Gullet. *See* SAW GULLET.

Gulleting (*Carp., etc.*) Filing out and deepening the hollow between the teeth of a circular saw. *See also* SAW GULLET.

Gully (*Build.*) A trap or cesspool into which waste and rain water pipes discharge.

Gum. *See* WOODS.

—— (*Chem.*) Gums are amorphous, transparent carbohydrates, which form a mucilage with water; insoluble in alcohol; heated with dilute acids they yield sugars, and oxidised by nitric acid they yield oxalic or mucic acids.

Gum Animé. A valuable copal gum principally received from Zanzibar. Its sp. gr. is 1·068, and the melting point 450°F. It sells on the London market from two hundred to three hundred and fifty pounds per ton.

Gum Arabic *or* **Gum Acacia.** The gum is an exudation from the stem and branches of *Acacia Senegal* (order, *Leguminosæ*) during the dry season. It forms rounded masses or "tears" of a yellowish colour, often transparent. Its principal constituent is ARABIC ACID or ARABIN $(C_6H_{10}O_5)_2 + H_2O$, a white amorphous solid. Boiled with dilute sulphuric acid, gum arabic yields much galactose (*q.v.*) It is used in medicine.

Gum Benzoin. *See* BALSAMS.

Gum, Black. *See* WOODS.

——, **Blue.** *See* WOODS.

——, **British.** *See* DEXTRINE.

Gum Copal. A generic term applied to a large class of gum resins, including hard copals from India and the east coasts of Africa. Copals are much used in varnish making, and possess the property of not dissolving unless previously fused.

Gum Dammar *or* **Damar** (*Dec.*) A soft gum used in varnish making. There are several varieties, one being white, the others nearly black. The gum is too soft to make oil varnishes, but is frequently mixed with turpentine in about equal proportions for special varnishes.

Gum Elemi. A balsam used in varnish making. It possesses a peculiar property of softness, and may be cut by a knife. It melts at 80° F., is partially fluid at 100°, and wholly so at 200°.

Gum, Kauri. A semi-fossil gum, much used in recent years in varnish making, particularly for oak varnish. It exudes from a pine tree found in New

Zealand (*Dammara Australis*). It unites with linseed oil quicker and at a lower temperature than any other resin. The melting point is 380° F. to 460° F., and the sp. gr. 1·070 to 1·080.

Gum Mastic. This gum oozes in the shape of tears from cuts made in trees. It is used for making the colourless varnishes employed by artists to preserve oil paintings, and possesses the advantage that it may be removed with facility when discoloured by age or dirt, as the resin is readily soluble in alcohol or turpentine.

Gumming of Oils (*Dec., etc.*) A condition of "drying" oils (such as linseed oil) which have been exposed to the air and have become thick or gummy by absorption of oxygen. In this condition they are not fit for painter's use in the ordinary way; but gummed oils are sometimes added to refuse paint which is thinned and reground.

Gum Pot. A vessel in which gum is melted in the manufacture of varnish (*q.v.*)

Gum, Red. *See* WOODS.

——, Sandarac. A resin which exudes from the *Callitris quadrivalvis*. It is hard but brittle, smells slightly of turpentine, and melts at 135° F. Used for special varnishes in combination with other gums.

——, Sweet. *See* WOODS.

——, Tasmania. *See* WOODS.

Gum Thus. The best quality of crude turpentine (*q.v.*)

Gum Tragacanth. Derived from various species of *Astragalus*, and is used largely in calico printing. It also forms an ingredient of various agglutinants, such as a paste for sticking labels on a smooth surface.

Guncotton *or* **Pyroxylin** (*Chem.*) $C_{12}H_{14}(NO_3)_6O_4$; also called CELLULOSE HEXANITRATE or NITRO-CELLULOSE. A solid not unlike cotton in appearance; insoluble in water, alcohol, ether; soluble in ethyl acetate. It is prepared by the action of a mixture of nitric acid and sulphuric acid on pure cotton; the time of immersion is short, and the product must be exceedingly well washed with water. The product is a true nitrate and not a nitro compound, because alcoholic potassium hydrosulphide gives cotton and potassium nitrate when digested with guncotton. It burns readily and so quickly that it may be ignited safely on the palm of the hand. When struck by a hammer on an anvil, the part struck alone detonates. Compressed guncotton is detonated by mercury fulminate (*q.v.*), and this is the way it is detonated in practice. In air it is burnt completely to carbon dioxide, water, and nitrogen; when fired in closed vessels, as it does not contain sufficient oxygen for its own combustion, carbon monoxide and hydrogen are also produced. The gases produced on firing measure (at 0° and 760 mm.) about 700 times the volume of the guncotton, and the temperature generated is exceedingly high—probably over 3000° C.

Gun Metal (*Eng.*) An alloy of copper and tin (often 9 copper to 1 tin). Used for bearings, small castings requiring a good finish, parts of electrical machinery which must be non-magnetic, etc.

Gunpowder. An intimate mixture of potassium nitrate, sulphur, and charcoal. The nitrate and sulphur are especially purified, and the charcoal is made from a soft wood, dogwood (*Cornus*). The proportions vary slightly but may be taken as very nearly 75 parts of nitrate, 15 of charcoal, and 10 of sulphur. The materials are mixed in a moist state, pressed into a cake, and granulated in a special machine, and then polished—the small grain powder, by simple friction of the grains against each other, the large grain by addition of graphite (black lead). Gunpowder explodes about 300° C.; the rate of explosion depends on the pressure under which it is fired; under very low pressures it will not explode at all. The principal gaseous products of its explosion are carbon dioxide, nitrogen, carbon monoxide, hydrogen, sulphuretted hydrogen, and marsh gas. The hydrogen is furnished by the moisture in the powder and gases occluded in the charcoal used in its manufacture. The principal solids are potassium carbonate, sulphate, sulphides, and sulphocyanate. The volume of gas produced is about 300 times that of the powder, the gases being measured at 0° and 760 mm.; the temperature is estimated at about 2000° C., and the pressure produced varies with the ratio of the volume of powder to the capacity of the containing space. When this ratio is 1, the pressure is about 42 tons to the square inch.

Gurgoyle (*Architect.*) *See* GARGOYLE.

Gurjun Balsam. A resinous exudation from the base of the stem of *Dipterocarpus lævis* (order, *Dipterocarpaceæ*). It is used as a varnish under the name of WOOD OIL. The tree is a native of the East Indies.

Gusset (*Arm.*) Portions of chain mail used in plate armour at the joints, *e.g.* armpits and ankles, to allow of greater freedom than a plain hinge could afford.

—— (*Eng.*) A bracket or stay used to strengthen the joint between two surfaces which meet at an angle, the gusset being in a plane at right angles to both.

—— (*Her.*) An abatement of honour; portions cut out from the side of a shield. An ancient charge fallen into disuse.

Gusset Plate (*Eng.*) A much used form of end stay for boiler plates and heads, being corner plate stays as opposed to stirrup and rod stays. They should always be joined by double angles with rivets in double shear, not less than 4 in. apart. In reason, the greater the distance apart the better, in order to afford "play or breathing" and avoid grooving (*q.v.*)

Gut Bands (*Eng., etc.*) Driving belts of catgut are used with small and fast running machines, for belt driven motor cycles, etc.

Guttæ (*Architect.*) Small droplike ornaments formed on the soffit of the mutules and under the triglyphs in the Doric entablature. The guttæ in the Greek Doric entablature are much shorter than those used by the Romans. *See* CAPITAL OF GUTTÆ *and* ARCHITECTURE, ORDERS OF.

Gutta Percha. The saplike gum collected from various trees (*Sapotaceæ*) growing in the Indian Archipelago, but chiefly from *Dichopsis gutta*. It differs from rubber (caoutchouc) in being plastic, but not elastic; nor can it be vulcanised. It is collected from trees felled immediately after the rainy season. Owing to the fact that it is not affected by caustic alkalis or by dilute acids, gutta percha is used in the manufacture of syphons, funnels, and other chemical apparatus, while its acoustic properties render it suitable for stethoscopic and other aural instruments. It is also used to form driving bands for small

machinery, and extensively as an insulator in telegraphy. It is also the medium now used for making the blocks in electrotyping.

Guttée *or* **Gouttes** (*Her.*) From the Latin *gutta*, a drop. A field may be covered with gouttes. They are of several tinctures, *viz.* Guttée d'or, de larmes or d'eau, du sang, de vert or d'olive, and de poix.

Gutter (*Build.*) A channel to carry off the rain from a roof.

—— (*Print. and Bind.*) Another term for the "back" or inner margin of the printed page of a volume.

Gutter Bearers (*Build.*) The pieces that support the gutter boards.

Guttiferæ (*Botany*). A tropical Dicotyledon order whose timbers, resins, and fruits are of value.

Guy Rope. A rope that keeps a derrick vertical.

Guze (*Her.*) A roundlet of "murry" or "sanguine," blood colour; a charge now seldom used.

Gymnospermæ (*Botany*). A great division of the seed plants, differing from the flowering plants in the characters of the carpels and ovules. The Conifers are the best known members of the division.

Gynæceum (*Botany*). The term applied to the carpels of a flower.

Gypsum (*Min.*) Hydrous sulphate of calcium, $CaSO_4 . 2H_2O$. Lime = 32·6, sulphuric acid = 46·5, water = 20·9 per cent. Crystallises in the monosymmetric system (SELENITE). More often massive and granular in beds, or fibrous in veins. Can be scratched by the nail. Colourless to brown. It is used to some extent to harden the water in brewing, but chiefly to make plaster of Paris; for this purpose it is heated, to drive off water, and then ground. On the addition of water, hydration takes place and it sets. From many parts of England, and largely from Montmartre near Paris.

Gyration, Centre of. *See* PENDULUM.

Gyronny (*Her.*) A field divided into several parts of gyrons. A gyron is one of the ordinary divisions of a shield.

H (*Elect.*) (1) A general symbol for the MAGNETISING FORCE (*q.v.*) at a point; especially (2) the HORIZONTAL INTENSITY of the Earth's Magnetic Field. *See* HORIZONTAL FORCE.

—— (*Music*). The German name for B♮. Their B is our B♭.

Hacking (*Plast.*) Roughening the surface of a brick wall with a hammer to form a KEY (*q.v.*) for the plaster.

Hacking Hammer (*Plast.*) A plasterer's hammer, used for cutting away old plaster, etc.

Hackling (*Linen Manufac.*) The rough flax as it comes from the scutch mills requires to be combed to free it of all short and twisted fibres, and to split up all parcels of fibres that may be sticking together. The first hackling is called ROUGHING, then finer combs are used, or MACHINE HACKLES may take the place of finer hand hackles. After hackling, the flax is a nice straight silky fibre. *See* LINEN MANUFACTURE.

Hack Off (*Plast.*) To cut away old plaster with a hammer.

Hack Saw (*Eng.*) A narrow saw of hard steel stretched on a frame; used for cutting metals.

Haddock. A food fish of the cod tribe, *Gadus æglefinus* (family, *Gadidæ*), attaining a large size in northern seas, and eaten in a fresh or smoked condition.

Hade (*Geol.*) Originally a miners' term for the inclination measured from the vertical of the plane of a FAULT (*q.v.*) This varies very much in different cases, and may be different in various parts of the same fault if the rocks through which the fault passes happen to show a wide range in petrographical characters.

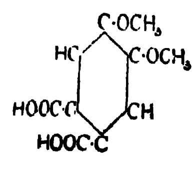
Hæmateïn (*Chem.*), $C_{16}H_{12}O_6$. Lustrous dark green solid, or, when powdered, a lustrous reddish brown powder; sparingly soluble in water and alcohol. It dissolves in ammonia with a purple colour. To obtain it, hæmatoxylin (*q.v.*) is cautiously oxidised by nitric acid. It is to the formation of this substance from the hæmatoxylin of logwood that the dyeing powers of the latter are due. With chromium and iron mordants it dyes black on silk, wool, and cotton.

Hæmatin (*Chem.*) *See* HÆMOGLOBIN.

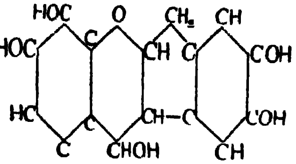
Hæmatite (*Min.*) Ferric oxide, Fe_2O_3. Iron = 70, oxygen = 30 per cent. Also called SPECULAR IRON. Rhombohedral. Crystals steel blue to black, blood red if very thin; massive varieties are blood red; both have a characteristic blood red streak. It is an important ore of iron, occurring in irregular replacement deposits in limestone or in calcite veins underlying rocks containing hæmatite in a disseminated state. The variety KIDNEY ORE is so called from the reniform shape of the masses. REDDLE is an earthy variety. SPECULAR IRON is so called from the mirrorlike surfaces of the crystals. Besides being used as an ore, this mineral is used in polishing and burnishing, both in the mass and when powdered. It occurs in large quantity in West Cumberland and North Lancashire, but much of the so-called hæmatite of this district is really a ferric hydrate related to Turgite (*q.v.*) Also in the south-west of England, in Elba, and in Missouri, U.S.A.

Hæmatoporphyrin (*Chem.*) *See* HÆMOGLOBIN.

Hæmatoxylin (*Chem.*), $C_{16}H_{14}O_6$. A colourless crystalline solid which becomes red on exposure to light; sparingly soluble in cold water, readily in hot water, in alcohol, and ether; it has a sweet taste; it is dextrorotatory. The *acid* solution is yellow; the alkaline solution is purple; the neutral solution is colourless. It is extracted from logwood by aqueous ether. On gentle oxidation it yields HÆMATEÏN (*q.v.*), and on this property the dyeing properties of logwood are based. In fusion with potash it yields RESORCIN (*q.v.*) and pyrogallic acid; it forms a penta-acetyl derivation. On oxidation of its tetramethyl derivative it yields, among other products, metahemipinic acid—



On these and other grounds Perkin proposes the formula



Hæmatoxylon (*Botany*). *H. campechianum*, a leguminous tree of tropical America, yields the logwood of commerce.

Hæmin (*Chem.*) *See* HÆMOGLOBIN.

Hæmochromogen (*Chem.*) *See* HÆMOGLOBIN.

Hæmocyanin (*Chem.*) A substance found in the blood of certain molluscs and crustacea. Like hæmoglobin it absorbs oxygen, but is turned to a beautiful blue colour by it; this is due to the fact that it contains copper instead of iron, which is contained in hæmoglobin. It is a proteid.

Hæmoglobin. The red colouring matter of the blood of vertebrates; it is the principal constituent of the red corpuscles. It may be obtained by adding salt to blood and separating the corpuscles by a centrifugal machine, then treating the corpuscles with a little ether. On allowing the ether to evaporate the hæmoglobin crystallises out. Hæmoglobin preparations from the blood of different animals show differences in solubility, in crystalline form, and in ease of crystallisation: that from most animals crystallises in prisms, but that of the guinea pig in octahedra. The hæmoglobin of rat or dog blood crystallises more readily than that from human blood. Chemically, hæmoglobin appears to be the same substance, whatever its source. Hæmoglobin contains carbon, hydrogen, nitrogen, oxygen, iron, and sulphur. It combines (molecule for molecule) with oxygen, carbon monoxide, and nitric oxide. In the blood it exists as hæmoglobin (sometimes called reduced hæmoglobin), and combines with oxygen to form oxyhæmoglobin. From its content in iron and its union with carbon monoxide a minimum molecular weight of 16,669 has been calculated for hæmoglobin, and from this value for its molecular weight and the percentage of its constituent elements the formula $C_{758}H_{1203}N_{195}O_{218}FeS_3$ has been calculated for it. As these results were obtained with pure recrystallised material, they are probably near the truth. It gives the same precipitation and colour reactions as the albumins (*q.v.*) Hæmoglobin is the oxygen carrier of the blood; in the lungs it is changed to oxyhæmoglobin, and the bright red colour of arterial blood is due to this compound. The oxyhæmoglobin gives up its oxygen to the tissues, and is reduced to hæmoglobin, the dark red colour of venous blood being due chiefly to hæmoglobin, but not entirely, as venous blood contains some oxyhæmoglobin. This absorption and giving up of oxygen can be imitated artificially. A bright red solution of oxyhæmoglobin gives up its oxygen under the receiver of an air pump, and changes to a dark red solution of hæmoglobin, or the same change can be brought about by passing a stream of an indifferent gas, such as nitrogen or hydrogen, through the oxyhæmoglobin solution; then, on exposing the hæmoglobin to air, or passing oxygen through it, the oxyhæmoglobin is reproduced. The compound of hæmoglobin with carbon monoxide (carboxyhæmoglobin) is produced when carbon monoxide is passed through a hæmoglobin solution. It has a cherry red colour, and is far more stable than oxyhæmoglobin, and is formed in the blood when air containing carbon monoxide is inhaled. Should half the hæmoglobin of the blood be transformed to carboxyhæmoglobin, death results; but when less than this amount is transformed, oxygen can still decompose the carboxy compound, and recovery follows. Hæmoglobin can combine with oxygen in a much more stable way than when it forms oxyhæmoglobin. This stable oxygen compound is called methæmoglobin, and it is formed when oxyhæmoglobin is allowed to stand; also by a large number of substances, some of which are oxidising agents (*e.g.* potassium chlorate and nitrate) and reducing agents (*e.g.* hydrogen and pyrogallic acid). Potassium ferricyanide—an oxidising agent—is generally used to produce methæmoglobin. It does not give up oxygen under reduced pressure, like oxyhæmoglobin. Ammonium sulphide and Stokes's reagent (a solution of ferrous sulphate and tartaric acid to which ammonia has been added) transform methæmoglobin first to oxyhæmoglobin, then to hæmoglobin. Hæmoglobin and all its derivatives mentioned above show characteristic absorption spectra. The carboxyhæmoglobin spectrum is used as a test for carbon monoxide in air, and though it rather resembles the oxyhæmoglobin spectrum, it is sharply distinguished from the latter by remaining unchanged on addition of ammonium sulphide to the solution under examination, while the oxyhæmoglobin spectrum changes to that of hæmoglobin. Hæmoglobin on treatment with dilute acid is resolved into an albumin globin and a substance hæmatin, which contains all the iron of the hæmoglobin. Hæmatin is obtained in the form of its crystallised hydrochloride, called hæmin (Teichmann's blood crystals), by treating coagulated blood corpuscles with amyl alcohol and hydrochloric acid. The formation of these crystals constitutes the most reliable test for a stain supposed to be due to blood. On treatment with caustic soda and precipitation with hydrochloric acid, hæmin yields hæmatin as a blue black amorphous solid, which is easily soluble in alkalis and in acidified alcohol. Its solutions show different absorption spectra according as they are alkaline or acid, the acid spectrum resembling that of methæmoglobin. Like hæmoglobin, hæmatin can combine with oxygen; in fact, the oxygen compound is generally called hæmatin, while the oxygen free compound is called reduced hæmatin or hæmochromogen. When hæmatin hydrochloride (hæmin) is treated with an acetic acid solution of hydrogen bromide, and the solution gently warmed, a compound called hæmatoporphyrin is formed. This substance has the formula $C_{34}H_{38}O_6N_4$: the hæmatin has given up iron. From both hæmatoporphyrin and hæmatin there is obtained by oxidation the anhydride of the tribasic hæmatinic acid, which is identical with methyl-β-carboxyethyl maleic acid anhydride:

$$\begin{array}{rl} CH_3.C & -\ CO \\ \Vert & \quad > O \\ COOH.CH_2CH_2\ C & -\ CO \end{array}$$

From hæmatin by reduction with hydriodic acid and phosphonium iodide there arises first mesoporphyrin, $C_{34}H_{38}O_4N_4$, and then hæmopyrrol, which is ββ'-methylpropylpyrrol, and yields on oxidation methylpropyl malcic acid imide:

$$\begin{array}{rl} CH_3.C & = CH \\ \vert & \quad > NH \\ CH_3.CH_2.CH_2.C & = CH \end{array} \longrightarrow \begin{array}{rl} CH_3.C & - CO \\ \Vert & \quad > NH \\ CH_3.CH_2.CH_2.C & - CO \end{array}$$

See PHYLLOPORPHYRIN.

Hagioscope (*Architect.*) An oblique opening frequently found on one or both sides of the chancel arch in a church to enable persons in the aisles and transepts to see the performance of certain ceremonies at the altar. These openings are also known as SQUINTS.

Ha-ha (*Architect., etc.*) A boundary fence sunk in a hollow.

Hail (*Meteorol.*) Ice crystals forming masses very much denser than snow. They are caused by rain drops becoming frozen in their passage through the air. Sections of them show that they pass through several distinct cold air strata.

Hailstones (*Meteorol.*) Are generally of a conical or round form, and when cut across are composed of layers of clear and opaque ice with a snowy nucleus. They vary in size from a small shot to several inches in diameter. *See* HAIL.

Hair Compass (*Eng.*) A small pair of spring compasses with a fine adjustment actuated by a set screw.

Hairline (*Textile Manufac.*) A fine STRIPE made in woollen and worsted YARNS. A standard fabric in the west of England.

Hairline Letter (*Typog.*) A very thin-faced type, often used for lettering mounts.

Hair Pencil (*Paint.*) A painter's brush; the hairs are generally mounted in a quill for watercolours, and in a metal tube for oils.

Hair Side (*Leather*). The side of a skin on which the hair grew, *i.e.* the outer side.

Hair Space (*Typog.*) The thinnest space used by printers, often used for spacing headlines of books.

Hair Spring (*Watches*). *See* BALANCE SPRING.

Hake (*Zoology*). A food fish of the cod tribe, *Merluccius vulgaris* (family, *Gadidæ*), found largely on the coast of Cornwall. The flesh is eaten fresh or salted.

Halation (*Photo.*) A blurring of the image; an encroachment of the high lights on the darker portions next to them; caused by reflection from the back of the plate. In order to prevent this, some material is applied "in optical contact with the glass" which will absorb those rays that act chemically upon the sensitive surface. The substance which answers best is probably asphaltum.

Halberd *or* **Halbert** (*Arms*). A weapon used during the fifteenth and sixteenth centuries. It consisted of an axe with a spike or spearhead at one end, the other end being attached to a handle or staff about 6 ft. long and in line with the spike. Subsequently it was used by bodyguards for display.

Halecret, Allecret (*Cost.*) Light plate armour forming two corslets, lighter than a cuirass, and worn alike by horsemen and footmen in the sixteenth century.

Half Bound (*Binding*). Books with leather backs and corners and cloth or marbled paper sides, as distinguished from books wholly covered in leather.

Half Case (*Typog.*) A small case used for jobbing work.

Half Centre (*Eng.*) The position of an engine crank when at right angles to the line of the piston rod.

Half Close (*Music*). Another term for imperfect cadence. *See* CADENCE.

Half Lap Coupling (*Eng.*) Two shafts connected by a half lap joint (*q.v.*)

Half Lap Joint (*Eng., Carp., etc.*) A joint in two pieces of material which are in the same straight line with each other, the joint being formed by cutting away a portion of the material in each of the parts to be joined; the portion removed is equal to half the thickness of each of the members. Also termed HALVING.

Half Length (*Art*). A portrait representing only the upper half of a person.

Half Period Zones (*Light*). In order to deal with the problem of illumination at a given point due to a light wave from a luminous source, it is convenient to divide up the advancing wave front into small portions known as half period elements or zones. Let b be the perpendicular distance from the given point to the wave front. Then if λ be the wave length of the light in question, a curve may be drawn on the wave front through all the points whose distance from the given point is $b + \frac{1}{2}\lambda$. The area included in this curve is the first half period element. Let the process be repeated for points whose distances from the given point are $b + \frac{2\lambda}{2}$, $b + \frac{3\lambda}{2}$, etc., in this way marking out a series of annuli which constitute the second, third, fourth, etc., elements. In the case of a spherical wave, these elements are all of equal area, and their usefulness depends upon the fact that the wave disturbance at the given point due to any element is, on the whole, in opposition to the effect of the next consecutive element, and thus the effect of the whole wave can be expressed in terms of these half period components.

Half Plain Work (*Build.*) The labour expended on the bed and side joints in stone walling.

Half Plate (*Photo.*) A plate measuring $6\frac{1}{2}$ in. by $4\frac{3}{4}$ in.

Half Portees (*Silk Manufac.*) *See* PORTEE.

Half Rip Saw (*Carp. and Join.*) A saw used by joiners for cutting wood in the direction of its fibres. It has about three to four and a half teeth to the inch. *See* SAWS.

Half Round File (*Eng.*) A file flat on one side and convex on the other.

Half Secret Dovetail (*Join.*) A dovetail of the form used in a drawer front; it is concealed in a front view, but visible in the side of the drawer when drawn out.

Half Shrouding (*Eng.*) A flange on a spur wheel which extends up to the pitch line, or half the depth of the teeth. *See also* SHROUDING.

Half Space (*Carp. and Join.*) A landing equal in size to the width of the staircase.

Half Stuff (*Paper Manufac.*) A name given to partially beaten pulp obtained during the manufacture of paper.

Half Timbered Work (*Build.*) Buildings in which the walls are formed of frames of timber, the panels being filled in with brickwork. *See also* FRAME HOUSES.

Half Tint. *See* HALF TONE.

Half Title (*Typog.*) The sub-title: it precedes the full title in a book.

Half Tone (*Art*). A tone intermediate between the most marked tones in a picture, etc., *i.e.* between the extreme lights and the extreme shadows; the lighter shadows of a picture, photograph, etc.

Half Tone Block. *See under* PROCESS WORK.

Half Wave Plate (*Light*). A plate of doubly refracting crystal, capable of splitting up a plane polarised ray into two portions, one of which is retarded half a wave length with respect to the other.

Hall Effect (*Phys.*) Suppose a steady current is flowing through a very thin metal plate, and let two points, transversal to the line of flow, be connected to a galvanometer. These points of contact can be adjusted until there is no deflection, showing that they are on the same equipotential line. Hall discovered that under these circumstances a deflection of the galvanometer is produced if the plate be placed in a strong magnetic field at right angles to the lines of force, which shows that an alteration takes place on the stream lines of current in the plate. The direction of the transverse E.M.F., which produces this effect, varies with the metal used; in iron, antimony, and zinc its direction coincides with the direction of the mechanical force exerted by the field upon the plate carrying the current, and the opposite is the case in bismuth, gold, and nickel. The magnitude of the E.M.F. is proportional to the strength of current in the plate, to the strength of the magnetic field, and inversely proportional to the thickness of the plate, and in any case is small and difficult to observe. The effect is almost certainly due to the deflection of the moving carriers of the current or "electrons" (*q.v.*), and is intrinsically the same as the more easily observed deflection of the "cathode rays" by a magnetic field.

Halogens (*Chem.*) The four elements, FLUORINE, CHLORINE, BROMINE, and IODINE are called the HALOGENS. They all form salts with sodium and potassium, and these salts bear a resemblance to sodium chloride, hence the name, which means literally sea-salt producers.

Haloid Salts (*Chem.*) The fluorides, chlorides, bromides, and iodides of the metals. In organic chemistry the compounds formed by the union of the halogens with alcohol radicals are often called HALOID ESTERS.

Halos (*Meteorol.*) Large circles formed round the moon or sun when viewed through light clouds. They are due to refraction, and may be either white or prismatic (rainbow coloured). Sometimes bright circles are formed on them, termed MOCK SUNS or PARHELIA, and MOCK MOONS or PARASELENÆ.

Halving (*Carp., etc.*) *See* HALF LAP JOINT.

Hamamelidaceæ (*Botany*). A subtropical natural order allied to the *Rosaceæ*. Its species yield woods (*Liquidambar*), resins (*Storax*), and medicinal products (*Hamameli*, witch hazel). *See also* SATIN WALNUT, *under* WOODS.

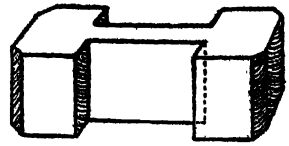
Ham Hill Stone. *See* BUILDING STONE.

Hammer. *See* HAMMERS.

Hammer Beam (*Carp. and Join.*) *See* ROOFS.

Hammer Dressed (*Build.*) Stones roughly shaped with a hammer at the quarry.

Hammer Headed Key (*Carp. and Join.*) A key with a projection for wedging. Its general form is as shown in the figure.



HAMMER HEADED KEY.

Hammerman (*Eng., etc.*) (1) The workman who manipulates the steam hammer in a forge. (2) An assistant to a smith, who uses a double handed or sledge hammer. (3) One of a set of men in a coal mine who fall the coal by means of wedges driven into holes. Also known as a DRIVER.

Hammers. A hammer consists of a suitably shaped HEAD of iron, steel, or iron faced with steel, provided with a handle or shaft of ash, lancewood, or some similar wood possessing strong springy fibres. Hammers vary in size, from those used by watchmakers up to the heavy sledge hammer weighing 14 lbs. or more. The most usual form has a flat surface or FACE at one end of the head, used for striking a blow; the other end of the head is formed into a PANE (also termed PEEN, PENE, or PIN), and is modified into many different forms for special purposes. A and B (fig. 1) are ordinary JOINERS'

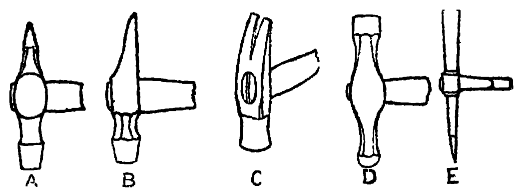


FIG. 1.

HAMMERS; C is a CLAW HAMMER, in which the pane is formed into a claw possessing a V-shaped slot used for drawing out nails. D and G are hammers with a BALL PANE, used by engineers and smiths. E is a form used by upholsterers; various modifications of this form are also used in allied trades. F is a DOUBLE HEADED HAMMER, used for

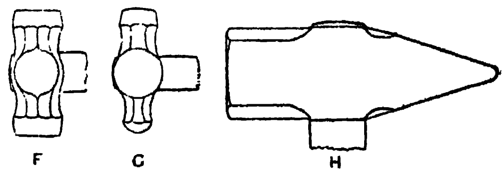

FIG. 2.

many different purposes, *e.g.* by joiners for driving home the tenons in a piece of framing, and termed by them a FRAMING HAMMER. H is a SLEDGE HAMMER, which may be made double headed, or may have a pane with its edge parallel to the handle (STRAIGHT PANE) or at right angles to the handle (CROSS PANE). A sledge hammer is provided with a long handle, and is usually wielded by a hammerman or striker, who uses both hands to swing it, the tool or work which is to be struck being held and manipulated by the smith or other workman. In addition to the hammers here described, a variety of forms are used by tin and copper-smiths, artistic workers in metal, and in many other arts and trades.

Hammer Scale (*Eng.*) The oxides of iron formed on the surface of iron in the forge, rolling mills, etc. The scale contains two oxides, FeO and Fe_2O_3, in varying proportions.

Hanap (*Archæol.*) A mediæval wine cup or goblet, often made of precious metal highly decorated.

Hand (*Her.*) A charge often borne in heraldry. The Badge of Ulster is a bloody hand. *See* ULSTER.

Hand Camera (*Photo.*) A camera that is held in the hand while photographing the subject. Fitted with a quick acting lens and shutter, and provided with either a set of dark slides, roll film holder, or a receptacle capable of containing plates or films, and a device for changing these after each successive exposure without the use of a dark-room.

Hand Feed (*Eng.*) The regulation of the rate of cutting in machine tools by the hand of the operator, as opposed to automatic or POWER FEED.

Hand Float (*Plast.*) A rectangular wooden blade with a "hand" fixed to it. Used for "floating," *i.e.* levelling and smoothing the surface in plastering.

Hand Holes (*Eng.*) Small holes in boilers, etc., through which the hand can be inserted for cleaning out the interior.

Hand Ladle (*Foundry*). A ladle for carrying molten iron; small enough to be carried by one man, and holding about fifty pounds weight of iron.

Hand Letters (*Bind.*) Alphabets of letters cut on brass stems set in wooden handles for "lettering" or placing the titles on the backs of books. They are used singly, but brass type can be set in a line.

Hand Machines (*Eng.*, *etc.*) Small machines driven by hand as distinguished from those driven by power.

Hand Made Paper. Paper made entirely by hand. It is of better quality and more expensive than machine made paper. *See* PAPER MANUFACTURE.

Handrail (*Joinery*). The rail running along a staircase, landing, etc. Handrails are spoken of as RIGHT or LEFT, according to which hand rests naturally on the rail when *ascending* the staircase.

Handrailing (*Joinery*). (1) A HANDRAIL (*q.v.*) (2) The process of designing and constructing handrails.

Handrail Punch. A punch for tightening up a handrail screw (*q.v.*)

Handrail Screw (*Joinery*). A small screw or bolt used in making a joint between two lengths of handrail. The nut is cylindrical, and possesses grooves or notches in its periphery, into which a handrail punch is inserted through an opening in the undersurface of the rail, in order to turn the nut and screw it up so as to make a tight joint.

Hand Rest (*Eng.*) The T-shaped rest for supporting hand-turning tools in working at a lathe when a slide rest is not used.

Hand Roller (*Typog.*) The roller sometimes used to ink type by hand when pulling a proof.

Hand Saw. A carpenter's tool for cutting timber across its fibres (grain). It has about five teeth to the inch. *See* SAWS.

Hand Screw (*Joinery*, *etc.*) A wooden cramp worked by two handles with threads on them. Used for holding glued work in position while the glue is setting.

Hand Tools (*Eng.*) Those which can be held in the hand or which are actuated by hand.

Hanger *or* **Hang Down** (*Eng.*) A frame for suspending a bearing from a roof or beam.

—— (*Foundry*). The sling which supports heavy weights in the foundry; the upper ends of the rods of the sling are attached to the travelling crane.

Hanging Committee (*Art*). A committee charged with the duty of hanging the pictures selected for an exhibition. At the Royal Academy the hanging committee consists of eight Academicians, including one sculptor and one architect.

Hanging Steps (*Build.*) Stone steps having one end built into a wall.

Hanging Style (*Carp. and Join.*) The style of a door which has the hinges fixed on to it.

Hank (*Linen Manufac.*) A hank is a bunch of reeled yarn, usually containing 12 cuts of 300 yards each in Ireland; in England 10 cuts of 300 yards are made up as hanks. *See* CUT.

—— (*Textile Manufac.*) The number of yards which determines the counts or thickness of a thread. COTTON and SPUN SILK HANKS contain 840 yards; a WORSTED HANK, 560 yards.

Hannay's White Lead (*Dec.*) A brilliant white pigment almost non-poisonous. It is produced in the form of a very fine powder direct from galena or lead ore. Made by volatilising the galena and passing it through oxidising chambers, whence lead sulphate is formed in fumes. The pigment is claimed to possess superior qualities to ordinary white lead (*q.v.*) made by the Dutch Process.

Harbour (*Civil Eng.*) An anchorage for ships, usually formed by a natural opening in the coast line, protected if necessary by artificial barriers or breakwaters.

Hard Brass (*Met.*) Brass which has not been annealed, or which has been hammered; it is much more elastic than soft or annealed brass.

Hard Core (*Build.*) Broken bricks, etc., used for filling up cavities, the foundations of roads, and similar purposes.

Hardening (*Met.*) Applied to steel it refers to the process of heating and sudden cooling which gives the maximum amount of hardness to the metal. This is afterwards modified by TEMPERING (*q.v.*)

Hardening Liquids (*Eng.*) The liquids used in cooling steel to harden it. Pure water, oils, and water with various salts dissolved in it are used; the advantages of the latter are very doubtful.

Hard Iron (*Eng.*) Castings of suitable brands of pig iron, mixed with scrap iron, can be made specially hard for use in parts of machines subject to much friction and wearing, such as wheel teeth.

Hard Kiln (*Pottery*). This is of the form of the enamel kiln, *viz.* muffle, but it is fired at a temperature between that of the enamel kiln and the glost oven.

Hard Lead (*Eng.*, *etc.*) Lead containing various impurities (antimony, etc.) becomes much harder than pure lead, and is useless for many purposes.

Hardness (*Min.*) The hardness of a mineral is determined by noting which of the standard minerals

the specimen may be scratched by, and which of the ten it will scratch. The standards are:

(1) Talc.	(6) Felspar.
(2) Gypsum.	(7) Quartz.
(3) Calcite.	(8) Topaz.
(4) Fluorspar.	(9) Sapphire.
(5) Apatite.	(10) Diamond.

Hardness (of Water). *See* WATER, CALCIUM COMPOUNDS, CLARK'S PROCESS, *and under* SANITATION.

Hard Packing (*Typog.*) A system of "making ready" (*q.v.*) which dispenses with the blanket, and is chiefly employed in printing on calendered papers. Illustrated magazines are generally printed by this system.

Hard Paste (*Pottery*). The term "Hard Paste" implies the reverse of Soft Paste. The body is more natural in its composition. The bisque is burned at a low temperature, leaving it porous and non-translucent. After glazing it is burned at a high temperature, which melts the glaze into the body. The body is thus rendered *non-porous* and *translucent*; the glaze is "hard" and is absorbed into the body.

Hard Paviors (*Build.*) Malm bricks, over-burnt and slightly blemished in colour, used for paving, coping, etc.

Hard Solder (*Eng., etc.*) Various alloys containing silver, copper, zinc, etc., used in brazing (*q.v.*), in soldering jewellers' work, and other purposes where a very close, neat, and strong joint is required. The difference between hard and soft solders is chiefly due to the absence of lead in the former: consequently the melting point of hard solders is much higher.

Hard Stock. *See* BRICKS.

Hard Water. *See* WATER, CALCIUM COMPOUNDS, CLARK'S PROCESS, *and under* SANITATION.

Hard Woods (*Carp., etc.*) This term is loosely applied to most woods, other than the coniferous woods (pine, deal, etc.), but it has no exact significance. *See* WOODS.

Hargreave's Process (*Chem.*) A process for the direct conversion of common salt into sodium sulphate without the intervention of sulphuric acid. Sulphur dioxide, air, and steam are passed over cakes of common salt contained in iron cylinders, kept at a temperature of about 500° C. The gases are passed over the salt in such a manner that the freshly introduced gas comes in contact with salt which is nearly converted; and the gases which are nearly used up, with fresh salt. The sulphur dioxide is obtained by burning iron pyrites.

Harmonic Curve (*Phys.*) The curve obtained when simple harmonic motion is represented by plotting time as abscissæ and displacements from zero position as ordinates. It may also be defined as the curve obtained by compounding a S.H.M. in a given direction with a uniform linear motion in a perpendicular direction. The simplest form of the equation to the curve is $y = a \sin bx$, where a represents the maximum amplitude and $\frac{2\pi}{b}$ the periodic time, and hence it is known as a "sine" curve. Its great importance and usefulness depend on the fact (discovered by Fourier) that any periodic curve whatever may be analysed into a series of superposed harmonic curves, and thus made amenable to calculation. *See* FOURIER'S SERIES *and* HARMONIC MOTION.

Harmonic Law (*Astron.*) The name of the third law of motion discovered by Kepler in the seventeenth century; namely, the squares of the periods of the planets are proportional to the cubes of their mean distances from the sun.

Harmonic Motion, Simple (*Phys.*) A type of oscillatory motion deriving its name from its very general occurrence in the vibrations of bodies emitting musical sounds when the amplitude is not too great. It is completely defined by the two conditions: (1) the acceleration of the moving mass is proportional to its displacement; (2) the acceleration is always acting towards the position of rest. The time of one complete vibration is given by $T = 2\pi\sqrt{\frac{\text{Displacement}}{\text{Acceleration}}}$, and above definitions show that this is a constant quantity. As instances of motions of this type may be mentioned the point of the prong of a tuning fork, or a point in a vibrating string; vibrations of a weight suspended by a spring; oscillations of a pendulum, etc.; it being assumed in each case that the amplitude is small. The resultant of two harmonic motions at right angles, of the same period and amplitude, but differing in phase by a quarter of a period, is a uniform circular motion, and hence arises a simple method of representation. For if a point P (fig. 1) be supposed to move with uniform velocity in a circle (termed the CIRCLE OF REFERENCE) whose radius OA is equal to the AMPLITUDE of the vibration (where amplitude = maximum displacement from position of rest), the point X, or foot of the perpendicular from this point upon the diameter AB, moves backwards and forwards with a simple harmonic motion in the time of one complete revolution of P: this time is termed the PERIODIC TIME, and usually denoted by T. We may express the same facts in mathematical symbols as follows: The distance OX (which may be denoted by x), termed the DISPLACEMENT, is equal to OA cos AOP, or $r \cos \theta$. Now θ is the angle through which the line OP has turned in a given time; let this time be t, and let the angular velocity of OP be ω. Then $\theta = \omega t$, and $x = r \cos \omega t$. The displacement may therefore be represented by a curve, of which the abscissa is proportioned to t and the ordinate to $\cos \omega t$. A similar curve in which the ordinate is proportional to Sin ωt is shown in fig. 2.

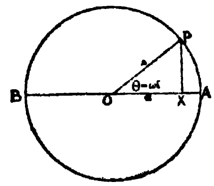

FIG. 1.

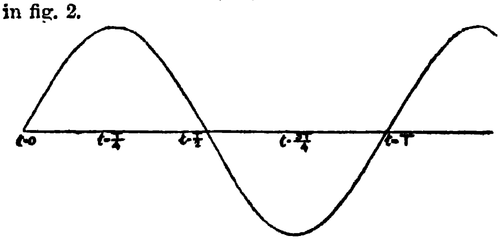

FIG. 2.

The displacement is zero when $t = 0$; it increases to a maximum which is equal to r, the amplitude, when $t = \frac{T}{4}$ (that is, after a quarter of a revolution of the

point P), and falls to zero again when $t = \frac{T}{2}$, or when P is at B (fig. 1), and then attains the value $-r$ when $t = \frac{3T}{4}$, returning to zero after an interval T, when P has again reached A. This curve is a SINE CURVE (or COSINE CURVE). The angle which OP makes at any given instant with some arbitrary fixed line is termed the PHASE of the point which is executing the simple harmonic vibration. Thus if we take OA as the fixed line, the phase of the point X is the angle POA, which equals θ or ωt.

Harmonics (*Music*). (1) The series of constituent sounds of higher pitch which are produced with more or less completeness along with a musical tone, and which play an important part in determining the "quality" of musical tones. They are also called "overtones" or "upper partials." These harmonics are given forth in a regular progressive series, each note being of less intensity than the preceding. In the following table of the first 19 harmonics produced from the note D it will be seen that the vibration ratio of each note is one half that of its octave:

The harmonics given off by the $\frac{1}{7}$th and $\frac{1}{14}$th of the whole string are slightly flatter, and that given by the $\frac{1}{11}$th sharper, than the corresponding exact note of the key. (This table is taken from Professor Prout's *Harmony*, chap. ii.) This series of harmonics may be produced theoretically along with every note, and by transposing this table according to the generator required the series may be found from that note. (2) Upper notes produced on stringed instruments—(*a*) by slightly pressing the finger on the open string at the various "nodes," *i.e.* points of rest in a vibrating string. These are termed NATURAL HARMONICS. (*b*) By stopping the string with the first or second finger, and then slightly pressing the node with the fourth finger. These are termed ARTIFICIAL HARMONICS. These harmonics are written in diamond shaped notes.

—— (*Phys.*) In almost all cases of vibration it is more or less difficult to obtain a single definite frequency. As a rule, smaller vibrations are present superposed upon the original or fundamental. These are known as the "harmonics," and first acquired importance in the theory of sound and of music. It is now usual to define the harmonics of any vibration as a series of vibrations having frequencies 1, 2, 3, 4, 5, etc., times the frequency of the given vibration or fundamental. This is in accordance with the mathematical treatment due to Fourier, who showed how to resolve any complicated periodic vibration into an infinite series of harmonic vibrations having the above frequencies, although in practical calculations a few terms are usually sufficient. Sometimes, as in the case of a closed organ pipe or an alternating electric current, only the odd harmonics can exist. When the possible higher frequencies are not simple multiples of the fundamental (as in vibrating rods, tuning fork, etc.), they are called "overtones" or "upper partials." It must not be supposed that all or any of the possible harmonics are actually present in a given case. That depends upon the nature of the vibrating substance and the way it is set in vibration; for instance, in strings it depends upon the point struck.

Harmonium (*Music*). *See* MUSICAL INSTRUMENTS—WIND (KEYED).

Harmony (*Music*). (1) An orderly succession of different combined sounds. (2) The study of chord building from "roots," and of connecting these chords in their different positions, having regard to key relationship.

Harness (*Silk Manufac.*) A collection of two or more HEDDLES (*q.v.*), healds, lames, or shafts used for making satin, twill, or other plain cloths.

—— (*Textile Manufac.*) In a Jacquard machine the group of cords carrying the MAILS (*q.v.*) through which the threads of warp pass. The depression of the cords is effected by each carrying a separate weight or lingo. These serve the same purpose as the heddles for tappet or dobby.

Harp (*Her.*) The national device of Ireland. It is borne in the Irish quarter of the Royal Arms of Great Britain.

—— (*Music*). *See* MUSICAL INSTRUMENTS, STRINGED (2).

—— *See* MUSICAL INSTRUMENTS—STRING (BY HAND).

Harp Pendant (*Gas Fitting*). A gas pendant in the form of a loop with the burner in the centre.

Harpsichord (*Music*). A precursor of the pianoforte, being a keyed instrument played by means of plectrums set in motion by the keys. A fine collection may be seen in the Victoria and Albert Museum, South Kensington.

Harpy (*Her.*) A fabulous heraldic creature represented as a vulture with a woman's head and neck.

Harrison's Gridiron Pendulum. *See* PENDULUMS.

Harrock Hill Stone. *See* BUILDING STONES.

Hart (*Her.*) A stag of full growth with branching horns. Borne as a charge or a crest. The female represented without horns is called a HIND.

Harvest Moon (*Astron.*) About the autumnal equinox and harvest time in England the moon, when full, possesses its minimum retardation, *i.e.* rises more nearly at the same time on successive nights than at other times of the year. It is then termed the harvest moon, for, rising at sunset, it affords aid to harvesters who have not ended their day's work.

Hat (*Her.*) A cardinal's hat is generally represented in the arms of an ecclesiastic who belongs to that princely order in the Church of Rome. It is red, with wide brim and pendent tassels.

Hatched Moulding (*Architect.*) A simple enriched moulding used in Norman work, generally as a string course. The moulding has a half-hexagonal projection; squares are marked out on the projecting faces, and the triangle below the diagonal of each square is slightly sunk.

Hatchet (*Carp., etc.*) A small axe.

—— (*Her.*) An ancient charge. William de Hursthelve in the thirteenth century blazoned azure, three hatchets argent.

Hatchet Stake (*Eng.*) A flat plate of metal with a sharp edge, fixed in a vertical position for bending sheet metal over.

Hatching (*Art*). A series of parallel lines, or several series crossing, employed in drawing and engraving to produce the effect of shading and so indicate the modelling of an object, tones, etc.

Hatchment (*Her.*) The achievement or armorial bearings of a person deceased. Sometimes hung outside the house where such person lived, and afterwards placed in the church near the family pew.

Hathor Headed Capital (*Architect.*) A form of capital used in Egyptian architecture. In this capital, a block of stone, carved on each face with a representation of the head of the Goddess Isis, and supporting a model of a temple, is introduced above a Campaniform capital. It is also known as the ISIS HEADED CAPITAL. *See* CAMPANIFORM CAPITAL, CLUSTERED LOTUS CAPITAL, LOTUS CAPITAL, *and* PALM CAPITAL.

Hat Leather (*Eng.*) A leather ring used as packing for hydraulic rams, etc. Its section is in the form of the letter L.

Hauberk (*Armour*). A long coat or tunic of mail used in the middle ages. Originally it was only intended to protect the neck and shoulders. *See* ARMOUR *and* MAIL.

Haulm (*Botany*). *See* CULM.

Haunch (*Build.*) The portion of an arch between the crown and springing. *See* ARCH.

Haunched Tenon (*Carp. and Join.*) A tenon cut back in its width to allow for wedging.

Hauptwerke (*Music*). The German name for Great Organ. *See* ORGAN.

Hauriant (*Her.*) "Paleways" or "in pale," and having the head in chief. Used to describe the position of a fish on a field, when it appears as if rising to the surface of the water for breathing. The converse is URIANT.

Hausmannite (*Min.*) Mangano-manganic oxide, Mn_3O_4. Manganese = 72·1, oxygen = 27·9 per cent. Occurs in small black tetragonal octahedra, which have a brown streak. From Thuringia, the Harz, United States, West Cumberland, etc.

Hautboy (*Music*). The French term for OBOE (*q.v.*)

Hawk (*Her.*) A bird of prey frequently used in heraldry. It is blazoned "belled," "jessed," and "varvelled." Varvelles are small rings attached to the jesses.

—— (*Plast.*) A square piece of board with a handle in the centre underneath. Used for holding a supply of plaster while it is being laid on a wall or ceiling.

Hawk Bells *and* **Jesses** (*Her.*) The small round bells attached to the legs of hawks. Hawks' jesses are the short leathern thongs fastened to each leg of a hawk and to which the leash held by the falconer is attached.

Hawser Pipe *or* **Hawse Pipe** (*Eng.*) (1) The hole through which a ship's cable runs out. (2) A similar opening through which the chain runs in some cranes.

Hawthorn. *See* WOODS.

Hay Band (*Foundry*). Roughly made ropes of hay wound round an iron bar, on which loam is to be placed to form a large CORE (*q.v.*) The hay serves to form a porous interior in the core, through which gases can escape when the hot metal comes in contact with the outside.

Hazel. *See* WOODS.

Hazel Nut Oil. A pale yellow inodorous oil obtained by expressing the fruit of *Corylus avellana.* The product is limited. It is used, when fresh, for cooking purposes, also for burning and for soap making.

Hazel Rods (*Eng.*) Thin rods of hazel are often used for the handles of smiths' tools (chisels, punches, etc.) which have to be struck by a hammer.

He (*Chem.*) The symbol for HELIUM (*q.v.*)

Head (*Build.*) (1) The end of a quoin stone. (2) The top end of a slate when fixed on a roof.

—— (*Carp. and Join.*) The top of a door frame; the top end of a shore, etc.

—— (*Cycles*). The socket or hollow tube through which the tube carrying the front forks runs. It has ball bearings at the top and bottom in most machines.

—— (*Eng.*) (1) The top of a tool or other object. (2) The depth or height of water in a vessel, which determines the pressure at any given point below the surface.

—— (*Typog. and Bind.*) The top part or margin of a page.

Head and Tail (*Bind.*) The head is the top of a book; the tail is the bottom.

Head Band (*Bind.*) The head band is the little ornamental accessory fixed to the head and tail of a volume inside the back, to give a finished appearance. Formerly they were worked in different coloured silks very carefully attached to the book itself, but now they can be bought ready made by the yard, and are glued on.

Header (*Build.*) A brick or stone with its end showing on the face of the wall, *i.e.* one with its longer axis at right angles to the plane of the wall.

Heading Course (*Build.*) A course of headers. *See* ENGLISH BOND.

Heading Joint (*Carp. and Join.*) Two floor boards joined end to end. *See* FLOORS.

Headington Stone. *See* BUILDING STONES.

Heading Tool (*Eng.*) A tool used for forming the heads of bolts, large nails, etc., when forged by hand.

Headline (*Typog.*) The heading (top line) on the page of a book.

Head Metal (*Foundry*). A kind of reservoir of metal connected with the interior of a mould by a gate (*q.v.*) or runner, or else opening directly into the mould itself. The scum, etc., rises into the head, leaving the casting sound; when the casting is removed the unsound metal forming the head is cut off.

Head Nailed (*Build.*) Slates fixed at the top end.

Headon Beds (*Geol.*) Rocks of fluvio-marine origin which were formed in the south of England during the Oligocene Period. They are best developed in the Isle of Wight and the maritime areas to the north-west of that district.

Head Room (*Carp. and Join.*) The vertical height of a landing trimmer above the stairs.

Headstock (*Eng.*) The part of a lathe which contains the MANDREL (*q.v.*)

—— (*Textile Manufac.*) The principal part of the self-actor or spinning mule. It consists of the mechanism for controlling the several motions, such as the delivery of the sliver, twisting, the drawing out and winding up of the carriage, and the winding up of the spun yarn on to the cop or bobbin.

Head Valve (*Eng.*) An upper valve of a pump; the lower valve is termed a FOOT VALVE.

Heald (*Textile Manufac.*) *See* HEDDLE.

Heart Cam (*Watches*). A heart-shaped piece used in split seconds work, chronographs, and other mechanisms where the parts are required to return to their original positions at the will of the operator. *See* SPLIT SECONDS CHRONOGRAPH.

Hearth (*Build.*) The cemented, tiled, or paved floor of a fireplace : the part of the floor which lies beneath and in front of the grate.

—— (*Eng.*) (1) The lower part or base of a furnace or the part containing the fire. (2) The part of a forge containing the fire.

Heart Wood (*Carp., etc.*) The wood forming the central part of the trunk of a tree.

Heat. A term used to denote the sensation of warmth, and also the physical cause of that sensation. From the latter point of view heat is now regarded as being a kind of molecular vibration or motion, and hence a form of energy.

—— (*Eng.*) The term is used in engineering and other trades in various senses, in addition to the correct scientific one. Thus it is applied to (1) the temperature at which an operation is carried out, *e.g.* WELDING HEAT; (2) the process of heating materials to such a temperature; (3) the amount of material dealt with at one time or in one single operation.

——, **Atomic** (*Chem.*) *See* ATOMIC HEAT.

——, **Conduction of** (*Phys.*) *See* CONDUCTIVITY, CONDUCTION OF HEAT, *etc.*

Heat Equator (*Meteorol.*) Owing to the great extent of land in the Northern Hemisphere the highest mean annual temperature of the parallels of latitude is found at latitude 10° N.

Heating Apparatus (*Eng.*) Radiating apparatus by which heat is distributed to warm a building by hot water, air, or steam. Occasionally electric heaters are employed; they have the advantage that heat can be given out at a point considerably removed from the source, without as much loss at intermediate points as occurs with the methods previously mentioned.

Heating of Bearings (*Eng.*) Bearings when not sufficiently lubricated become very hot; they then become very much worn, or the surfaces in contact may adhere, and a fracture may occur. In large installations of machinery it is often found advisable to keep one man entirely employed in looking after the bearings to prevent heating; this is usually done, for example, on a large steamship.

Heating of Buildings. *See under* SANITATION.

Heating Surface (*Eng.*) The area of a boiler, including flues and tubes, which is in contact with the fire or the hot gases.

Heat, Latent (*Phys.*) *See* LATENT HEAT.

——, **Mechanical Equivalent of** (*Phys.*) *See* MECHANICAL EQUIVALENT OF HEAT.

——, **Molecular** (*Phys.*) *See* MOLECULAR HEAT.

Heat of Combustion (*Chem.*) The amount of heat evolved, expressed in calories (*q.v.*), when the molecular weight, taken in grams, of any substance is completely burned. In the case of elements, that quantity is taken which will give one gram-molecule (*q.v.*) of the product. Thus in the case of acetic acid ($C_2H_4O_2$) the heat of combustion is the number of calories evolved when 60 grams (60 being the molecular weight) are completely burned to water and carbon dioxide. But in the case of carbon, whose molecular weight is unknown, the heat of combustion is the number of calories evolved when 12 grams are completely burnt to 44 grams (the molecular weight) of carbon dioxide. *See also* THERMOCHEMISTRY.

Heat of Formation (*Chem.*) The heat (expressed in calories) evolved or absorbed in the production of the gram molecular weight of a substance from its elements. *See also* THERMOCHEMISTRY.

Heat of Ionisation (*Phys.*) The internal energy of a substance in its neutral state is not necessarily the same as its energy when in the ionised state, and the difference may be positive or negative. This difference is known as the HEAT OF IONISATION.

Heat of Solution (*Phys.*) The total amount of heat which is either absorbed or set free by dissolving one gram of a substance in a given solvent.

Heat, Radiant. *See* RADIANT HEAT.

Heat Radiator (*Motor Cars*). A device by which the cooling of the cylinder of a motor cycle or of the condenser of a car is promoted. A series of flanges or "gills" are attached to the tubes of a condenser (or cast on the body of a cylinder); these become heated by conduction, and dissipate the heat into the atmosphere by radiation.

Heat, Specific. *See* SPECIFIC HEAT.

——, **Unit of.** The heat necessary to raise unit mass of water through unit rise of temperature (1°). The English engineer uses the pound and the degree Fahrenheit as the respective units: in scientific work it is usual to employ the CALORIE (*q.v.*)

Heaume (*Armour*). *See* HELM.

Heaves (*Geol.*) A miner's term for the lateral shift of a fault or lode which has been produced by the action of a fault of *later* date. An allied phenomenon of considerable importance in connection with metalliferous veins is that in which a newer fault or lode traversing an older one has been deflected by the older line of weakness. Many dykes have been TRAILED (as this deflection is termed) by this cause.

Heavy Oil (*Chem.*) That fraction of coal tar which distils between 230° and 270° C. It is used under the name of CREOSOTE. *See* GAS MANUFACTURE (COAL TAR DISTILLATION).

Heavy Spar (*Min.*) A synonym for BARYTES (*q.v.*)

Heck (*Cotton Manufac.*) A framework carrying needles by which a lease is formed when "warping."

Hecto-. A prefix used in the metric system to denote a multiple of one hundred times the measure to which the prefix is applied; *i.e.* hectolitre, one hundred litres. *See* WEIGHTS AND MEASURES.

Heddle (*Textile Manufac.*) The Scotch term for HEALD-SHAFT. Heddles consist of upper and lower wooden shafts or laths fastened together by HEALD CORDS, which contain in the centre a MAIL or EYE, through which the threads of warp are passed separately. Each pair of laths or staves are under separate control by the TAPPET or DOBBY, and thus the warp threads are raised or depressed to interlace with the weft as it is shot across in the loom.

——, **Heald, Lame,** *or* **Shaft** (*Silk Manufac.*) Two flat sticks called VERGEES, placed parallel about 15 in. apart, connected by a series of fine cotton threads, each having in the middle a loop or eye to receive the warp thread. In the "Grob" system, lengths of flattened steel wire perforated in the centre for the eye replace the cotton thread.

Heddon Stone. *See* BUILDING STONES.

Heel Ball. A composition of carnauba wax, resin, blacking, and paraffin wax, used for rubbing on the heels and sides of the soles of boots to give a finish.

Heel Strap (*Carp. and Join.*) The iron band securing the foot of the principal rafter to the tie-beam.

Heel Tool (*Eng.*) An old form of hand-turning tool used in taking a heavy cut. It had a bend or heel near the cutting end which rested on the top of the T-rest. A similar cut is usually taken by a slide rest tool in modern lathes.

Height of Barometer. The length of a vertical column of mercury whose pressure is equal to that of the atmosphere. *See* BAROMETER.

Heliacal Rising *or* **Setting** (*Astron.*) The rising or setting of a celestial body just before sunrise or just after sunset.

Helianthin (*Chem.*) METHYL ORANGE (*q.v.*)

Helianthus (*Botany*). A well known genus of the order *Compositæ*. *H. annuus* is the sunflower, whose seeds yield a useful oil; *H. tuberosus* is the Jerusalem artichoke.

Helical Gear (*Eng.*) Gear wheels with teeth set at an angle with the axis of the wheel.

Helical Spring. A spring produced by winding a steel strip or wire on the surface of a cylinder; often erroneously called a "spiral spring." *Cf.* HELIX *and* SPIRAL.

Helical Tube (*Cycles*). A tube made of a long strip of steel wound on a cylindrical roller in the form of a helix (or so-called "spiral") and brazed at the edges into a continuous tube.

Heliograph. An instrument for signalling through considerable distances by means of a beam of sunlight. It consists of a small mirror mounted upon a suitable stand, and arranged so that the sun's light may be reflected to the distant station, where it can be observed as a luminous point by means of a telescope. The signals are then produced by a series of flashes.

—— (*Astron.*) An instrument, generally equatorially mounted, for photographing the sun.

Heliometer (*Astron.*) An equatorially mounted telescope, the object glass of which is diametrically divided into two parts, which are capable of sliding past each other.

Helioscope (*Astron.*) A special form of solar eyepiece used when observing the sun, in order to protect the eye from the intense brilliancy and heat of the rays.

Heliostat. An instrument for obtaining a beam of sunlight in an invariable direction for experimental purposes, etc. It consists essentially of a mirror provided with a clockwork motion which enables it to follow the apparent motion of the sun.

Heliotrope (*Min.*) A semi-translucent green variety of CHALCEDONY, spotted with red.

Helium (*Chem.*), He. Atomic weight, 4. A colourless gas; has not been liquefied; least soluble of all gases (100 vols. water dissolve ·73 vols. He). It has a monatomic molecule. Cannot be made to enter into chemical union with any other element or compound. Occurs in the sun, in the Earth's atmosphere to a small extent, and in certain rare minerals which contain uranium, thorium, yttrium. The minerals richest in helium are clèveite, uraninite, and bröggerite. From these it is obtained by heating under greatly reduced pressure. Other gases evolved at the same time are removed by suitable treatment: thus hydrogen is made to unite with oxygen to form water, and nitrogen is made to combine with heated magnesium. The spectrum of helium contains two lines exceedingly near together in the yellow; it was from the presence of this double line in the solar spectrum that this element was discovered in the sun thirty years before Professor Ramsay discovered it in the rare minerals referred to above. Helium has been used as a thermometric substance in measuring the very low temperatures at which hydrogen boils and solidifies. It is estimated that the boiling point of liquid helium will be about 5° above the absolute zero. *See also* RADIUM.

Helium Stars (*Astron.*) Stars the spectra of which show prominently the lines of the gas helium.

Helix. The curve produced when a line is wound regularly round the surface of a cylinder (or cone) so as to lie in that surface. The thread of a screw and a spring of the elongated form are examples.

Helm *or* **Heaume** (*Armour*). A helmet of great size and strength, used in the twelfth and thirteenth centuries. It was generally worn over a smaller head covering, *e.g.* the bascinet (*q.v.*), and reached down to the shoulders. *See also* ARMOUR.

Helmet (*Armour*). A general term for the defensive covering for the head. It varied in form during successive periods from the Chapelle-de-fer (*q.v.*) to the helmet worn at joust and in battle from the fourteenth to the sixteenth centuries. *See* HEAUME *and* ARMOUR.

—— *or* **Helm** (*Her.*) Used as an accessory above a shield of arms. It has various forms according to the period. It is placed above the shield resting upon the "chief." Commoners, knights, and baronets have their crests placed upon their helms, sustained by wreath, cap, or crest coronet. Peers and princes place their coronets upon the helm and their crest above the coronet. The helm of the sovereign and princes of the Blood Royal is of gold, and placed "affrontée," guarded with six bars; that of nobles of silver, placed in profile, with five bars; that of baronets and knights is of steel, "affrontée," vizor raised and without bars. Esquires and gentlemen, vizor is closed and placed in profile. Helmets are also borne as charges upon a field.

Helve. The handle or haft of a hammer.

Helve Hammer (*Eng.*) An obsolete form of mechanically worked hammer.

Helvetia Leather. *See* CROWN LEATHER.

Hematite (*Min.*) A synonym for HÆMATITE (*q.v.*)

Hemicrystalline Rocks (*Geol.*) These may be typified by basalt, a rock of eruptive origin, in which some of the constituent minerals had crystallised from solution before the fluid matrix began to consolidate. Hence these minerals are enclosed within a stony or lithoidal matrix which is usually devoid of crystalline structure. All lavas are necessarily hemicrystalline in structure.

Hemihedral Forms (*Min.*) Crystal forms in which alternate faces or alternate groups of faces of the holohedral forms (*q.v.*) are suppressed.

Hemimorphism (*Min.*) A condition where a doubly terminated crystal shows dissimilarity of forms at the opposite ends. It is well seen in Hemimorphite, in Greenockite, and in Epsom Salts.

Hemimorphite (*Min.*) Hydrous silicate of zinc, $ZnSiO_3 . 2H_2O$. Silica = 25·1, oxide of zinc = 67·4, water = 7·5 per cent. Orthorhombic, hemimorphic (*q.v.*); also massive. White, pale yellow to green and blue. Also called Smithsonite, and, by some American writers, Calamine. From Somerset, Derbyshire, Cumberland, Silesia, Hungary, the United States, etc.

Hemisphere. The half of a sphere cut off by a plane passing through the centre.

Hemp (*Botany*). The macerated bast fibres of *Cannabis sativa* (order, *Moraceæ*) yield a valuable material for ropes, etc. The seeds, oil, and a resin are also used.

Hempseed Oil. This is obtained by expressing the seed of *Cannabis sativa*. It is a greenish yellow when freshly pressed, but the greenish tint disappears when refined. It may be used for the same purposes as olive oil, as a burning oil, and for soap making. It is often employed to adulterate linseed oil, the effect of the addition being to retard the drying. The specific gravity at 15° C. is 0·925 to 0·930.

Henry's Law. (*Chem.*) The amount of a gas (by weight) which dissolves in a liquid varies directly with the pressure on the gas when the temperature is constant. This law only holds for the less soluble gases.

Heraldry. In the modern sense heraldry is the art of blazoning or describing armorial bearings. Formerly it dealt also with genealogy and precedence. Although probably of ancient origin, heraldry only assumed definite individual and hereditary character about the middle of the twelfth century, this being largely due to the increasing necessity for knights in full armour to bear some distinctive device for the purpose of identification. Between the twelfth and fifteenth centuries rules had been formulated for the blazoning of arms, the arrangement of devices, colours, etc.; and the science had become sufficiently systematised to warrant the establishment of an authority to regulate matters pertaining to the bearing of arms and the claims of descent. The Heralds College was accordingly constituted about 1425 by Edward III.

HERALDIC COLOURS OR TINCTURES.—There are a certain number of "tinctures" used in heraldry, both for the field or groundwork of a shield, and also for the various charges that may be placed upon it. They are of three kinds: metals, colours, and furs. Only two METALS are employed, *viz.* gold and silver, called respectively *or* and *argent*, the former represented in engraving by small dots, and the latter by a plain white surface. There are five COLOURS most commonly employed, besides one or two others rarely used:

1. Azure is *blue*, and represented by horizontal lines.
2. Gules is *red*, and represented by perpendicular lines.
3. Sable is *black*, and represented by horizontal and perpendicular lines crossing.
4. Vert is *green*, and represented by diagonal lines drawn from dexter chief to sinister base of the shield.
5. Purpure is *purple*, and represented by diagonal lines drawn from sinister chief to dexter base.
6. Tenné is *orange*, and represented by diagonal lines as vert, crossed by horizontal.
7. Sanguine is *blood colour* or *dark red*, and represented by diagonal lines as purpure, crossed by other diagonal lines as vert.

The FURS are eight in number, *viz.*

1. Ermine: A field "argent," powdered with spots "sable."
2. Ermines: The reverse of the former.
3. Erminois: A field "or" powdered "sable."
4. Pean: The reverse of the former.
5. Vair: The field covered with little shield shaped figures, argent and azure alternately.
6. Counter vair: When the small shields are arranged point to point and base to base.
7. Potent: The field covered with small potents or crutches, tincture like vair.
8. Counter potent: The potents placed point to point and base to base.

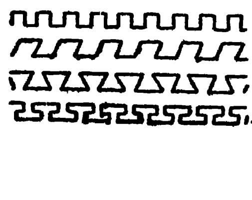
Metal should never be placed upon metal in charges, nor colour upon colour. Figures borne on a shield in their natural colours are described as "proper."

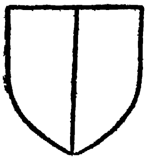
PARTITION LINES.—There are in general use the following methods of dividing a shield, *viz.*

1. By a perpendicular line, called *party per pale* or *impaled*.
2. A horizontal line across the middle, called *party per fesse*.
3. A perpendicular and horizontal line crossing, called *party per cross* or *quarterly*.
4. A diagonal line, called *party per bend*.
5. A diagonal both dexter and sinister, called *party per saltire*.
6. Two lines rising from opposite sides of the base and meeting in form of an acute angle at the fesse point, called *party per chevron*.
7. The latter with a perpendicular line to point of intersection, called *grafted* or *party per pale and chevron*.

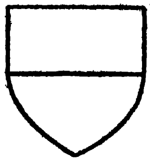
The dividing lines are either straight or assume the following ornamental forms:

Engrailed .
Invected .
Wavy or Undée
Nebulée .
Indented
Dancetté
Embattled
Ragulée .
Dovetail .
Potentée .

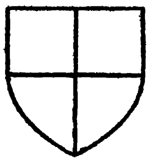




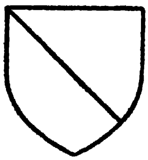
PER PALE.



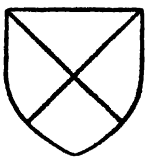
PER FESSE.



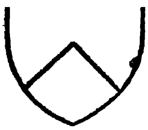
PER CROSS OR QUARTERLY.



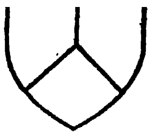
PER BEND.



PER SALTIRE.



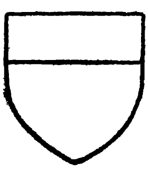
PER CHEVRON.



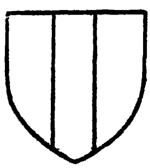
PER PALE AND CHEVRON.

CHARGES.—Whatever device is placed upon a shield it is called in heraldry a "charge." Charges are divided into three classes, *viz.* Honourable ordinaries, subordinaries, and common charges. They are called ordinaries from being used most ordinarily.

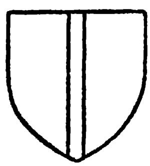
ORDINARIES.—The following are the honourable ordinaries and their diminutives:



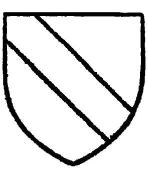
THE CHIEF.



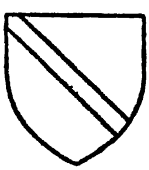
THE PALE.



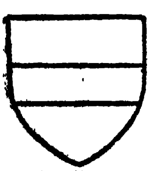
THE PALLET.



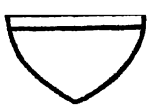
THE BEND.



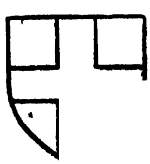
THE BENDLET.



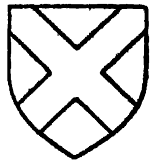
THE FESSE.



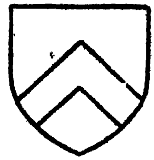
THE BAR.



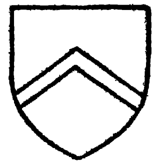
THE CROSS.



THE SALTIRE.

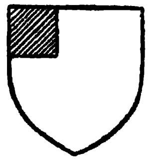


THE CHEVRON.

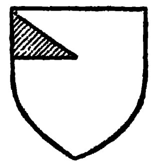


THE CHEVRONEL.

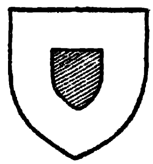
SUBORDINARIES.—There are some fifteen subordinaries; authorities differ as to the exact number. These, combined with ordinaries, and by means of partition lines and various charges, can be made to afford an almost infinite variety of coats of arms:



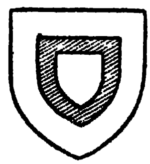
CANTON.



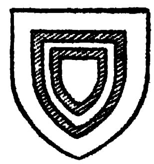
GYRON.



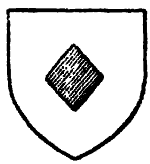
INESCUTCHEON.



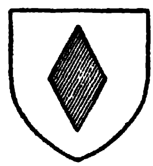
ORLE.



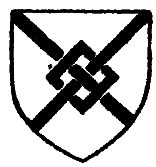
TRESSURE.



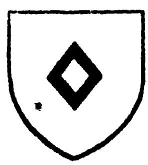
LOZENGE.



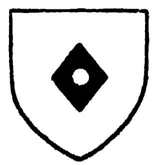
FUSIL.



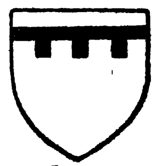
FRETTE.



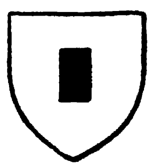
MASCLE.



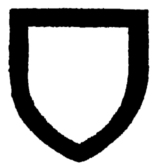
RUSTRE.



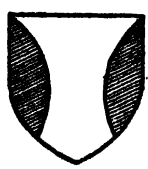
LABEL.



BILLET.



BORDURE.



FLANCHES.

FLASQUES OR VOIDERS.

See also ARMORIAL BEARINGS, COAT ARMOUR, *and* CROSS.

Herma, *pl.* **Hermæ** (*Archæol., Art*). A kind of statue consisting of a head or bust (generally that of the god Hermes) set on a quadrangular pillar. Used by the Greeks and Romans as boundary marks, decorative pillars, etc.

Herring (*Zool.*) *Clupea harengis* (family, *Clupeidæ*). A well known food fish found in the North Atlantic. The young of the herring form a greater part of whitebait.

Herring Bone (*Architect., etc.*) A term applied to stones, bricks, or other small component parts of a structure, etc., set diagonally; the members of adjoining rows usually slope in opposite directions.

Herringbone Bond (*Build.*) A cross bond in the interior of thick walls.

Herringbone Strutting (*Carp. and Join.*) Cross strutting between floor joists.

Heterocyclic Compounds (*Chem.*) Ring compounds containing more than one element in the ring; *e.g.*

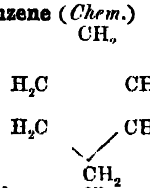
Pyridine,  Thiophene, 
Furfurane,  Pyrrole, 
Glyoxaline, 
See also CLOSED CHAIN COMPOUNDS.

Heulandite (*Min.*) Hydrous silicate of aluminium and iron, $Al_2O_3 . 3SiO_2 + CaO . 3SiO_2 + 5 H_2O$. Monosymmetric. White, brownish to rich red. From Stirlingshire, Antrim, Iceland, India, etc.

Hevea (*Botany*). A genus of *Euphorbiaceæ* belonging to tropical America. It is the source of Para rubber.

Hewett's Mercury Vapour Lamp. *See* MERCURY VAPOUR LAMP.

Hexahydrobenzene (*Chem.*)



A liquid with benzene-like smell and a boiling point almost the same as benzene (81°). It occurs in Russian petroleum. Can be prepared by reducing benzene with hydriodic acid at a high temperature. *See also* NAPHTHENES.

Hexamethylene (*Chem.*) HEXAHYDROBENZENE (*q.v.*)

Hexastyle (*Architect.*) A term used to denote that form of temple which has six columns in the front row. *See* OCTASTYLE, TETRASTYLE, DISTYLE, *and* DECASTYLE.

Hexoses (*Chem.*) *See* SUGARS.

H Girder (*Eng.*) A wrought iron or steel girder whose cross section has somewhat the form of the letter H, with the horizontal stroke long in proportion to the vertical ones. Also termed an I girder.

Hickory. *See* WOODS.

Hides (*Zool.*) The skins of the horse, deer, sheep, pig, dog, etc., used in the manufacture of leather. The term is applied more particularly to the skins of large beasts that may be tanned into leather.

Hieroglyphics, Hieroglyphs (*Archæol.*) The characters used in writing by the ancient Egyptians (and other ancient races). They consisted of figures of animals and objects symbolising some word, syllable, or sound; picture writing.

High (*Typog.*) A term applied to type or blocks which stand out in front of the rest of the type in the forme; *e.g.* new type stands higher than worn type.

High Flash Point. Oil whose vapour is only ignited at a high temperature. *See* FLASHING POINT.

Highgate Resin (*Min.*) *See* COPALINE.

High Pressure Cylinder (*Eng.*) The cylinder of a compound engine in which the steam is first expanded before passing on to the remaining cylinder or cylinders, in which the expansion is completed.

High Relief (*Sculp.*) *See* ALTO RELIEVO.

High Speed (*Eng.*) A purely relative term; applied to the linear velocity of ships, vehicles, etc., and to the rate of rotation of various motors and engines. In steam engines of the ordinary reciprocating type 400 revolutions per minute is a high speed; a small gas or petrol engine may make 1,200 to 2,000, a Parsons' steam turbine (*q.v.*) 3,000, and a small Laval turbine as many as 30,000 per minute.

High Speed Bearings (*Eng.*) Bearings whose length is four or five times their diameter are commonly used for very rapidly rotating shafts, and in many cases (especially in dynamos) the whole bearing has some slight freedom of rotation about axes at right angles to the shaft; this allows for slight errors in the alignment, or a slight amount of "give" or deformation of the shaft itself which might otherwise have serious results at high speeds.

High Warp. Tapestry in which the warp (*q.v.*) takes a vertical position, *e.g.* Gobelins tapestry. Supposed to be superior to low warp tapestry, which is manufactured with the warp in a horizontal position.

Hills, Origin of (*Geol.*) In most cases the elevated tracts known in general terms as "hills" are due either to the local piling up of materials, such as sand deposited by sea spray or drifted by the wind, or else are remnants of a mass of rock which formerly had a greater extent, but which was locally removed by some natural agent, such as running water. Hampstead and Finchley, for example, were once continuous high ground with Shooters Hill.

Himation (*Archæol.*) An outer garment worn by the ancient Greeks. It consisted of an oblong piece of cloth which covered the left shoulder, and was generally fastened over the right shoulder, leaving the right arm free.

Hip Girdle (*Zool.*) A group of bones (PELVIC GIRDLE) which give attachment to the hind limbs. The girdle is articulated to the vertebral column, and consists of the three bones, ilium, ischium, and pubis.

Hipped Roof (*Build.*) A form of roof in which the ends slope as well as the sides, there is therefore no gable.

Hippuric Acid (*Chem.*) (Benzoylglycocoll),

$$\begin{array}{l} CH_2NH\,.\,COC_6H_5 \\ | \\ COOH \end{array}$$

A white crystalline solid; melts at 187°; sparingly soluble in cold water (1 in 600); easily soluble in hot water and in alcohol. It occurs in the urine of herbiverous animals, especially of horses (hence the name); to a slight extent in human urine. When horse's urine is concentrated and hydrochloric acid added, hippuric acid separates out. It may be obtained synthetically by the action of benzoyl chloride on glycocoll in presence of caustic soda solution. On boiling the acid with strong hydrochloric acid it yields benzoic acid and glycocoll hydrochloride.

Hippurite Limestone (*Geol.*) A section of the Upper Cretaceous Rocks, mainly contemporaneous with the British Chalk. It was formed in a different zoological province from the normal Chalk, and contains the remains of a somewhat anomalous group of mollusca, whose affinities may be with the modern *Chama.* It occurs in force in the north-western part of the Mediterranean basin.

Hip Rafter (*Build.*) The angle rafter of a hipped roof. *See* ROOFS.

Hitch. (1) A check or stoppage of any kind; in particular, the stopping of a cutting tool through digging into the material. (2) In a rope, a loop, turn, or knot of a particular kind.

Hoar Frost (*Meteorol.*) When the air contains moisture and the temperature sinks below the freezing point, the particles of moisture become frozen and are deposited on leaves, trees, etc., in the form of hoar frost.

Hod (*Build.*) A three sided receptacle used for carrying bricks, mortar, or stones. Attached to it underneath is a straight handle about 4 ft. long, by which it is supported while being filled, and by means of which the hodman balances it on his shoulder when carrying the material to the workmen.

Hodograph. If lines be drawn from a fixed point, representing in magnitude and direction the velocity at successive instants of a moving body, the extremities of the lines lie on a curve termed the HODOGRAPH of the motion of the body.

Hofmann's Apparatus. *See* VAPOUR DENSITY.

Hofmann's Violet (*Chem.*) Is triethylrosaniline, a dye. Not used now. *See* ROSANILINE.

Hog Fleece, Hog Wool (*Woollen Manufac.*) The first shorn fleece of a young sheep.

Hogging (*Eng.*) The curvature of a girder, ship, or other structure, so that it is convex on the upper side; *i.e.* the central portion becomes raised relatively to the ends. *Cf.* SAGGING.

Hoist (*Eng.*) Lifting mechanism. The term is applied to a great many machines; a lift or elevator.

Holding Up (*Eng.*) Pressing a hammer, etc., against one end of a rivet while the "closing" or formation of the head is effected. The hammer is held by its handle, and the head springs away from the rivet after its inertia has been overcome by the blow of the riveter's hammer.

Holding Weft (*Textiles*). *See* WEFT.

Hollander (*Paper Manufac.*) A type of beating engine used for beating up rag pulp.

Hollands (*Linen Manufac.*) These are light plain-texture linens finished in the brown state, or dyed black, slate, etc., and highly glazed. Generally used for linings

Hollington Stone. *See* BUILDING STONES.

Hollow Column (*Eng.*) A vertical column containing a given weight of metal is much stronger if hollow than if made solid, owing to the metal being farther from the axis. *See* BEAM. Many large frames, baseplates, and other structures are made hollow for this reason.

Hollow Mandrel Lathe (*Eng.*) For small repetition work, where a number of similar objects (*e.g.* screws, etc.) are formed from a rod of metal, it is very convenient to have a lathe with a hollow mandrel. The rod of metal runs right through this mandrel, and one end projects beyond the chuck for a sufficient distance; as each object is finished it is cut off, and a fresh length of rod brought into place without loss of time in re-chucking. A hollow mandrel is often used in conjunction with a capstan head on the slide rest, which is capable of holding a variety of tools.

Hollow Roll (*Plumb.*) A lead ROLL (*q.v.*) made by bending over the edges of sheet lead, and so forming a tube.

Hollows (*Carp.*) Planes used for forming convex surfaces; the corresponding planes for forming concave surfaces are known as ROUNDS. A set of hollows and rounds used always to form part of a joiner's outfit; with them he could cut any beads or mouldings or make his own beading planes.

—— (*Patternmaking and Moulding*). The curved surface connecting two flat surfaces meeting at an interior angle; the curve adds to the strength of the casting, which would otherwise be very liable to fracture at the angle, owing to the irregular arrangement of the crystalline structure at this point.

Hollow Walls (*Hygiene*). According to a model byelaw issued by the Local Government Board as to new buildings, if the ground is to be in contact with a wall above the level of the floor of the lowest story, that wall must be made double, with a cavity $2\frac{1}{2}$ in. wide extending from the base of the wall to 6 in. above the surface of the adjoining ground; and damp proof courses (*q.v.*) must be inserted both at the base of the wall and at the level of the top of the cavity.

Hollow Ware. *See* GLASS MANUFACTURE.

Hollow Ware Presser (*Pot.*) A hollow ware presser, as distinguished from a "flat ware" presser, is a potter who makes bowls, vegetable dishes, soup tureens, and similar hollow articles which are made by the "pressing" process.

Holly. *See* WOODS.

Holmes's Signal. A tin canister containing calcium phosphide and attached to a float. To the bottom of the tin a tube is fastened, and the end is perforated so as to admit water, when the signal is to be used; at the top of the tin is a cone, the apex of which is cut off also before use. When thrown into the sea, water entering below generates spontaneously inflammable phosphoretted hydrogen, which escapes above and burns with a brilliant flame. *See* PHOSPHORETTED HYDROGEN.

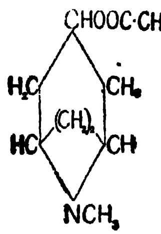
Holocrystalline Structure (*Geol.*) This occurs chiefly in eruptive rocks which have consolidated slowly and under pressure. It is confined to rocks of

either plutonic (deep seated) origin, or trappean rocks, such as dyke sand sills, which have been intruded at a lesser depth. The whole of the constituents have become crystalline; or, in other words, no trace of any ground mass is left. Granite or dolerite may be taken as typical examples. No lava is holocrystalline.

Holohedral Forms (*Min.*) Crystal forms which show the complete development of faces, *i.e.* the complete symmetry possible with a particular form.

Holtz Machine (*Elect.*) One of the first induction electrical machines of modern type; devised about 1865. It consists essentially of a fixed glass plate carrying two paper inductors and a rotating plate. The paper inductors, charged respectively + and −, act upon the rotating plate, and the repelled induced charges are received by collecting combs and led to the main terminals, where they form the working discharge. The attracted induced charges are made use of to maintain the polarity of the paper inductors, for which purpose two sector shaped windows are cut in the fixed plate, through which a tongue of the paper projects to touch the rotating disc. This type of machine requires an initial charge, and stops working when the main terminals are separated beyond the sparking distance. It is also much affected by atmospheric conditions.

Homatropine (*Chem.*)



The mandelic acid ester of tropin (*q.v.*) It is used in the form of its hydrobromide, a white crystalline solid, for dilating the pupil of the eye. Its effect does not last so long and it is not so poisonous as atropine.

Homberg's Phosphorus (*Chem.*) Fused calcium chloride. This salt, when exposed to the sun's rays for a time and then taken into a dark room, becomes phosphorescent.

Homberg's Pyrophorus (*Chem.*) A mixture of finely divided carbon, potassium sulphide, and aluminium sulphate obtained by heating alum and charcoal to redness out of contact with air. It becomes red hot on exposure to air.

Home Work (*Hygiene*). Sec. 107 of the Factory and Workshops Act, 1901, requires that lists of "outworkers" in such classes of work as may from time to time be specified by Special Order of the Secretary of State shall be kept by occupiers of factories and workshops and contractors employed by them, and shall be forwarded twice yearly, in February and August, to the District Council in which the factory or workshop is situate. Every Council shall furnish particulars as to "outworkers" employed outside their district to the Council of the district in which such workers are employed. By Sec. 108 the District Council is empowered to give notice to employers prohibiting work to be done on unwholesome premises. This section applies only to persons employed in such classes of work as the Secretary of State may specify by Special Order. Sec. 109 prohibits the making, cleansing, or repairing of wearing apparel where there is scarlet fever or smallpox. Sec. 110 prohibits home work in a house any inmate of which is suffering from a notifiable infectious disease. The work to which this section applies is the making, cleaning, washing, altering, ornamenting, finishing, and repairing of wearing apparel, and any work incidental thereto, and such other classes of work as may be specified by Special Order.

Homocentric (*Photo.*) A term employed in optics to signify that a lens is corrected for radial and tangential astigmatism of oblique pencils of light by the merging of the two focal lines into a single focal point. It is the aim of all modern anastigmatic lenses to accomplish this, in order to prevent the blurring of the image formed on the margins of the focussing screen from this defect of astigmatism.

Homogeneous. Of uniform structure throughout. In engineering, etc., a perfectly homogeneous casting or forging is much stronger than one whose internal structure is not uniform.

Homologous Series (*Chem.*) A series of organic compounds the members of which differ from each other by a multiple of CH_2. The hydrocarbons of the paraffin series form an example. Another example is the following:

$COOH\,.\,COOH$	Oxalic acid.
$COOH\,.\,CH_2\,.\,COOH$	Malonic acid.
$COOH\,.\,CH_2\,.\,CH_2\,.\,COOH$	Succinic acid.
$COOH\,.\,CH_2\,.\,CH_2\,.\,CH_2\,.\,COOH$	Glutaric acid.

Hone. A smooth grained stone used for giving a fine edge to sharp cutting tools. Hones are generally some variety of slate or similar rock.

Honey (*Botany*). The saccharine fluid secreted by glands (nectarines) in flowers. It undergoes certain changes within the stomach of the bee, and is afterwards transferred to the cells of the honeycomb.

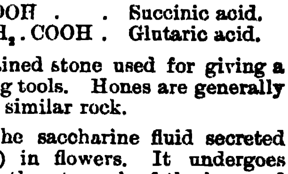
Honeycomb (*Textile Manufac.*) The term applied both to weave and fabric. It is a weave in which there is strong contrast of fast and loose interlacings, giving to the fabric a rough and honeycombed character.

Honeycombing (*Eng.*) Corrosion of boilers in the form of numerous pits or holes on the internal surface.

Honourable Ordinaries (*Her.*) The nine principal ordinaries. *See* HERALDRY *and* ORDINARIES.

Hood (*Eng.*) The funnel-like cover over a forge which leads the smoke, etc., into the chimney.

Hood Mould (*Architect.*) A projecting moulding used in Gothic work over the heads of doors and windows, following the curve of the arch. When used externally it serves the purpose of throwing off the rain; but it is also used, solely for ornament, in internal work. It is also known as a DRIPSTONE, WEATHER MOULDING, and when square in elevation as a LABEL.



HOOD MOULD.

Hooked Joint (*Carp. and Join.*) A joint in the form of a hook. Used on the meeting styles of casements and airtight cases.

Hooke's Joint (*Eng.*) A joint used to connect two lengths of rotating shafting which are not in the same straight line. Each length terminates in a horseshoe shaped fork; the ends of each fork are connected to the ends of one arm of an equal armed cross by swivel joints: if the shafts are in line, the plane of the cross is at right angles to the line of the shafts; when the shafts are not in the same straight line, the plane of the cross is inclined to either one or both shafts.

Hooke's Law (*Phys.*) Hooke discovered that if an "elastic" substance be strained or loaded in any way, then, within certain limits of load varying with the nature of the substance used, the strains produced are proportional to the loads. The law is now usually expressed in the form $\frac{\text{Stress}}{\text{Strain}} = \text{Constant}$, and this constant is known as the "Elasticity" of the substance.

Hook Up, Hook Down (*Typog.*) The end of a line which is either bracketed in the line above or that below.

Hoop Iron (*Eng.*) Thin bands of wrought iron of thickness from 20 up to 12 B.W.C. *See* WIRE GAUGES. Used for securing barrels, etc.

Hoop Iron Bond. Thin strips of iron built into walls to tie the materials together.

Hooter. A powerful steam whistle giving a deep note, used as a signal. A siren.

Hope's Experiment (*Phys.*) A well known experiment to demonstrate the existence of anomalous expansion in water near its freezing point, and also to roughly ascertain the temperature of maximum density. The apparatus consists of a tall, rather narrow cylinder containing water at the ordinary temperature, and having holes at the side for the insertion of two thermometers near the top and bottom respectively, while around the middle of the cylinder is an annular receptacle for a freezing mixture. At first the temperature of the lower thermometer falls rapidly, while the upper one is not much affected. This goes on until the lower one reaches about 4° C., then it remains stationary, and the upper one begins to fall, until at length ice may form at the top. Evidently the water becomes denser during cooling until 4° C. is reached, and then becomes less dense with further cooling.

Hopper. A funnel formed in the shape of an inverted cone or pyramid, used for feeding coal or other material in fragments into a furnace, etc.

—— (*Build.*) (1) The head of a rain water pipe. (2) A certain form of closet pan.

Hopper Feed (*Woollen Manufac.*) An automatic mechanism in which the wool is put, and then conveyed automatically on to the feed sheet of the carder. This feed is also applied to other machines, such as the scribbler.

Hops (*Botany*). *Humulus lupulus* (order, *Moraceæ*). The plant is much cultivated in the south-east of England for brewing purposes. *See* BEER.

Horizon (*Astron.*) The intersection of the celestial sphere by a plane through the eye of the observer, parallel to the surface of a liquid at rest (*i.e.* a horizontal plane).

——, **Artificial** (*Astron.*) A level reflecting surface (*e.g.* a dish full of mercury), used in finding the altitude of a star when the natural horizon is hidden.

Horizon, Geological. A term which has reference to the chronological position of any rocks which have been formed at the same period of the Earth's history, quite irrespective of their mode of origin or lithological character. Thus the desert-formed sandstones and marls of the English Trias are on the same geological horizon (or were formed contemporaneously with) certain thick beds of dolomite of marine origin in Tyrol. In like manner certain volcanic rocks in Scotland are on the same geological horizon as the limestones of Dovedale.

Horizontal Engine. Any engine whose cylinders are horizontal, but usually applied only to stationary engines.

Horizontal Force, Magnetic. The horizontal component of the magnetic force of the earth at a given place, important because it is the effective value acting upon a compass needle. Its value in London at the present time is about ·18 C.G.S. units, *i.e.* ·18 dynes per unit pole.

Horn (*Music*). *See* MUSICAL INSTRUMENTS, WIND (BRASS).

——. *See* WASTE PRODUCTS.

Hornbeam. *See* WOODS.

Hornblende (*Min.*) Silicate of iron, magnesium, aluminium, and calcium. It is one of the meta-silicates, and is now considered an aluminious variety of the species AMPHIBOLE (*q.v.*) It occurs in black monosymmetric crystals, and is an important rock forming mineral, which occurs in many gneisses, pegmatites, and eruptive rocks. It occurs along with Biotite in most of the Scottish granites and diorites, and is a common mineral in many of the andesites, porphyrites, and trachytes.

Horn Centres. Discs of horn or celluloid placed on drawings to form a point of rotation for compasses when many circles have to be drawn from the same centre; the puncturing of the paper is thus prevented and the centre maintained in its proper fixed position. The disc is usually provided with fine projecting points, which keep it in place.

Horn Lead (*Min.*) A synonym for PHOSGENITE (*q.v.*)

Horns (*Carp. and Join.*) The portion of the styles of framing projecting beyond the rails.

—— (*Eng.*) (1) In general any projecting part or point. (2) The tips or corners of the pole pieces of the field magnets of a dynamo or electric motor.

—— (*Zool.*) *See* WASTE PRODUCTS.

Horn Silver (*Min.*) Silver chloride, AgCl. Silver = 75·3, chlorine = 24·7 per cent. Cubic. More often in massive forms with a characteristic ivory lustre. It occurs, rarely, in Cornwall and in the Harz Mountain mines, but is sufficiently plentiful in South America to be a valuable ore of silver. Also in New South Wales.

Horology. *See* WATCHMAKING.

Horse (*Plast.*) The wood backing of a zinc mould, used by plasterers for running mouldings.

—— (*Plumb.*) A wooden finial, etc., forming a core which is to be covered with lead.

Horse-Brey *or* **Barnacles** (*Her.*) A kind of curb used in breaking in horses; it presses on the animal's nose. Used occasionally as a "charge."

Horse-Chestnut. *See* WOODS.

Horse-Chestnut Oil. Made from the fruit of the horse-chestnut tree. The colour of the oil is greenish brown. It may be used for burning and soap making, and is said to possess valuable medicinal qualities when used externally for gout, rheumatism, neuralgia, etc.

Horse Dung (*Foundry*). Used to give porosity to loam, from which large cores are made.

Horse Fat. Varies in colour from very light to dark yellow, according to the part of the animal it is taken from. It is used as an adulterant for lard and in soap making. The sp. gr. at 15° C. is 0·9180.

Horseflesh (*Foods*). By the Sale of Horseflesh, etc., Regulation Act, 1889, the flesh of horses, asses, and mules must not be sold or kept for sale for human food except in a shop or stall over or upon which is placed, in conspicuous and legible characters 4 in. long, an announcement that horseflesh is sold there. The following characteristics of horseflesh serve to distinguish it from beef: (*a*) The muscle fibre is much coarser. (*b*) It is darker red in colour, often has a brownish tint. (*c*) After being kept a day or two it develops a peculiar odour, and has a velvety feel to the fingers. (*d*) The fat is a deep yellow, and has a distinct odour from the first. (*e*) The ridges and tuberosities on the bones are bigger than on the bones of oxen. (*f*) Horseflesh is rich in glycogen; beef contains scarcely any. *See* FOODS.

Horse Gear. The device used for yoking horses to machinery. *See* BULLOCK GEAR.

Horsehair. Used for mixing with plaster to give increased strength, and with loam in foundry work to give porosity to cores.

Horse Power (*Eng.*) The unit of power in engineering; equal to 33,000 foot pounds of work per minute.

Hose. Flexible tubing of canvas, rubber, leather, etc., used for the conveyance of a liquid.

Hose Coupling. Metal joints used for connecting two lengths of hose. The connection may be made by a screw thread or by some form of joint or clip, which is more rapidly fastened.

Hose Pipe Tyres (*Cycles*). A colloquial expression for a single tube tyre. *See* TYRES.

Host (*Botany, Zool.*) An animal or a plant which has a parasite or commensal living upon it.

Hot Air Engine (*Eng.*) A form of motor now practically obsolete. Air is heated in some form of metal vessel, and supplied to a single acting cylinder (with piston and valves somewhat like a gas engine), in which the expansion of the air produces the motion of the piston.

Hot Metal (*Eng.*) Metal of any kind is said to be "hot" when it is at a temperature sufficiently high for some definite operation to be carried out. Thus a smith may say iron is hot when it is just at a welding or a forging heat, and not hot if below this temperature, though, of course, it is then extremely hot in the ordinary usage of the word.

Hot Plate (*Build.*) The top of a stove.

Hot Rolling (*Print.*) A process of drying and pressing by means of hot rolls.

Hot Short *or* **Red Short** (*Met.*) Iron which is brittle when hot, usually owing to the presence of sulphur.

Hot Water System (*Hygiene*). A method of warming effected by means of hot water or steam circulating in a system of closed pipes. The circulation depends upon the water being hotter, and therefore lighter, in the pipe through which it leaves the boiler than in that which brings it back. Some 12 ft. of 4 in. pipe are required per 1,000 cubic feet of air space in dwelling rooms to give a temperature of about 65°.

Hot Water Test (*Eng.*) Testing the joints of a boiler by forcing hot water in under pressure. A boiler may not leak when cold, but the expansion of its joints may make it very leaky when hot; hence the importance of this test before any attempt is made to get up steam.

Hot Waves (*Meteorol.*) Waves of exceptionally hot air which travel over countries and raise the local mean temperature to a great extent. New York, for instance, suffers from them, being so situated that the hot winds reach the city after travelling across the whole of the United States, an area which becomes greatly heated in midsummer.

Hot Well (*Eng.*) The receptacle for the hot water and condensed steam from the condenser of an engine.

Hour. *See* WEIGHTS AND MEASURES.

Hour Angle (*Astron.*) The angle which the declination circle of any celestial body makes with the meridian. It may be reckoned in degrees, but is usually expressed in time; *e.g.* if the hour angle is 21 hrs. 35 min., it is meant that 21 hrs. 35 min. have elapsed since the star crossed the meridian.

Hour Circles (*Astron.*) Great circles of the celestial sphere which pass through the poles like the meridians of the earth, and are therefore perpendicular to the celestial equator.

Household Soap. A term applied generally to all ordinary hard soaps that are used for domestic, household, or laundry purposes, and in contradistinction to toilet soaps, medicinal soaps, soft and industrial soaps (*q.v.*) *See also* MOTTLED SOAP, PRIMROSE SOAP, YELLOW SOAP, WHITE SOAP, *and* SOAP MANUFACTURE.

House Marks (*Typog.*) Corrections to be made in proofs which the piece-hand does not undertake to execute.

House Painting. This business is often carried on in connection with general building or plumbing, although this is not the case in the north of England and Scotland. The duties of the house painter include painting, paperhanging, distempering, staining, and graining; frequently sign writing, gilding, and marbling, and sometimes glass embossing are also carried on in connection with the business. Although the work of the painter is essential to the proper finish of every residence from a decorative point of view, and every other building from the point of preserving it by an application of paint, yet probably 75 per cent. of his work consists in cleaning and renovating. In painting new woodwork the constituents of the paint are varied according to the surface to which it is to be applied (*see* PAINT MIXING); but new woodwork is usually given four coats of paint. The first is called PRIMING, and is applied after the surface of the wood has been rubbed down with sandpaper, and knots have been covered with shellac dissolved in methylated spirits or naphtha (termed KNOTTING), or silver leaf, to prevent the exudation of resin. The priming coat is mixed with plenty of oil, so that it can penetrate the wood: frequently a proportion of red lead is contained in it with patent driers (*q.v.*), and it is thinned with raw linseed oil

and turpentine. After the priming coat is dry, the work is STOPPED; *i.e.* all nail holes and depressions are stopped with ordinary putty (*q.v.*) or white lead putty. The second, third, and subsequent coats are then given, ample time being allowed between each to permit of thorough drying, and the surface is then rubbed down with sandpaper, so as to render it perfectly level. The basis of the paint mostly employed is white lead, which has long remained in use because of its body (*q.v.*), or property of masking or hiding the surface to which it is applied. The poisonous nature of white lead, however, is a serious objection to it, and zinc white is rapidly growing in favour. The various earth colours (*q.v.*) or natural pigments, such as ochres, siennas, umbers, etc., are also employed to a considerable extent. If the base is white, it is usually necessary to add one or more colours to produce the required tint. *See* PAINT MIXING. After three coats of paint have been given, the woodwork is sometimes varnished, although this is usually deemed unnecessary when the paint is properly mixed. When a flat colour, or one without gloss, is required, oil in the final coat is omitted, and turpentine is employed alone to render the paint of a suitable thin consistency. Flatted work on large surfaces, such as the wall of an apartment, possesses the advantage of hiding inequalities of the surface much better than a glossy paint would. In this case the paint is usually stippled (*q.v.*) In finishing fine work, the best results are usually obtained by applying several coats in the manner described, and finishing the last one flat or without gloss, finally varnishing the whole surface. This tends to preventing blistering, while the finish is superior to that obtained in the ordinary way. In painting on plaster it is important that the surface be free from moisture; but four or five coats of paint are usually required in order to produce a satisfactory result, as the plaster is much more absorptive than wood, and increased quantity of oil and turpentine is necessary. In painting on iron, on the contrary, a smaller proportion of thinners (*q.v.*) is required. *See* IRON WORK PAINTING. DISTEMPERING is the art of painting in water colours. Distemper is made from pigments diluted with water, to which has been added some substance such as size to bind the particles of the pigments together. The pigment usually employed for distemper is whiting, which possesses considerable body when mixed with water, although very poor body when mixed with oil. The whiting is broken up in small pieces, and allowed to soak in water, and then stirred and broken up until of uniform consistency. Ordinary size melted, but not boiled, is then poured in; and if the distemper is to be coloured, the tinting colour is now added, and the whole thoroughly stirred up, and finally strained, when it is ready for use. The size must be of good quality, and only a little used, or the distemper will be apt to flake. Before the distemper is applied, it is usual to give plaster or other work a coat of clairecolle (*q.v.*) to prevent absorption. The application of distemper requires some practice to prevent laps and streaks showing and to get the surface uniform. Some colours cannot be used for distemper, as the whiting destroys them. The following is a list of the colours which may be safely employed for this work: Yellow ochre, sienna, umber, Vandyke brown, cadmium yellow, vermilion, red lead, Venetian red, Indian red, ultramarine blue, chrome green, emerald green, and all black pigments. The custom in many parts of the country in distempering a ceiling is to add a little ultramarine blue or black, in order to get rid of the yellow cast. This practice, however, is not to be recommended. If a perfectly white ceiling is required, a little blue may be added, provided that the surface of the walls is blue. In other cases the rule is to add to the white washable distemper a little of the same colour as that which prevails on the wall. This renders the surface of the ceiling apparently quite white. Of late years the use of washable distempers has increased enormously. These are distemper colours, sold ready for use or requiring only the addition of water. They are made in a large variety of colours, ranging from the most brilliant red down to pale yellows, greens, and greys, and include in their composition size, casein, or other binding material which renders them washable after they have been on the wall for some weeks. In interior decoration this class of paint is rapidly increasing in use, and a wall finished in some of the bright colours has a firm and pleasing appearance, much more satisfactory than wallpaper, and much more durable. *See also* RELIEF DECORATION, VARNISHING, MARBLING, GRAINING, PAPER HANGING, WALLPAPERS, PAINTERS' BRUSHES.

Houses Let in Lodgings. By Sec. 94 of the Public Health (London) Act, 1891, sanitary authorities are empowered to make byelaws: (*a*) for regulating the number of persons and separation of the sexes in a house or part of a house let in lodgings; (*b*) for the registration and inspection of such houses; (*c*) for drainage, cleanliness, and ventilation; (*d*) for cleansing and limewashing at stated times; (*e*) for taking precautions in case of infectious disease.

Housing (*Carp. and Join.*) A form of joint where the whole thickness of one piece is let into another piece. The ends of the treads and risers of a staircase are housed into the wall string (*q.v.*), *i.e.* the ends of these boards are fitted into grooves cut in the string.

H.P. (*Eng.*) The symbol for horse power (*q.v.*)

Hubs (*Cycle*). *See* CYCLES.

Huckaback (*Cotton Manufac.*) A standard weave for giving a rough feel and appearance to a cloth, which, however, is firmly bound. Used for towels, etc.

—— (*Linen Manufac.*) This is an old standard pattern used for towellings. It is a mixture of plain cloth and a little float, which gives the cloth a fine spot appearance with a rough surface, and makes it specially suited for the purpose for which it is intended.

Huddlestone Stone. *See* BUILDING STONE.

Hue (*Dec.*) A word used as a qualifying term in connection with colour; thus, if two crimsons are compared, one of them may be said to have a redder hue than the other. Strictly speaking, hue is the result of compounding two or more colours, which thus form hues of the particular colour which predominates. The word hue is frequently employed as a synonym for colour.

—— (*Light*). The true tint or colour of light. *See* COLOUR.

Humerus (*Zoology*). The large bone of the fore limb. It articulates with the shoulder girdle, and at the other extremity with the RADIUS and ULNA (*q.v.*)

Humetté (*Her.*) An ordinary "couped" so that it does not extend to the edge of the shield. Used chiefly of a fesse.

Humidity (*Meteorol., Phys.*) The humidity of the air is the amount of moisture which it contains.

The three terms often used in speaking of atmospheric moisture are: (1) ABSOLUTE HUMIDITY, the actual amount of water contained (in the form of vapour) in a given volume of air. (2) RELATIVE HUMIDITY, the ratio of the amount of moisture actually present to the amount necessary to cause saturation. (3) DEW POINT (*q.v.*)

Humour, Aqueous. The fluid filling the smaller anterior chamber of the eye, between the cornea and the crystalline lens.

——, Vitreous. The delicate jelly-like substance filling the larger posterior chamber of the eye, between the crystalline lens and the retina.

Hundredweight. *See* WEIGHTS AND MEASURES.

Hung (*Carp and Join.*) A term denoting that a door is fixed on hinges.

Hunter's Moon (*Astron.*) The full moon following the harvest moon (*q.v.*) rises in a manner similar to the latter; the peculiarity, however, is less noticeable than it is in the case of the harvest moon.

Hunting (*Eng.*) Variations of speed of an engine when the governor is not controlling it efficiently, *i.e.* when the governor is slowing the engine down and it goes on losing speed too long; when the governor is acting so as to increase the speed, and the speed goes on increasing beyond the proper amount. Under these circumstances the governor requires alteration.

Hunting Cog (*Eng.*) The provision of an extra tooth (the hunting cog) in a toothed wheel, so that the number of teeth on the wheel is not an exact multiple of those on the pinion. This prevents the same set of teeth from coming continually into contact, and equalises the wear.

Hurricanes (*Meteorol.*) When cyclones in the torrid zones reach their greatest development they are called by this name. These atmospheric whirls vary from a few miles to several hundred miles in diameter, and are accompanied by great violence of wind and torrential rainfall. Frequent in the West Indies.

Hyacinth (*Min.*) A transparent red variety of ZIRCON (*q.v.*), used as a gem. *See also* CINNAMON STONE.

Hyalite (*Min.*) A colourless glassy variety of Opal (*q.v.*), occurring as a mammillated incrustation.

Hydra (*Her.*) A fabulous heraldic beast. A dragon with seven heads.

Hydracrylic Acid (*Chem.*)

$$\begin{array}{l} CH_2OH \\ | \\ CH_2 \quad (\beta\text{-oxypropionic acid, or } \beta\text{-lactic acid}). \\ | \\ COOH \end{array}$$

A syrupy liquid having properties both of an acid and an alcohol: it is isomeric with lactic acid. It is obtained by boiling acrylic acid with dilute caustic soda: $CH_2 = CH - COOH + H_2O = CH_2OH.CH_2.COOH$. Also ethylene as follows:

$$\begin{array}{c} CH_2 \\ \| \\ CH_2 \end{array} \xrightarrow{HOCl} \begin{array}{c} CH_2Cl \\ | \\ CH_2OH \end{array} \xrightarrow{KOH} \begin{array}{c} CH_2 \\ | \\ CH_2 \end{array}\!\!>\!O$$

$$\xrightarrow{HCN} \begin{array}{c} CH_2OH \\ | \\ CH_2CN \end{array} \xrightarrow[\text{Acid.}]{\text{Dilute}} \begin{array}{c} CH_2OH \\ | \\ CH_2 \\ | \\ COOH. \end{array}$$

Hydramine (*Photo.*) A name given to a substance formed by mixing together hydroquinone and para-diamidobenzene, $C_6H_4(NH_2)_2$. It crystallises in thin plates which are slightly soluble in cold water, but more easily in presence of sodium sulphite, and still more so with caustic alkali. It will develop an image by itself when simply dissolved in water. Caustic lithia, however, is usually employed with it as well as sodium sulphite. The following formulæ is recommended: Hydramine, 2·16 grains; sodium sulphite, 13·4 grains; caustic lithia, 1·25 grains; water, 1 oz.

Hydrant. A stand pipe connected to a water main, and intended to afford a supply of water in case of fire.

Hydrargyrum (*Chem.*) The Latin name for mercury. From it is derived the symbol for mercury, Hg. *See* MERCURY.

Hydrastine (*Chem.*). $C_{21}H_{21}NO_6$. A well crystallised (rhombic prisms) alkaloid, occurring along with berberine in *Hydrastis canadensis*. Melts at 132°. It is lævorotatory in chloroform solution. When administered it contracts the blood vessels. It is the active principle in the alcoholic extract of the hydrastis root used in medicine. The constitution of this alkaloid is known, but is too complex to be given here; it is an isoquinoline derivative.

Hydrated (*Chem., Min., etc.*) Combined with (or in some cases mixed with) water.

Hydraulic Accumulator (*Eng.*) A reservoir in the form of a large vertical cylinder. furnished with a heavily loaded piston. Water forced into the vessel by means of powerful pumps is maintained at a constant pressure, which is determined by the amount of load on the piston.

Hydraulic Belt (*Eng.*) A belt of some porous material, driven at a very high speed, with one part dipping into water. The belt "licks up" the water, and a layer of water adheres to the belt and can be raised to a high level, thus serving as a pump which has no valves or passages liable to be choked up by impurities.

Hydraulic Crane (*Eng.*) A crane in which the chain is moved by a hydraulic press or ram. The powerful short stroke of the ram is converted into a long movement of the chain by an arrangement of pulley blocks.

Hydraulic Leather. A CUP LEATHER. *See* HYDRAULIC PRESS.

Hydraulic Lime (*Build.*) Lime that is capable of setting under water. *See* CEMENTS.

Hydraulic Limestone (*Geol.*) Any limestone whose composition fits it for the manufacture of a cement which will set under water. *See also* CEMENTS.

Hydraulic Machinery (*Eng.*) A term applied to presses, rams, etc., which are worked by water forced in under pressure. The pressure is maintained by a reservoir at a high level, or a hydraulic accumulator (*q.v.*), into which the water is forced by a pump worked by an engine.

Hydraulic Main (*Gas Manufac.*) *See* GAS MANUFACTURE.

Hydraulic Mean Depth. The hydraulic mean depth of a pipe of any shape equals the sectional area of the current of fluid divided by the wetted perimeter. In circular pipes it is always one-fourth of the diameter; in pipes of oval or elliptical

section, such as egg-shaped sewers, it varies according to the level of the liquid flowing in them.

Hydraulic Motor (*Eng.*) A small engine driven by water under pressure. It may be either of the reciprocating type, with cylinder and piston, or some form of turbine (*q.v.*)

Hydraulic Press *or* **Ram.** Most hydraulic machinery depends for its motion upon a cylinder which is of one well marked type, shown in the illustration (fig. 1). A heavy casting A forms the cylinder, bored out at B to make a smooth fit with the RAM or piston C. This piston carries the HEAD D, which possesses a broad flat surface if used for raising weights or for compressing any material. At E the cylinder has a channel bored out in the metal, and this channel contains the CUP LEATHER shown in section in fig. 2. The water forces this leather into close contact with the inside of the channel E and the ram C, thus making a watertight joint. Water enters at F, being forced in by a pump, or from a reservoir or accumulator, in which it is stored under pressure.

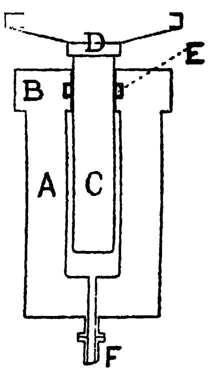


Fig. 1.

If the ram is required for working a crane, the head D is replaced by a set of pulley blocks, over which runs a chain so arranged as to multiply the motion of the ram to any extent required. For example, the motion may be multiplied four times, so that if the ram move 1 ft. the end of the chain moves 4 ft. The head D may carry dies used in shaping metal, either cold or hot, thus forming a HYDRAULIC FORGING PRESS. It may be connected directly to a lift, forming a HYDRAULIC LIFT, in which case the cylinder is elongated so as to have a length of stroke equal to the height of the lift, or else the lift may be raised by tackle similar to that of the hydraulic crane. This arrangement is often termed a HYDRAULIC HOIST. A small press for raising weights is termed a HYDRAULIC JACK, and is often portable, being driven by a hand pump. The tubing F is usually a thick walled pipe of iron or steel, often called HYDRAULIC TUBE, even when used for other purposes.

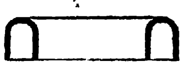

Fig. 2.

Hydraulics (*Eng.*) The science dealing with liquids in motion, in connection with their useful application, as distinguished from hydrodynamics (*q.v.*)

Hydrazine (*Chem.*), $H_2N.NH_2$ (Diamide). Probably a gas; best known as the hydrate $N_2H_4.H_2O$, a colourless, fuming liquid. Boils at 118° at 739 mm. When heated the hydrate attacks glass, and destroys cork and rubber. Powerful reducing agent; strong diacid base. Prepared from aminoguanidine, $HN=C\langle^{NH.NH_2}_{NH_2}$ (*see* GUANIDINE), by boiling with strong caustic soda solution, and adding sulphuric acid to cooled solution to obtain hydrazine sulphate. The latter compound is distilled with caustic potash solution in silver retort with silver condenser.

Hydrazines (*Chem.*) Substitution products of hydrazine, but they are not formed as a rule directly from hydrazine; *e.g.* hydrazobenzene (*q.v.*) is symmetrical diphenylhydrazine. *See also* PHENYLHYDRAZINE.

Hydrazobenzene (*Chem.*), $C_6H_5NH.NH.C_6H_5$. Colourless leaves; melts at 131°; camphorlike smell; oxidised in moist air to azobenze; insoluble in water; soluble in alcohol and in ether. Strong acids convert it into benzidine (*q.v.*) On reduction it yields aniline. It may be prepared by reduction of nitrobenzene (*a*) by zinc dust and caustic soda solution; (*b*) by electrolysis, using copper cathode and lead anode, the former being immersed in an alcoholic solution of nitrobenzene containing a little sodium acetate, and the latter in a porous pot containing strong sodium carbonate solution.

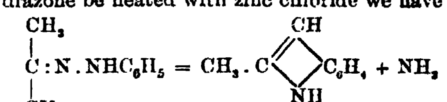
Hydrazoic Acid (*Chem.*) AZOIMIDE (*q.v.*)

Hydrazones (*Chem.*) Compounds formed from organic substances of various classes which contain the carboxyl group $(-CO-)$ by union with phenylhydrazine and elimination of water. Thus aldehydes and ketones of every kind form hydrazones, and their formation is used in deciding whether a substance is an aldehyde or a ketone. Examples of the formation of hydrazones are:

$$\begin{array}{l} CH_3 \\ | \\ CO \end{array} + \underset{\text{Phenylhydrazine.}}{H_2N.NHC_6H_5} = \underset{\text{Aldehyde Hydrazone.}}{\begin{array}{l} CH_3 \\ | \\ C:N.NHC_6H_5 \\ | \\ H \end{array}} + H_2O$$

$$\begin{array}{l} CH_3 \\ | \\ CO \\ | \\ CH_3 \end{array} + H_2N.NHC_6H_5 = \underset{\text{Acetone Hydrazone.}}{\begin{array}{l} CH_3 \\ | \\ C:N.NHC_6H_5 \\ | \\ CH_3 \end{array}} + H_2O$$

These two hydrazones are crystalline solids. The hydrazones revert to their constituents when heated with dilute acids. They readily form heterocyclic compounds with loss of ammonia; then if acetone hydrazone be heated with zinc chloride we have:



a-Methyl Indole.

For another example of a hydrazone *see* ETHYL ACETOACETATE. The dihydrazones are called osazones (*q.v.*)

Hydrides (*Chem.*) Compounds of two elements, one of which is hydrogen. The non-metallic hydrides are gases or liquids, *e.g.* H_2O, HCl, NH_3; the metallic hydrides are solids, usually unstable.

Hydriodic Acid, Hydrogen Iodide (*Chem.*), HI. A colourless gas; pungent odour; liquefies at 0° under a pressure of 4 atmospheres; solidifies at −55°. The gas is 4·4 times heavier than air: much more readily decomposed by heat than either hydrochloric or hydrobromic acids. It is also decomposed by sunlight. It is very soluble in water, the solution forming a strong acid, and, unlike the two acids just mentioned, it dissolves silver. The solution is decomposed by sulphuric acid thus:

$$2HI + H_2SO_4 = I_2 + 2H_2O + SO_2.$$

The strong solution is much used as a reducing agent in organic chemistry. Thus it reduces iodoform to methylene iodide, $CHI_3 + HI = CH_2I_2 + I_2$, and tartaric acid to malic acid, and then to succinic acid (*q.v.*) The acid is prepared by precisely similar methods to hydrobromic acid (*q.v.*) Its salts are called iodides (inorganic) or hydriodides (organic).

Hydrobromic Acid, Hydrogen Bromide (*Chem.*), HBr. A colourless gas; irritating smell; fumes in air; liquefies at $-69°$. Very soluble in water, forming the ordinary hydrobromic acid solution, which has similar properties to hydrochloric acid, but is decomposed by *strong* sulphuric acid.

$$H_2SO_4 + 2HBr = 2H_2O + SO_2 + Br_2.$$

It may be obtained by passing hydrogen and bromine vapour over heated platinum; by action of sulphur dioxide upon bromine in water (reverse of equation given above); by dropping bromine into mixture of water and amorphous phosphorus, and passing the gas evolved over moist amorphous phosphorus to remove bromine vapour.

$$P + 5Br + 4H_2O = 5HBr + H_3PO_4.$$

Hydrocarbons. Compounds of carbon and hydrogen. The possible number of these compounds is infinite; the known number is very large. To understand how it is that carbon can form an unlimited number of compounds with hydrogen, it must be remembered that the carbon atom is tetravalent, that is, it has the power of combining with four atoms of hydrogen or three atoms of hydrogen and one other atom or group equivalent in combining value to one atom of hydrogen, and so on; that carbon atoms have a unique power of combining with one another, and that they can do this in three different ways, *viz.* two atoms can combine together with one combining unit of each, giving what is called the *single linking*, or with two combining units of each giving the *double linking*, or with three combining units of each giving the *treble linking*. The following classes of hydrocarbons exist:—(1) OPEN CHAIN HYDROCARBONS: (*a*) Saturated, (*b*) Unsaturated. (2) CLOSED CHAIN HYDROCARBONS *or* CYCLIC HYDROCARBONS. In the first class the carbon atoms are so united that they do not form a closed figure or ring. The saturated hydrocarbons of this class are called paraffins (*q.v.*); they may all be regarded as derived from the first member, methane, CH_4. Suppose two hydrogen atoms are removed, one from each of two molecules of methane, and the residues united, we get the next member, ethane, C_2H_6,

$$CH_3 + CH_3 \qquad CH_3 - CH_3.$$
$$H \qquad H$$

This process can be repeated indefinitely. The member next to ethane is propane, C_3H_8. If it is written $CH_3 . CH_2 . CH_3$, we see that two different hydrocarbons will result, according as we now replace a terminal hydrogen atom by CH_3 or a central hydrogen by CH_3, thus:

$$CH_3 . CH_2 . CH_2 . CH_3 \qquad \begin{matrix} CH_3 \\ CH_3 \end{matrix}\!\!\Big\rangle CH . CH_3.$$

The compounds so produced are different, but both have the formula C_4H_{10}. The first is called butane, and the second isobutane. As we pass up the series the number of hydrocarbons having the same empirical formula, but different constitutional formulæ increase very rapidly. There are 802 hydrocarbons of the formula $C_{13}H_{28}$. These hydrocarbons are called saturated, because every carbon atom is united to its maximum number of hydrogen atoms, and the carbon atoms are "singly linked" together. If from two molecules of methane we take away from each two hydrogen atoms and unite the residues thus:

$$\begin{matrix} H_2 & CH_2 & CH_2 \\ H_2 & CH_2 & CH_2 \end{matrix}$$

we have the unsaturated hydrocarbon ethylene, C_2H_4. It is called unsaturated because each carbon atom has the power to unite with one hydrogen atom to form the saturated hydrocarbon ethane; also its carbon atoms are said to be "doubly linked." A series of hydrocarbons can be derived from ethylene by the same procedure as the paraffins are derived from methane: they are called olefines (*q.v.*) In a precisely similar way the acetylenes (*q.v.*) arise. The closed chain hydrocarbons have their carbon atoms joined in such a way as to form a closed figure or ring. In the hydrocarbon hexane, $CH_3 . CH_2 . CH_2 . CH_2 . CH_2 . CH_3$, if one hydrogen atom be removed from each terminal carbon atom these will unite, and the six carbon atoms form a ring,

$$\begin{matrix} & CH_2 & \\ & & CH_2 \\ H_2C & & CH_2 \\ & CH_2 & \end{matrix}$$

hexamethylene (*q.v.*) This compound is a derivative of benzene (*q.v.*), in which the carbon atoms are known to be united in a ring. The number of these cyclic hydrocarbons is very large. For examples, *see* TRIMETHYLENE, BENZENE, NAPHTHALENE, ANTHRACENE. For simplicity we have spoken in what has gone before of the removal of hydrogen atoms; in fact, this is done indirectly. Halogens are first introduced, generally bromine or iodine, and these removed by sodium or other appropriate reagents. *See* PARAFFINS, OLEFINES, ACETYLENES, *and also* FOODS.

Hydrocarbons, Native (*Geol.*) A general term applied to coal, lignite, brown coal, oil shale, and other carbonaceous deposits of sedimentary origin, as well as to any of a large series of hydrocarbon compounds of somewhat more definite chemical composition, which occur in the mineral state. Amongst these may be instanced amber, petroleum, asphaltum, elastic bitumen, jet, etc.

Hydrochloric Acid (*Chem.*), HCl. Also termed HYDROGEN CHLORIDE, SPIRITS OF SALT, MURIATIC ACID. A colourless gas with keen acid smell; liquefies under a pressure of 40 atmospheres at 10°; solidifies at $-115°$. The dry gas and the liquid are, chemically speaking, very inactive—do not redden litmus nor attack metals. The gas is very soluble in water: at 0° and 760 mm. 1 volume of water dissolves 503 volumes of hydrogen chloride, or under the same conditions 1 gram of water dissolves ·825 grs. of the gas. The moist gas or its solution in water behaves as a strong acid. *See* ACID. The gas is partly decomposed (dissociated) above 1500°; when not perfectly dry, it is decomposed by sodium, giving half its volume of hydrogen. To obtain it on the large scale common salt is heated with sulphuric acid. *See under* ALKALI. In the laboratory it is prepared by heating common salt with sulphuric acid in a glass flask, and passing the gas evolved through a small quantity of water to wash it, $NaCl + H_2SO_4 = NaHSO_4 + HCl$. The gas can be dried by passing it over calcium chloride or through concentrated sulphuric acid. It is also produced when any chloride (except silver chloride and mercuric chloride) is heated with sulphuric acid; when chlorine acts upon hydrocarbons, forming substitution

products, *e.g.* $CH_4 + Cl_2 = CH_3Cl + HCl$; and when hydrogen and chlorine (not absolutely dry) are mixed together in equal volumes and exposed to a bright light. In the latter case, if the illumination is momentary only, a sudden expansion occurs, and the mixture recovers its original volume ("Draper effect"), only a trace of hydrogen chloride being formed. Its salts are called chlorides in inorganic chemistry; hydrochlorides in organic chemistry.

Hydrocyanic Acid, Prussic Acid (*Chem.*), HCN. Colourless liquid, said to have smell of almonds; but people differ enormously in their sensibility to the smell. Boils at 26°; solidifies at −15°; one of the most poisonous substances known; burns with violet flame; mixable with water in all proportions, contraction occurring. On keeping, the dilute acid undergoes hydrolysis (*q.v.*), forming ammonium formate and other substances:

$$HCN + 2H_2O = HCOONH_4.$$

It occurs as a product of hydrolysis of the glucoside amygdalin (*q.v.*) Oil of bitter almonds prepared from this substance may contain in a crude state up to 15 per cent. of the acid. The acid is prepared by distilling potassium ferrocyanide with dilute sulphuric acid:

$$2K_4Fe(CN)_6 + 3H_2SO_4 = K_2Fe \,.\, Fe(CN)_6 + 6HCN.$$

If the acid is required anhydrous it can be dried over calcium chloride. The British Pharmacopœia acid is 2 per cent. hydrocyanic acid. The salts are called CYANIDES.

Hydrodynamics. The purely theoretical science dealing with the motion of fluids.

Hydroferricyanic Acid (*Chem.*), $H_3Fe(CN)_6$. Shining brownish green needles; soluble in water and in alcohol; insoluble in ether; it is unstable. Obtained by adding sulphuric acid to lead ferricyanides, or by adding concentrated hydrochloric acid to a cold saturated solution of potassium ferricyanide. It is doubtful if the pure acid has been obtained. Its salts are called FERRICYANIDES.

Hydroferrocyanic Acid (*Chem.*), $H_4Fe(CN)_6$. White pearly leaflets; soluble in water and in alcohol; insoluble in ether. It is a strong tetrabasic acid; decomposes on heating to 400° C. into hydrocyanic acid and the compound $H \,.\, Fe(CN)_5$. It is obtained by saturating a concentrated solution of potassium ferrocyanide with ether, and adding excess of hydrochloric acid. The precipitate obtained is repeatedly dissolved in water and precipitated by ether. Its salts are called FERROCYANIDES.

Hydrofluoric Acid (*Chem.*), HF. A colourless liquid; boils at 19·5°; fumes in air. The fumes are very dangerous if inhaled: the liquid causes sores if dropped on the skin. It does not attack glass if perfectly anhydrous; but the presence of a trace of water causes it to do so with great avidity. On this account the strong acid is kept in platinum vessels; the dilute acid can be kept in guttapercha bottles. The action upon glass is as follows: The silica gives silicon tetrafluoride (a gas); the sodium and calcium are converted into fluorides.

$$SiO_2 + 4HF = SiF_4 + 2H_2O$$
$$Na_2O + 2HF = 2NaF + H_2O$$
$$CaO + 2HF = CaF_2 + H_2O$$

The vapour density of the acid is two and a half times the normal, just above the boiling point, but becomes normal at 90°. The anhydrous acid is prepared by heating the acid potassium fluoride (HF . KF) in a platinum retort with a condenser and receiver of the same metal, a freezing mixture being used to condense the acid. The dilute acid is obtained by heating calcium fluoride (fluorspar) with sulphuric acid in a lead apparatus. The acid is used for etching on glass. The salts of hydrofluoric acid are called FLUORIDES; most metallic fluorides are soluble in water; only those of the alkaline earths are insoluble, and are obtained by dissolving the carbonate in hydrofluoric acid, or, in case of the insoluble fluorides, by precipitating a soluble salt of the metal with a soluble fluoride. Calcium fluoride is insoluble in water, while the other halogen calcium salts are very soluble. Silver fluoride is soluble, while the other halogen silver salts are insoluble.

Hydrofluosilicic Acid (*Chem.*), H_2SiF_6. Only known in solution; the strong solution fumes in air. It is prepared by dissolving silica in hydrofluoric acid or by passing the gas silicon tetrafluoride into water and filtering from the gelatinous silicic acid formed at the same time, $SiF_4 + 4H_2O = H_2SiF_6 + H_4SiO_4$. It is occasionally used as a test for potassium and for barium, as solutions of the salts of these metals give colourless precipitates with hydrofluosilicic acid; *viz.* K_2SiF_6, potassium silicofluoride and $BaSiF_6$, barium silicofluoride. Potassium silicofluoride is used in the preparation of SILICON (*q.v.*)

Hydrogen (*Chem.*), H. Atomic weight, 1. A colourless odourless gas; the lightest substance known; very slightly soluble in water; when liquefied the liquid boils at −253° C., and the solid melts at −257° C.; the specific heat of the solid (obtained by calculation from latent heat of evaporation) is about 6, which is higher than that of any known substance. It readily unites with oxygen to form water, and the union is accompanied by evolution of much heat. Thus when a mixture of 2 volumes of hydrogen and 1 volume of oxygen is burned, we have the intensely hot oxyhydrogen flame; when hydrogen burns in air the flame is not so hot on account of the diluting action of the atmospheric nitrogen. Hydrogen combines readily with chlorine to form hydrogen chloride—another reaction which gives rise to much heat. Neither of these actions takes place if the gases are absolutely dry. On account of these reactions hydrogen is called a strong reducing agent. *See* REDUCTION. Thus, when passed over certain metallic oxides heated to redness, it unites with their oxygen, and the metal is set free; *e.g.* CuO, PbO, HgO. When passed over heated ferric chloride, it gives ferrous chloride and hydrochloric acid gas, $FeCl_3 + H = FeCl_2 + HCl$; or if zinc and hydrochloric acid are added to a solution of ferric chloride, the hydrogen which would be set free from the zinc and hydrochloric acid removes chlorine from the ferric chloride, producing ferrous chloride. This is an example of the use of NASCENT HYDROGEN; the hydrogen in this case reacts when it is in the ionic (*see* IONS) condition, that is before the hydrogen atoms have had time to form the stable hydrogen molecule. Hydrogen occurs to a minute extent free in the atmosphere, in a state of combination in water (⅑ part by weight), in all acids, and in all naturally occurring organic substances. It may be obtained: (1) By decomposition of water acidified with sulphuric acid by a current of electricity. (2) From water by the action of metals such as sodium, potassium, or calcium, which decompose water at the ordinary temperature, $2K + H_2O = 2KOH + H_2$, or by passing steam over iron, magne-

sium, and certain other metals heated to redness, $Mg + H_2O = MgO + H_2$. (3) By the action of acids (except nitric acid) on some of the commoner metals, such as zinc, iron, tin (not copper or lead), $Zn + 2HCl = ZnCl_2 + H_2$. (4) By heating aluminium or zinc with caustic soda solution. Hydrogen is used in filling balloons and airships, and in the oxyhydrogen flame. *See* OXYHYDROGEN FLAME *and* LIGHT. Acids are often called hydrogen salts; *e.g.* nitric acid is sometimes called hydrogen nitrate; sulphuric acid, hydrogen sulphate; and so on.

Hydrogen Chloride (*Chem.*) This name is generally used for hydrochloric acid gas. *See* HYDROCHLORIC ACID.

Hydrogen Dioxide (*Chem.*) HYDROGEN PEROXIDE (*q.v.*)

Hydrogen Disodium Phosphate (*Chem.*) The common phosphate of sodium. *See under* SODIUM COMPOUNDS.

Hydrogenium (*Chem.*) When palladium is heated in hydrogen it absorbs 930 times its own volume of the gas, and increases about 10 per cent. in volume. The name hydrogenium has been given to this absorbed hydrogen. The specific gravity of hydrogenium has been calculated to be ·62; this value is eight times that of liquid hydrogen.

Hydrogen Monoxide (*Chem.*) WATER (*q.v.*)

Hydrogen Nitrate (*Chem.*) NITRIC ACID (*q.v.*)

Hydrogen Peroxide, Hydrogen Dioxide (*Chem.*), H_2O_2. A colourless liquid; when pure it is about half as heavy again as water; it freezes at a very low temperature. The pure substance easily decomposes into water and oxygen; on complete decomposition it yields about 500 times its own volume of oxygen. Hydrogen peroxide is usually sold in two strengths, "20 volume" and "10 volume," meaning hydrogen peroxide of such strength that the first gives 20 times its own volume of oxygen when heated, and the second 10 times its volume. Hydrogen peroxide is soluble in ether. On account of the ease with which this substance yields oxygen, it is a powerful oxidising agent (*see* OXIDATION): thus it converts metals such as iron and magnesium into the hydroxides; it oxidises many lower oxides to higher oxides, as sulphur dioxide to sulphuric acid, arsenious oxide to arsenic acid, the action in the case of metallic oxides taking place in alkaline solution; it oxidises lead sulphide (black) to lead sulphate (white), hence its use in restoring oil paintings; it oxidises many organic substances, hence its use in bleaching hair, silk, ivory, etc., and as a dentrifice. With ozone and silver oxide a reduction occurs:

$$H_2O_2 + O_3 = H_2O + 2O_2;$$
$$Ag_2O + H_2O_2 = H_2O + 2Ag + O_2.$$

A number of finely divided and dry solids resolve hydrogen peroxide into water and oxygen without apparent change themselves; such are carbon, platinum, manganese dioxide. Hydrogen peroxide occurs in small quantity in the atmosphere. It is formed when a burning jet of hydrogen is allowed to impinge on a surface of ice cold water. It is usually prepared by adding barium peroxide gradually to cold dilute sulphuric acid, always keeping the latter in excess; the excess of acid can be removed by baryta water. The insoluble barium sulphate is filtered off, and the peroxide concentrated over sulphuric acid under reduced pressure. *See also* SODIUM DIOXIDE. The two best tests for hydrogen peroxide are: (1) It liberates iodine from potassium iodide, $H_2O_2 + 2KI = 2KOH + I_2$. (2) On adding chromic acid and then ether, the ether is coloured blue.

Hydrogen Phosphide. Another term for phosphoretted hydrogen. *See under* PHOSPHORUS COMPOUNDS.

Hydrogen Sulphate (*Chem.*) Another name for SULPHURIC ACID (*q.v.*)

Hydrogen Sulphide (*Chem.*) Another name for sulphuretted hydrogen. *See under* SULPHUR COMPOUNDS.

Hydrolysis (*Chem.*) The resolution of certain classes of organic compounds, such as esters, amides, and nitriles, into two simpler compounds by the fixation of the elements of water. When ethylacetate, for example, is boiled with water it yields alcohol and acetic acid, and the change may be supposed to take place thus:

$$\begin{array}{c} CH_3 \\ | \\ CO \\ | \\ OC_2H_5 \end{array} + HOH = \begin{array}{c} CH_3 \\ | \\ C \begin{array}{l} \diagup OH \\ \diagdown OH \end{array} \\ | \\ OC_2H_5 \end{array} = \begin{array}{c} CH_3 \\ | \\ C \begin{array}{l} \diagup OH \\ \diagdown\!\diagdown O \end{array} \end{array} + C_2H_5OH.$$

Similarly acetamide gives acetic acid and ammonia:

$$\begin{array}{c} CH_3 \\ | \\ CO \\ | \\ NH_2 \end{array} + HOH = \begin{array}{c} CH_3 \\ | \\ C \begin{array}{l} \diagup OH \\ \diagdown OH \end{array} \\ | \\ NH_2 \end{array} = \begin{array}{c} CH_3 \\ | \\ C \begin{array}{l} \diagup OH \\ \diagdown\!\diagdown O \end{array} \end{array} + NH_3.$$

The rate of hydrolysis is greatly accelerated by the presence of an alkali such as caustic soda, or an acid such as hydrochloric. In the case of ethylacetate the caustic soda would neutralise the acetic acid and thus prevent any reverse reaction; in the case of acetamide an acid would neutralise the ammonia.

Hydrometer (*Phys.*) An instrument for directly measuring the specific gravity of liquids. It consists of a graduated glass tube made to float vertically in the liquid by means of a hollow bulb below, suitably weighted with shot or mercury. The graduations are usually on a paper scale inside the sealed tube. Evidently the instrument will sink in any liquid until it displaces a volume of liquid equal to itself in weight; *i.e.* in a dense liquid it will sink to a smaller depth than in a less dense one. In order to avoid inconvenient lengths of stem, it is usual to employ distinct instruments (or a range of instruments) for liquids denser and less dense than water respectively. The earlier instruments of the kind were graduated in such a way that a calculation was required to give the specific gravity. *See* HYDROMETER SCALES. Now they are usually made direct reading, and are very useful for rapid determination when sufficient liquid is available and great accuracy is not essential.

——, Nicholson's. This instrument is of more interest theoretically than practically, and is really more suitable for taking the specific gravities of solids than for liquids. Its advantage is that it can be applied to either purpose. It is usually a brass cylindrical float, carrying scale pans above and below, the upper one being attached to the float by a narrow stem on which is a single fixed mark, and the whole weighted to float vertically. In use the instrument is floated in water, and weights placed in the upper scale pan until the fixed mark is level with the water surface; then it is placed in the liquid in question, and weights added or subtracted until the fixed mark

is again at the liquid level. Let W = weight of instrument, W_1 = weight required to sink it to fixed mark in water, and W_2 = weight required for the same purpose in the liquid;

$$\text{then } W + W_1 = \text{weight of water displaced}$$
$$W + W_2 = \quad ,, \quad ,, \text{ liquid displaced}$$

and the volume in each case is the same.

$$\therefore \text{ S.G. of the liquid} = \frac{W + W_2}{W + W_1}$$

In the case of a solid insoluble in water, a piece of it is placed in the upper pan, and weights removed until the fixed mark is level with the water surface. Then if W_3 be weight now in scale pan, the weight of the solid is $W_1 - W_3$. The solid is then placed in the lower pan, and weights added to upper pan until level is same as before. Let W_4 be weight now in scale pan, then weight of water displaced by solid is $W_4 - W_3$;

$$\text{hence S.G. of the solid is } \frac{W_1 - W_3}{W_4 - W_3}$$

Hydrometer Scales. These may be graduated to read off the specific gravity directly, *e.g.* in water the level of the liquid is opposite to the point marked 1 on the scale. In a liquid whose specific gravity is ·995 the level of the liquid is opposite to the graduation marked ·995, and so on. In many cases, however, water is taken as 1,000, and the reading in the case quoted then becomes 995. Several arbitrary scales are in use in various trades, *e.g.* those of BAUMÉ, BECK, CARTIER, and TWADDELL. To obtain the actual density of a liquid from the reading on any one of these scales, the following formulæ may be used; in each case the reading (in scale divisions or hydrometer degrees) is denoted by x.

Baumé's Scale (lighter than water) density $= \dfrac{144}{144 + x}$

(heavier ") $= \dfrac{144}{144 - x}$

Cartier's Scale $= \dfrac{136{\cdot}8}{126{\cdot}1 + x}$

Beck's Scale $= \dfrac{170}{170 \pm x}$

Twaddell's Scale ... $= \dfrac{100 + \frac{x}{2}}{100}$

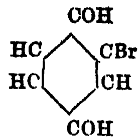
Thus let the density of a liquid be 30° Twaddell, then the actual value of the specific gravity is

$$\frac{100 + \frac{30}{2}}{100} = 1{\cdot}15.$$

Hydroquinone or Paradioxy Benzene (*Chem.*), $C_6H_4(OH)_2$; also called QUINOL. A white crystalline solid; melts at 169°; easily soluble in water, alcohol, or ether. It is a reducing agent, being oxidised to quinone. It occurs combined with glucose in the glucoside arbutin in the bearberry. It is obtained by reduction of quinone (*q.v.*) by sulphurous acid. *See* FOLLOWING.

—— (*Photo.*) This substance was first introduced as a developer for gelatine plates by Captain (now Sir William) Abney in 1880. It works well without the addition of bromide, giving negatives beautifully clean and of good colour. It has a tendency to give contrast, and for this reason is valuable in cases of over exposure.

Hydroquinone Br (*Photo.*) This is hydroquinone in which one atom of hydrogen has been replaced by bromine:



$(C_6H_2(OH)_2Br)$

It is said to produce softer negatives than hydroquinone itself.

Hydrostatics. The theory dealing with the forces exerted by or on fluids at rest.

Hydrothermal Action (*Geol.*) The chemical action set up in connection with rock masses below the surface by waters acting at temperatures and pressures which may often be sufficiently high to bring about solution of the rocks affected, and thus lead to their reconstruction in a crystalline form. In the cases in which alkaline matters are present in the thermal waters, hydrothermal action may give rise to the first stages in the formation of eruptive rocks.

Hydroxide (*Chem.*) A compound containing the hydroxyl group OH. Hydroxides may be acid or alkaline in character. The metallic hydroxides, such as those of potassium, sodium, calcium, etc., KOH, $NaOH$, $Ca(OH)_2$, are powerful alkalis; those of iron, aluminium, zinc, etc., $Fe(OH)_3$, $Al(OH)_3$, $Zn(OH)_2$, are basic in character. The non-metallic hydroxides are acids, such as boric acid, $B(OH)_3$; silicic acid, $Si(OH)_4$; sulphuric acid, $SO_2(OH)_2$, etc. In organic chemistry the basic hydroxides of inorganic chemistry are represented by the alcohols and quaternary ammonium bases, *e.g.* C_2H_5OH and $N(C_2H_5)_4OH$, the former acting as weak bases and the latter as powerful alkalis. The acid hydroxides are represented by the carboxylic acids, *e.g.* CH_3COOH, which is acetic acid. In organic nomenclature the name hydroxyl for the OH group is often shortened to "oxy"; thus glycollic acid, $CH_2OH.COOH$, is often called oxyacetic acid.

Hydroxy (*Chem.*) A prefix applied to denote the presence of the hydroxyl group (–OH) in a compound. The word is often shortened to "oxy." Thus tartaric acid is sometimes called dihydroxysuccinic or dioxysuccinic acid.

CH_2COOH	CHOHCOOH
|	|
CH_2COOH	CHOHCOOH
Succinic Acid.	Tartaric Acid.

Hydroxyl (*Chem.*) The name given to the group –OH. *See under* HYDROXIDE.

Hydroxylamine (*Chem.*), NH_2OH. A white crystalline solid; melts at 33°; boils at 5·8° under a pressure of 22 mm. of mercury; its vapour explodes at above 100°; deliquesces and decomposes on exposure to air; soluble in water, less soluble in alcohol, still less in ether. It is a powerful base, forming crystalline salts with acids. Oxidising agents set it on fire. Nitrous acid yields with it hyponitrous acid, which decomposes into nitrous oxide and water:

$$HO.NH_2 + ON.OH = HON:NOH + H_2O = N_2O + 2H_2O.$$

It is an extremely important reagent in organic chemistry; for information on this point *see* OXIMES. It may be prepared from hydroxylamine hydrochloride by dissolving the latter in methyl alcohol, adding sodium methoxide (CH_3ONa), filtering off the

precipitated common salt, and fractionally distilling the filtrate till a solid distillate is obtained. The hydrochloride is prepared best by mixing concentrated solutions of sodium nitrite (1 mol.) and sodium hydrogen sulphite (2 mols.), adding potassium chloride and allowing to stand, boiling the precipitate which forms for several hours with water. On cooling, potassium sulphate separates first; then hydroxylamine sulphate. The latter is purified by recrystallisation. From it the hydrochloride is obtained by addition of barium chloride, and after filtering off the barium sulphate, crystallising the solution of hydrochloride.

Hygrometer (*Phys.*) An instrument for measuring the amount of aqueous vapour in the air, or more frequently what is known as its HYGROMETRIC STATE (*q.v.*) The direct chemical method of separating a known volume of air through a series of drying tubes, and thus finding the amount of vapour present by the increase in weight, is seldom used on account of its slow and laborious nature, although it is very accurate. Most hygrometers, such as those of Daniell, Regnault, and Dines, are really instruments for finding the dewpoint, and depend upon cooling some surface in the open air until moisture is deposited upon it. An exception is the WET AND DRY BULB HYGROMETER, which depends upon the cooling produced by evaporation. The readings have to be reduced by the use of an empirical formula or tables.

——, **Daniell's.** One of the oldest forms of dewpoint hygrometers, now little used. It is practically a cryophorus, containing ether instead of water; *i.e.* a bent tube connecting two bulbs partly filled with ether and sealed up during boiling to expel air. One bulb is of black glass, and contains a delicate thermometer, and the other is covered with a muslin rag. In use the ether is collected in the blackened bulb, and the rag on the other bulb moistened with ether, the evaporation of which condenses the vapour within, and thus sets up rapid evaporation of the liquid in the blackened bulb, with a consequent fall of temperature. The temperature at which dew forms on the cooled bulb is noted, and also the temperature at which it disappears when evaporation ceases, the mean of the two being taken to be the dewpoint. This form of instrument is affected by many sources of error, and is practically obsolete.

——, **Regnault's.** One of the most accurate forms of dewpoint hygrometer, essentially consisting of a glass tube ending in a thin polished silver thimble, fitted with a stopper carrying a thermometer and also a small tube open to the air, both dipping below the surface of ether contained in the silver thimble. Air is aspirated through the ether, and thus its temperature, and that of the silver thimble, are lowered by evaporation, the formation of dew upon the outside being watched by means of a telescope at a distance An exactly similar empty tube, carrying a thermometer giving the temperature of the air at the time of the experiment, is mounted upon the same stand, a comparison of the two silver thimbles facilitating the exact determination of the instant at which the deposition of moisture occurs.

——, **Wet and Dry Bulb.** Consists of two thermometers mounted side by side, the bulb of one being kept moist by means of a loose cotton wick tied round it, the lower end of which dips into a vessel of water. On account of evaporation from the bulb this instrument is cooled, and indicates a lower temperature than the other, the difference depending upon the rate of evaporation and hence upon the amount of aqueous vapour present in the air. There is no simple relation between the readings and the hygrometric state; the latter is deduced therefore by reference to tables, although various empirical formulæ have been proposed. On account of its simplicity and convenience this form of hygrometer is largely used.

Hygrometric State *or* **Relative Humidity** (*Phys.*) The ratio of the amount of aqueous vapour actually present in air to the amount required for saturation at the existing temperature. This is practically the same as the ratio of the pressure of the aqueous vapour actually present to the pressure corresponding to saturation. It is generally determined by finding the "dewpoint," then hygrometric state =

$$\frac{\text{pressure of saturated vapour at dewpoint}}{\text{pressure of saturated vapour at temperature of air.}}$$

Hygrometry (*Meteorol.*) The determination of the amount of moisture that exists in the atmosphere as invisible vapour and as cloud.

Hygroscope (*Phys.*) An instrument which indicates a change in the amount of moisture present in the air. It usually depends for its action upon the property of absorbing aqueous vapour (with a consequent change of volume), possessed by many organic substances, such as hair, catgut, etc. Such instruments are generally incapable of giving exact measurements.

Hymenæa (*Botany*). A leguminous genus in the West Indies yielding timber and copal resin.

Hyoscine, Scopolamine (*Chem.*), $C_{17}H_{21}NO_4$. An alkaloid. Crystallises in white prisms, which melt at 59°. Soluble in water, alcohol, and ether. Lævorotatory. It occurs along with hyoscyamine in henbane leaves, and is prepared from these. On treatment with baryta water it yields tropic acid and a base of unknown constitution. Its hydrobromide is used in medicine. It dilates the pupil of the eye.

Hyoscyamine (*Chem.*), $C_{17}H_{23}NO_3$. An alkaloid isomeric with atropine (*q.v.*) Forms delicate white needles; somewhat soluble in water; it is lævorotatory. Baryta water resolves it into tropic acid and tropine, exactly the same as atropine is resolved into the same two substances; in fact, hyoscyamine is in all probability a compound of the lævorotatory modifications of tropine and tropic acid. It readily undergoes intramolecular rearrangement into atropine—for example, on simple melting. Like atropine, its solution dilates the pupil of the eye. Its sulphate is used in medicine.

Hypæthral (*Architect.*) A term applied to a temple when its cell or part of its cell is not roofed in. *See* CELL.

Hyperbola. The plane curve produced when a cone is cut by a plane which makes an angle with the base greater than that made by the slant side of the cone; also defined as the plane curve traced out by a point which moves so that its distance from a fixed point is always greater in a fixed ratio than its distance from a given fixed straight line.

Hyperbolic *or* **Natural Logarithm.** Logarithms calculated with the number 2·71828 . . . as a base. *See* LOGARITHMS. The hyperbolic logarithm enters into the calculation of the area of a hyperbola and many other mathematical computations. It

can be obtained by multiplying the common logarithm of the same number (given in tables of logarithms) by 2·3026.

Hypersthene (*Geol.*) One of the species of Pyroxene (allied to Augite) which crystallises in the orthorhombic system instead of the (normal) monosymmetric. It forms one of the constituents of the variety of Gabbro which is sometimes distinguished as Norite. It is a magnesium iron metasilicate (Mg . Fe)O . Si_2O. Silica = 54·2, magnesia = 24·1, ferrous oxide = 21·7 per cent. In colour it varies from green through black to brown. From Skye, Sweden, Saxony, etc.

Hypnone (*Chem.*) *See* ACETOPHENONE.

Hypo (*Photo.*) The name commonly applied in photography to SODIUM THIOSULPHATE, used for dissolving out the silver salts in fixing an image. *See under* THIOSULPHATES.

Hypobromites (*Chem.*) Salts of hypobromous acid. The hypobromites resemble in every way the hypochlorites (*q.v.*)

Hypochlorites (*Chem.*) Salts of HYPOCHLOROUS ACID (*q.v.*)

Hypochlorous Acid (*Chem.*), HOCl. Only known in water solution. Strong solutions are orange coloured; dilute solutions are colourless. The acid smells like bleaching powder solution. It is a very weak acid. On heating it easily decomposes into hydrochloric and chloric acids, but dilute solutions can be distilled without decomposition. On account of the ease with which it decomposes into oxygen and hydrochloric acid, it is a powerful bleaching agent and antiseptic. The acid is prepared by passing chlorine into water containing yellow mercuric oxide in suspension, then distilling the clear liquid; or dilute nitric acid is added to a solution of bleaching powder and the liquid distilled. It is present in chlorine water. Its salts, the hypochlorites, are obtained by acting upon metallic hydroxides with chlorine. They are oxidising agents, and on heating decompose into a chloride and a chlorate, $3KOCl = 2KCl + KClO_3$. Sodium hypochlorite is made by passing chlorine into cold and somewhat dilute caustic soda, and allowing the solution to crystallise. It always contains sodium chloride. $Cl_2 + 2NaOH = NaOCl + NaCl + H_2O$. It oxidises arsenic to arsenic acid; hence its use in Marsh's Test (*q.v.*) It oxidises urea (*q.v.*) and salts of chromium to chromates, $Cr_2(SO_4)_3 + 3NaOCl + 10NaOH = 2Na_2CrO_4 + 3NaCl + 3Na_2SO_4 + 5H_2O$. Bleaching powder (*q.v.*) yields calcium hypochlorite when it is dissolved in water.

Hypocrystalline Structure (*Geol.*) Occurs in rocks which consisted essentially of undifferentiated fluid material when they began to consolidate, but in which incipient crystallisation has commenced without being carried on to completion. Many pitchstones are of this nature.

Hypocycloid. The plane curve generated by a point in a circle which rolls round inside a larger circle. This curve is used for the lower part or flanks of the teeth of wheels.

Hypogyny (*Botany*). The condition in a flower when the calyx, corolla, and stamens arise upon the thalamus beneath the carpels.

Hyponitrous Acid, HO . N : N . OH. Has not been obtained pure; a solution is obtained by acting upon its silver salt with dilute hydrochloric acid. It easily decomposes nto nitrous oxide and water. The silver salt is formed as a yellow precipitate, when solutions of sodium nitrite and hydroxylamine sulphate are rapidly heated together to 60°, and silver nitrate added. *See* HYDROXYLAMINE.

Hypophosphites (*Chem.*) *See* HYPOPHOSPHOROUS ACID.

Hypophosphorous Acid (*Chem.*), H_3PO_2. A syrupy liquid which crystallises with difficulty. It is a powerful reducing agent, *e.g.* it reduces solutions of gold, silver, and mercury salts to the metals, and forms phosphoric acid. When heated, it yields phosphoretted hydrogen and phosphoric acid:

$$2H_3PO_2 = PH_3 + H_3PO_4.$$

It is a monobasic acid; its salts are called HYPOPHOSPHITES. The acid is obtained from barium hypophosphite by addition of dilute sulphuric acid, filtering off the barium sulphate, and carefully evaporating the solution. The hypophosphites are obtained by boiling phosphorus with a solution of the corresponding hydroxide, *e.g.*

$$P_4 + 3NaOH + 3H_2O = 3NaH_2PO_2 + PH_3$$
$$2P_4 + 3Ca(OH)_2 + 6H_2O = 3Ca(H_2PO_2)_2 + 2PH_3$$

They are crystalline solids; most of them are soluble in water. They are strong reducing agents. They are used in medicine.

Hypostyle (*Architect.*) A temple in which the roof is supported by internal columns.

Hyposulphites (*Chem.*) Salts of hyposulphurous acid. Zinc hyposulphite, ZnS_2O_4, is obtained when zinc dissolves in sulphurous acid, out of contact with air. Sodium hyposulphite, $Na_2S_2O_4$, is obtained by electrolysis of sodium hydrogen sulphite; it is used to reduce indigo in dyeing. Neither of these salts has been obtained pure. Sodium thiosulphate was formerly called sodium hyposulphite, and in trade it is still known under this name.

Hyposulphurous Acid (*Chem.*), $H_2S_2O_4$. A very unstable yellow liquid, formed when a solution of oxalic acid is added to a solution of a hyposulphite.

Hypotrachelium (*Architect.*) That part of a column immediately below the capital. The term is also used to denote the grooves worked below the neck of the Greek Doric column. *See* COLUMN.

Hypoxanthine (*Chem.*)  ((Sarcine) or 6-oxy-purine)

A white crystalline solid sparingly soluble in water. It occurs along with xanthine (*q.v.*) in the animal body, *e.g.* in the spleen, thymus, etc. It is a purine derivative (*see* PURINE), and can be prepared artificially from trichlorpurine.

Hypsometer (*Phys.*) A simple arrangement for conveniently observing the temperature indicated by a thermometer immersed in the steam from water boiling under atmospheric pressure, and used instead of a barometer for determining altitudes. It practically consists of a metal vessel for boiling the water, provided with concentric vertical tubes through which the steam passes, and long enough to ensure the complete immersion of the thermometer in the steam. From the boiling point thus obtained the atmospheric pressure may be found by reference to tables, and, given the atmospheric pressure, the height above sea level may be calculated. The alteration in boiling point is *roughly* 1° C. for every 300 yards of vertical height.

Hyssop (*Botany*). An aromatic shrubby plant, *Hyssopus officinalis* (order, *Labiatæ*), bearing blue flowers. The leaves and young plants are sometimes used in cookery and also in medicine.

Hysteresis (*Elect.*) The intensity of magnetisation produced in iron by a given magnetising force depends not only upon its state at the time, but on its previous magnetic treatment, for if iron be magnetised up to any point, and the magnetising force then removed, it still retains a certain amount of "residual magnetism," and it will require a certain reverse magnetising force to bring this to zero before it begins to become magnetised in the opposite direction. Professor Ewing has applied the term hysteresis to denote the general phenomena which arise from this tendency of iron to persist in its magnetic state. The practical result is that iron cannot be carried through "cycles" of magnetisation—as, for instance, by an alternating magnetic force—without loss of energy, which appears as heat in the iron. This loss is proportional to the frequency, but increases faster than the magnetic induction "B," being, according to Steinmetz, proportional to its 1·6th power. *See also* IRON LOSSES. To give some idea of its magnitude it may be stated that in good modern charcoal iron used for armature stampings, etc., it is roughly about 4,000 ergs per cubic centimetre per cycle, when maximum induction is $B = 10,000$. Another useful way of expressing the same loss is to say that it is from 2 to 3 watts per lb. at 100 cycles per second at the above induction. Although in many ways hysteresis suggests the idea of molecular friction, Professor Ewing has shown that such an assumption is unnecessary, and he considers the loss to be due to the oscillations of the iron particles as they settle down into new positions of equilibrium under the influence of the magnetising force.

I (*Chem.*) The symbol for IODINE (*q.v.*)

—— (*Elect.*) Used to denote the INTENSITY OF MAGNETISATION (*q.v.*)

—— (*Phys., Eng., etc.*) Used to denote the MOMENT OF INERTIA (*q.v.*); the letter K is also used for the same quantity.

Ice, Action of (*Geol.*) Considerable quantities of stony debris find their way on to the surface of a glacier, as well as into its lower parts. These are transported seaward from the mountain centres, and are left at the parts where the rate of onward flow of the ice is balanced by that of melting. Some erosion of the surface in contact with the moving ice is effected where suitable conditions obtain. Icebergs and floating ice in general also act as vehicles of transport for rocky debris.

Iceberg. A large mass of ice which has been broken from the end of a glacier where this has flowed out to the deeper part of the sea. Ice fractures readily when subjected to strain, and thus tidal movements suffice to break off bergs, which may float to great distances before being completely melted. It is generally considered that the mass of the submerged portion of a berg is about nine times that of the part above water.

Ice Calorimeter (*Phys.*) An arrangement in which the heat given out by a substance in cooling from some known temperature to 0° C. is measured in terms of the mass of ice melted by it. The original form was devised by Laplace and Lavoisier, although Black had previously employed the principle. Bunsen introduced a method of determining the amount of ice melted by means of its change of volume, and his instrument is especially useful when only small quantities of a substance are available.

Iceland Moss (*Botany*). *Cetraria islandica* (class, *Lichenes*). This lichen, a native of North Europe, is used for its nutritive and medicinal properties.

Iceland Spar (*Min.*) A transparent variety of Calcite, easily cleavable; it is the variety used in the making of polariscopes (*q.v.*), and is in great demand. There were at one time large deposits of it in Iceland. *See also* CALCITE.

Ichnography. (1) A ground plan, *e.g.* the ground plan or horizontal section of a building or part of a building. (2) A plan or map.

Iconography. The science or art that treats of ancient paintings, sculptures, mosaic work, engravings on gems or metals, and especially statues and busts. The *iconography* of an individual is a description of all known portraits of such individual.

Icosahedron. A solid having twenty equal plane faces; a regular icosahedron is contained by twenty equal equilateral triangles.

Ideal Gas (*Phys.*) A gas for which the law

$$\frac{\text{Pressure} \times \text{Volume}}{\text{Absolute Temperature}} = \text{Constant}$$

is exactly true.

Ideograph, Ideogram. A symbol or figure employed in some systems of writing to suggest or express an object: a hieroglyphic.

Idiograph. A private mark or signature: a trademark.

Idiomorphic Crystals (*Geol.*) It is necessary in many cases to mark the distinction between crystals which, on the one hand, have grown up and consolidated from a fluid magma in such a manner as to press upon the growing crystals next them and thus mutually prevent each other from assuming the bounding surface proper to each of them; and, on the other hand, those which have grown and consolidated in such a manner that they have been free to take their own proper shape. For the former case the term ALLOTRIOMORPHIC is used, while for the latter, in which the crystals have assumed their own normal shape, the term used is IDIOMORPHIC. The difference of comportment is connected with the conditions of pressure under which consolidation took place.

Idle *or* **Wattless Current** (*Elect. Eng.*) When the current and the electromotive force in a circuit differ in phase (*q.v.*), the product of the two is not equal to the power. *See* ELECTRICAL POWER. If the angle of lag be Cos ϕ, then the power in watts is EC Cos ϕ. The product C Cos ϕ may be regarded as the resolved part of the current, which is in the same phase as the electromotive force E, while the remaining component of the current C Sin ϕ, differs in phase from the E.M.F. by 90°. The product EC Sin $\phi = 0$, and C Sin ϕ may be called the IDLE CURRENT.

Idle Coil (*Elect. Eng.*) In certain forms of armature a coil may at a given instant have no induced electromotive force acting in it; it is then termed an IDLE COIL.

Idle Wheel *or* **Idler** (*Eng.*) A wheel in a train of gearing which rides loose on its shaft and does not affect the ratio of the velocities of the other wheels in the train.

Idocrase (*Min.*) A basic calcium aluminium silicate formula, possibly $H(OH)_2Ca_{12}.(Al,Fe)_6(SiO_4)_{10}$. Usually, if not always, it occurs as a mineral product arising from the thermo-metamorphism of calcareous rocks. Tetragonal, occurring in prisms, yellow to brown or black. Also called Vesuvianite. From Vesuvius, Norway, Siberia, the United States, etc.

Igniter. (1) A fuse or other appliance for firing a charge in blasting. (2) The ignition device in gas engines. *See* IGNITION.

Ignition (*Eng.*) In gas, petrol, and oil engines the charge is ignited or fired in various ways. (1) FLAME IGNITION is the oldest method. A small flame was allowed to come into contact with the compressed gases through a port; the chamber containing the flame was cut off from connection with the open air at the instant before the port leading into the cylinder was opened, thus preventing the charge from exploding directly into the atmosphere. Flame ignition is now obsolete. (2) In TUBE IGNITION the charge is put into direct communication with the inside of a short ignition tube of metal or porcelain; the tube is kept at a high temperature by a burner outside. After the explosion of the charge, communication between the cylinder and the ignition tube is cut off until ignition is again required. Tube ignition is now used in the majority of stationary gas and oil engines. (3) ELECTRIC IGNITION consists in the production of an electric spark inside the cylinder at the proper instant. The current is led in by a wire passing through an insulated porcelain plug, the SPARKING PLUG; the end of this wire terminates in a platinum point, which is placed very close to another similar point which is in electrical communication with the metal work of the engine, and therefore is electrically "connected to earth." The spark thus occurs between the end of the conducting wire, which is charged up to a high potential, and a point which is at zero potential. In order to provide the current, the wire is either connected to one terminal of a small INDUCTION COIL (*q.v.*) or else to a small magneto machine (*i.e.* a dynamo with permanent field magnets). If a coil is used, it is driven by a storage battery, usually of two cells, giving an E.M.F. of about four volts. The contact breaker of the coil is worked by the HALF SPEED SHAFT. *See* PETROL ENGINE. Electric ignition is universally used on motor cars, cycles, launches, etc., driven by petrol engines, and its use is becoming increasingly common in large gas engines, especially on the Continent. (4) In a few cases AUTOMATIC IGNITION is employed; the gas becomes sufficiently hot at the instant of greatest compression to ignite spontaneously.

Ignition Plug (*Motor Cars, etc.*) *See* SPARKING PLUG.

Ignition Valve (*Eng., etc.*) A small valve which is opened just before the explosion of the charge in a gas engine, in order to effect communication between the charge in cylinder and the heated ignition chamber.

I.H.P. (*Eng.*) *See* INDICATED HORSE POWER.

Ileum (*Zoology*). The portion of the small intestine following the duodenum. It is the seat of absorption of the chyme by the agency of the VILLI (*q.v.*)

Ilex (*Botany*). A genus of the order *Aquifoliaceæ*, occurring in many parts of the world. The holly is a well known plant of the genus, and *Ilex paraguensis* is the MATÉ or PARAGUAY TEA.

Ilium (*Zoology*). The bone of the hip girdle which articulates with the sacral vertebræ of the backbone. It forms the outer portion of the pelvis, on either side.

Illuminated Manuscripts. The art of illuminating manuscripts originated in the third century, and continued until the seventeenth, the monks being the most skilful exponents. The embellishments generally took the form of drawings, more particularly ornate initial letters, executed in body colours and gold. The earliest illuminations were done with red lead, later with cinnabar. Specimens of fourth and eighth century work are to be seen at the Vatican and the Louvre. Some of the finest examples were executed between the fifteenth and seventeenth centuries.

Illuminating Power (*Light*). The illuminating power or INTENSITY of a source of light is the ratio of the illumination thrown (normally) by it on any surface to the illumination thrown (normally) by a standard source, *e.g.* a STANDARD CANDLE (*q.v.*), on the same screen, both sources being equidistant from the screen. More briefly it is the ratio of the light emitted by the given source to the light emitted by a standard source.

Illumination, Artificial. *See* ARTIFICIAL ILLUMINATION.

Ilmenite (*Min.*) An iron and titanium oxide, $FeTiO_3$; the proportions of titanium and iron vary greatly, the one replacing the other. It is one of the ores of iron, and is a common original constituent of the basic eruptive rocks, in which it is one of the first minerals to consolidate. In composition it may be regarded as a ferrous titanate; but it has a wide range in composition, and it passes in one direction into Magnetite and in another into Hæmatite. It usually occurs in the form of thin crystalline plates in which the forms proper to the mineral are but rarely developed. It belongs to the Rhombohedral System of crystallisation. A second mode of occurrence is in connection with Quartz in the crystalline schists; while yet another is that sometimes known as ISERINE, which is slightly magnetic, and is the chief constituent of MAGNETIC SAND.

Image (*Phys.*) If light diverging from a point A is made by any means to converge to a second point B, then B is termed a REAL IMAGE of A; if the light diverging from A be caused to appear to diverge from another point C, then C is termed a VIRTUAL IMAGE of A. A real image may be received on a screen; a virtual image cannot.

Imbricated (*Architect.*) Formed with one part lapping over another, so as to resemble a tiled roof.

Imide (*Chem.*) A compound containing the group $>NH$, attached to an acid residue. Examples are Succinimide, Phthalimide (*q.v.*)

$$\begin{array}{l} CH_2COOH \\ | \\ CH_2COOH \end{array} \qquad \begin{array}{l} CH_2CO \\ | \\ CH_2CO \end{array}\!\!\!> NH$$

Succinic Acid. Succinimide.

$$C_6H_4 \begin{array}{l} <COOH \\ <COOH \end{array} \qquad C_6H_4 <\begin{array}{l} CO \\ CO \end{array}> NH$$

Phthalic Acid. Phthalimide.

Imitation (*Music*). The repetition of a musical figure by another part of the harmony either at the same or at a different pitch.

Imitation-Ivory. *See* CELLULOID *and* VEGETABLE IVORY.

Imitation Parchment. Ordinary paper passed through a bath of sulphuric acid, which has the peculiar effect of "toughening" the fibres. The acid is immediately washed out and the paper dried.

Immersion (*Astron.*) The disappearance of one heavenly body behind another or in the shadow of another.

Impact. A sudden blow: a collision between two bodies: the force or forces exerted by one body on another as the result of a collision.

Impale (*Her.*) Two coats of arms may be placed upon one shield side by side, separated palewise. A husband and wife may thus blazon their escutcheon, the arms of the husband always occupying the dexter half, those of the wife the sinister half of the shield. A bishop also impales the arms of his official see with his own arms.

Impaste, Impasto (*Paint., etc.*) To lay on colours thickly in order to create a bold effect. To mix lines and points on a plate in engraving in order to represent depth of colouring.

Impedance (*Elect.*) The apparent resistance of a circuit or part of circuit when traversed by an alternating or variable current; that is, the ratio of the impressed E.M.F. to current. For steady currents this ratio is merely the ohmic resistance, but for variable currents it depends also upon the rate of variation, the self induction, and the capacity of the circuit. In dealing with alternate currents it is often necessary to consider the impedance, which may differ considerably from the resistance. Let n be the frequency of the current, L the self induction (*q.v.*) of the circuit, and R its resistance. Then, if the capacity of the circuit be neligible, the impedance is equal to

$$\sqrt{R^2 + 4\pi^2 n^2 L^2} = \sqrt{R^2 + p^2 L^2}$$

where $p = 2\pi n$. If nL be large compared with R, the impedance reduces to pL; while if R be large compared with nL the impedance is practically equal to the resistance R.

Impedance Coil (*Elect. Eng.*) A CHOKING COIL (*q.v.*)

Imperfect (*Music*). Used in connection with (1) Cadence, (2) Interval, both of which see.

Imperfect Cadence (*Music*). *See* CADENCE.

Imperial (*Paper Manufac.*) (1) Writing paper of a size 34 by 22 in. (2) Printing paper, size 30 by 22 in.

Imperial Red (*Dec.*) A bright red similar in composition to Royal Red (*q.v.*)

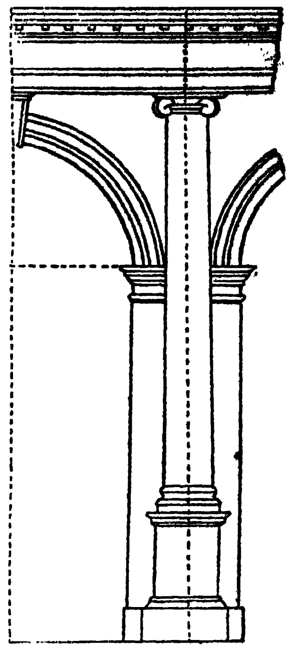
Imperials (*Build.*) Slates measuring 30 by 24 in.

Impetuoso (*Music*). Impetuously.

Imposing Stone (*Typog.*) A smooth stone or metal surface on which pages or columns of type are imposed or made into formes, and on which formes are laid for correction.

Imposition (*Typog.*) The arrangement of pages for printing, so that when the sheet is folded they may fall into proper numerical order.

Impost (*Architect.*) The horizontal mouldings crowning a pier, pilaster, or corbel, and from which an arch springs. Each order has its distinctive impost; occasionally the impost is formed of the entablature of the order.



IMPOST.

Impregnation (*Timber*). Soaking timber with a fluid in order to prevent rot; Burnett's fluid, creosote, etc., are employed.

Impression. (1) The act of impressing. (2) A copy taken by pressure from an engraved plate, type, etc. (3) The total number of copies printed at one time: an edition.

Impressionism (*Paint.*) A method of painting which aims at giving the general tone and salient features of a subject, *e.g.* the broad impression produced by some aspect of nature at first sight, excluding minute details and elaborate finish.

Imprint (*Print.*) The name of the printer or publisher (with date and place of publication) affixed to a book, magazine, newspaper, etc.

Impromptu (*Music*). A composition of an *extempore* character.

Impulse. A suddenly applied force; in engineering the term is applied especially to the force of the explosion in a gas or oil engine.

Impurities of Air. *See* ATMOSPHERE.

In (*Chem.*) The symbol for INDIUM (*q.v.*)

In Antis (*Architect.*) *See* ANTIS.

Incandescence. Glowing; self-luminous (emitting light), owing to high temperature.

Incandescent Electric Lamp. Consists essentially of a carbon filament of high resistance enclosed in a vacuum, and heated to whiteness by an electric current. *See also* ELECTRIC LIGHTING.

Incandescent Gaslight. The production of light by means of a hot, non-luminous gas flame, which impinges on a MANTLE (*q.v.*) and raises it to a high temperature, so that it becomes incandescent.

Incandescent Mantle. *See* MANTLE, INCANDESCENT.

Incandescent Tube Ignition (*Eng., etc.*) The ignition of the charge in the cylinder of a gas or petrol engine by means of a hot tube. *See* IGNITION.

Inch. *See* WEIGHTS AND MEASURES.

Inches of Rain (*Meteorol.*) *See* RAINFALL.

Inch Pound, Inch Ton (*Eng., etc.*) Units of work occasionally used; the work done when 1 lb. and 1 ton respectively are raised 1 in.

Incident Ray (*Light*). A ray which falls on the surface of a reflecting or refracting medium, but is itself wholly outside that medium.

Incisors (*Zoology*). The sharp cutting teeth in the front of the upper and lower jaws.

Inclination, Angle of (*Elect.*) The angle between the actual direction of the Earth's magnetic field at a given place and its projection on a horizontal plane. In London its value is at present about 67°.

Incline (*Mining*). A sloping shaft.

Inclined Plane. In mechanics one of the elementary types of machine, often called the mechanical powers. A gradient (*q.v.*) on a railway, or a wedge may be taken as an example.

Inclines on Railways. *See* GRADIENTS.

Incrustation (*Eng.*) The solid coating of salts from hard water, which forms on the inside of the plates of a boiler.

Incubation (*Hygiene*). The incubation period or time of development of a disease is that which elapses between actual infection and the appearance of the first signs or symptoms. Little is known of the changes which take place during this period, beyond the fact that the poison is multiplying in some part of the system.

Incunabulum, *pl.* **Incunabula** (*Print.*) A term applied to a book or books produced during the earliest period of the art of printing, more especially those printed before the beginning of the sixteenth century (1500).

Incuse (*Coins*) An impression hammered or impressed *in intaglio* on a coin.

Indamines (*Chem.*) Derivatives of Quinone di-imide. They are weak bases which form green or blue salts with acids. They are unstable; an excess of acid decomposes them into quinone and the base from which they were formed. They are important as being intermediate products in the formation of some important classes of dyes. *Cf.* METHYLENE BLUE *and* SAFFRANINE. INDAMINE or PHENYLENE BLUE, $HN:C_6H_4:NC_6H_4NH_2$, is formed by oxidation of a mixture of paraphenylene diamine and aniline. On reduction it yields paradiamide odiphenylamine, which is therefore the leuco-compound. *See* LEUCO-COMPOUNDS.

$$\left.\begin{array}{r} HN:C_6H_4 \\ H_2N.C_6H_4 \end{array}\right\rangle N + 2H = \left.\begin{array}{r} H_2N.C_6H_4 \\ H_2N.C_6H_4 \end{array}\right\rangle NH$$

Bindschedler's green and toluylene blue indamines of the formulæ

$$\left.\begin{array}{r} (CH_3)_2N\text{——}C_6H_4 \\ (CH_3)_2NCl = C_6H_4 \end{array}\right\rangle N \text{ and } \left.\begin{array}{r} (H_2N)_2.C_7H_5 \\ (CH_3)_2NCl = C_6H_4 \end{array}\right\rangle N$$

respectively.

Indanthrene. *See* DYES AND DYEING.

Indehiscent (*Botany*). A term applied to a fruit which does not open to set free the seeds (*e.g.* hazel nut, plum, etc.)

Indent (*Typog.*) A line commenced a little farther in from the margin, *e.g.* the commencement of a paragraph.

Indented (*Her.*) One of the forms given to partition lines. *See under* HERALDRY.

Indestructibility of Matter (*Chem.*) Matter can neither be created nor destroyed. Whatever changes it may undergo, whether physical or chemical, its actual mass remains unaltered, and can in general be measured by suitable experiments, and shown (within the necessary limits of experimental error) to be equal to its original mass.

Index. That which points out something. In mathematics the quantity denoting the power to which another quantity is to be raised.

—— (*Eng.*) A pointer or indicator on a gauge of any kind.

—— (*Min.*) The index of a crystal face is the reciprocal of the INTERCEPTS (*q.v.*) of that face. The index is always expressed as a whole number. Hence if the intercepts are 2 : 4 : 1, the index is written 214, instead of $\frac{2}{4}\,\frac{1}{4}\,\frac{4}{4}$ or $\frac{1}{2}\,\frac{1}{4}\,\frac{1}{1}$. When the different faces of one form are to be designated, trigonometrical sign is taken into account.

—— (*Typog.*) (1) The sign of a hand with the forefinger pointing. (2) The references, or alphabetical table of contents, generally placed at the end of a book.

—— (*Watches*). The regulator of a watch. It has two pins embracing the outer coil of the balance spring, enabling the wearer to alter the acting length of the spring. *See* BALANCE SPRING, FREE SPRING.

Index of Refraction (*Phys.*) When light passes from one transparent body to another, the ratio of the sines of the angles of incidence and refraction is a constant for the two given substances for the same wave length, and is known as the RELATIVE INDEX OF REFRACTION between the two substances, the ABSOLUTE INDEX for either of them being the value of the same ratio when light passes from a vacuum into the substance. According to the wave theory, the relative index is really the ratio of the light velocities in the two substances, and consequently it has a different value for each wave length.

Indian Hemp. *Cannabis sativa* (order, *Moraceæ*). The "Cannabis Indica" of commerce consists of the dried tops of the hemp plant, including flowers, fruit, and the exuded resin. A mixture of leaves and fruit is known as Bhang or Hashish. The resin is valued for its narcotic property.

Indian Ink. A black ink sold in sticks, and made from fine lampblack mixed with a binding material, such as parchment size or fish glue, and a little musk, camphor, and other perfume. The lampblack is exceedingly fine, and is derived from the burning of certain oils, camphor, and camphor wood. The ink is carefully dried and made into sticks, which are polished and gilded partially or wholly. Genuine Indian ink comes from China. Various attempts have been made to manufacture it in France and elsewhere, but without much success. The best varieties, when broken, show a bright jet black fracture, not unlike the fracture of genuine liquorice The perfume is to some extent an indication of the quality.

Indian Lake (*Dec.*) A lake obtained from the secretions of *Coccus Lacca*. It is now used to only a small extent, being superseded by madder. It is somewhat fugitive, but not to the extent of crimson and other lakes made from cochineal.

Indian Red (*Dec.*) A useful pigment of a dark red colour, having a slightly purplish hue, and used by the painter principally for staining or colouring. Genuine Indian red is a natural product found in India, but most of the pigment sold is artificially

prepared by the calcination of ochre and ferrous sulphate. It has no definite chemical composition. Genuine India red contains about 75 per cent. of ferric oxide. The pigment is one of the most permanent known, and it may be mixed with any other pigments without risk of producing a chemical change in them.

Indian Yellow (*Dec.*) A pigment obtained from the urine of Indian cows which have been fed on mango leaves. It is fairly permanent as a water colour, and may be used ground in oil, poppy oil being best for the purpose. It is gradually going out of use.

Indiarubber. *See* RUBBER.

Indican (*Chem.*) *See* INDIGO. This name is also applied by physiologists to potassium indoxyl sulphate. *See* INDOXYL.

Indicated Horse Power *or* **I.H.P.** (*Eng.*) Indicated horse power, *i.e.* the actual work performed by the steam (or gas) in the cylinder, as calculated from the INDICATOR DIAGRAM (*q.v.*)

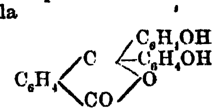
Indicating (*Eng.*) Taking an INDICATOR DIAGRAM of an engine. *See* INDICATORS *and* INDICATOR DIAGRAMS.

Indicator (*Cotton Spinning*). An instrument fixed on spinning machinery for registering the quantity of work produced.

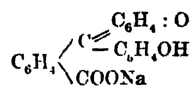
Indicator Card (*Eng.*) The card on which an INDICATOR DIAGRAM is drawn, or the diagram itself. *See* INDICATORS (*Eng.*)

Indicator Dial (*Clocks*). The "journeyman" clock, consisting only of a dial and handwork, with electrical fittings. It is under the control of, and actuated by, the "master" clock of an electric time circuit. *See* MASTER CLOCK.

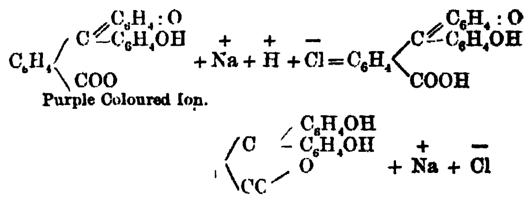
Indicators (*Chem.*) Substances used in volumetric analysis to indicate the completion of a reaction. Suppose hydrochloric acid of known strength is being added from a burette to a solution of caustic soda in order to exactly neutralise the latter and then to calculate its strength, it cannot be told by inspection when the change is completed. To enable one to judge when the reaction is completed, a substance is added which gives one colour with an alkali and another colour with an acid; the substance added is called an indicator. A good indicator must give a distinct colour change, and it must be sensitive; that is, a minute quantity of it must be sufficient for the purpose, for the change in the indicator is brought about by a reaction between it and one or other of the solutions under examination, so that the amount of the latter required to produce the change in the indicator must be negligible. In volumetric analysis indicators are used in the form of solutions of such strength that only a few drops of the indicator solution are required. INDICATORS USED FOR ACIDS AND ALKALIS:—(1) *Iodeosin* (*Erythrosin*): With acids orange, with alkalis cherry red; used in presence of ether in titrating dilute solution of acids and alkalis; can be used for $\frac{1}{10}$ or even $\frac{1}{100}$ normal solutions. (2) *Methyl Orange*: With acids pink, with alkalis yellow; unaffected by carbon dioxide. (3) *Congo Red*: With acids blue, with alkalis red. (4) *Lacmoid*: Red with acids, blue with alkalis. (5) *Litmus*: Red with acids, blue with alkalis, violet when neutral; it is affected by carbon dioxide, so that when used in titrating a carbonate the liquid must be boiled to expel carbon dioxide. (6) *Turmeric*: Yellow with acids, brown with alkalis. Its behaviour with boric acid is characteristic; when turmeric paper is dipped in boric acid solution and then dried, it is coloured reddish brown, and this colour is not changed to yellow again by hydrochloric acid. (7) *Phenolphthalein*: Colourless with acids, purple with alkalis; cannot be used for ammonia. The first four are more sensitive towards alkalis than towards acids; the others are more sensitive towards acids than towards alkalis. We will illustrate the theory of the action of indicators by an example from each class. Methyl orange has the formula $(CH_3)_2\overset{*}{N} . C_6H_4 . N : N . C_6H_4SO_2ONa$. Its action as an indicator depends on the basic properties of the nitrogen atom marked with an asterisk; for shortness we will write the formula BN. With an acid (say HCl) a salt, BN . HCl, is formed, and this in an aqueous solution is ionised thus, $BNHCl = \overset{+}{BNH} + \overset{-}{Cl}$. The positive ion $\overset{+}{BNH}$ is pink in dilute solution. On addition of an alkali (say NaOH) we have the reaction $\overset{+}{BNH} + \overset{-}{Cl} + \overset{+}{Na} + \overset{-}{OH} = BN + H_2O + \overset{+}{Na} + \overset{-}{Cl}$; that is, the methyl orange is reproduced and the pink colour changes to yellow, the colour of methyl orange in dilute aqueous solution. Phenolphthalein has the formula



Its action as an indicator depends on the fact that the substance itself is colourless in aqueous or acid solutions, while its salts have the quinoxoid structure



and are strongly coloured. The change from purple to colourless may be expressed by an equation thus:



Purple Coloured Ion.

INDICATORS USED IN OTHER VOLUMETRIC PROCESSES: Weak starch paste is used to indicate the presence of iodine, with which it forms a deep blue colour. Potassium chromate is used in the titration of neutral solutions of chlorides, bromides, and iodides by silver nitrate solution. To the chloride solution a little of the chromate is added, then the silver nitrate is run in. So long as a trace of chloride, etc., remains in solution no silver chromate can be formed and remain in the liquid. As soon as the chloride, etc., is all decomposed, silver chromate is formed and easily recognised by its dark red brown colour. Potassium ferricyanide is used in titrating a ferrous salt by potassium dichromate; this is an example of an *external* indicator. In this case the indicator is placed in drops on a white tile, and a

drop of the liquid being titrated is added to the indicator. So long as ferrous salt remains, a deep blue colour is produced. Many other indicators are used, but less commonly than the above. Many of the above indicators are used in special cases in the form of papers; unsized paper is dipped in a solution of the indicator and then dried. The ordinary litmus and turmeric papers are familiar instances. Some of these papers are wonderfully delicate tests for acid or alkaline reaction; *e.g.* azolithmin paper (*see* LITMUS) will show an alkaline reaction with solutions of caustic soda or ammonia of strengths little over $\frac{1}{5000}$ normal and $\frac{1}{1000}$ normal respectively.—W. H. H.

Indicators *and* **Indicator Diagrams** (*Eng.*) An INDICATOR DIAGRAM is a figure showing the relations between the pressure and volume of the WORKING SUBSTANCE (gas or steam, etc.) in the cylinder of an engine. It may be drawn from purely theoretical assumptions, as in the case of the diagram representing CARNOT'S CYCLE (fig. 1). In this case the working substance is originally at a pressure P_1 and a volume V_1. In the first operation it is compressed adiabatically to a volume V_2, the pressure meanwhile rising to P_2. The work done *on* the substance in this operation is represented by the area of the figure $P_1P_2V_2V_1$. It is then allowed to expand isothermally to a volume V_3, the pressure falling to P_3, and the work done *by* the substance is represented by $P_2P_3V_3V_2$. In the third operation it expands adiabatically to a volume V_4 and pressure P_4, the work done *by* it being represented by the area $P_3P_4V_4V_3$. It is finally compressed to its original pressure and volume, the work done *on* the substance being given by the area $P_4P_1V_1V_4$. The net work done by the substance during these four operations is given by the difference of the areas $P_2P_3P_4V_4V_2$ and $P_4P_1P_2V_2V_4$; that is, the area of the curved part of the figure, $P_1P_2P_3P_4$. This cycle of operations is purely theoretical, and has never been realised in practice. A theoretical representation of the changes in pressure of the steam in the cylinder of a steam engine may be arrived at as follows: Let A (fig. 2) be a cylinder with a piston B, and two pipes or ports C and D, each fitted with a tap or valve which can be opened or closed as required, C being the INLET or STEAM PORT, by which steam can be admitted, and D the OUTLET or EXHAUST PORT, by which the steam can escape. Let B be at the beginning of its stroke, so that the volume of the space between the piston and the end of the cylinder is very small, and let the pressure of any steam or other gases in the space be P_0. If at this instant D be open to the air, then P_0 will equal the pressure of the atmosphere. Close D and open C. The pressure inside will instantly rise to that of the steam; let this be P_1, represented by the point P_1 on the diagram. The piston will now begin to move, and if steam continue to enter the cylinder the pressure will remain at P_1. When the piston has advanced to E, let C be closed and the supply of steam be consequently cut off. The piston will still continue to move, being driven by the pressure of steam behind it; but this will no longer be P_1, but will gradually fall as its volume increases, in a manner indicated by the line P_1P_2 on the diagram, which is approximately a hyperbola. When the piston reaches F, let D be again opened; the pressure will drop to P_0, and if the return stroke now commences, steam will escape from D at this pressure, or very nearly so. The Indicator Diagram will have the form shown by the lower part of the figure, and if we calculate the average height of this figure $P_0P_1P_1P_2P_0$, we can find the average pressure of the steam during the stroke. To find the average height, we measure the total area of the diagram either by dividing it up into strips and applying SIMPSON'S RULE (*q.v.*) or by using the PLANIMETER (*q.v.*) Suppose the area to be a square inches, then if l be the length P_0P_0 in inches and x the average height, which we wish to find, we have $xl = a$ and $x = \frac{l}{a}$. We know the original pressure of the steam, and therefore know how many pounds pressure are represented by the line P_0P_1, and by proportion we can find the average pressure represented by x. The total amount of work done on the piston during one stroke of the engine is then found as follows: Let a be the area of the piston in square inches, p the average pressure during the stroke, l the length of stroke in feet; then pal is the work (in foot pounds) done in one stroke or half a revolution. If the steam act on both sides of the piston, the work in one revolution is $2pal$, and if n be the number of revolutions per minute, the total work done on the piston per minute is $2npal$ foot pounds or $\frac{2npal}{33,000}$ horse power. This is termed the INDICATED HORSE POWER (I.H.P.) of the engine.

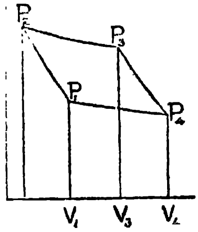


FIG. 1.

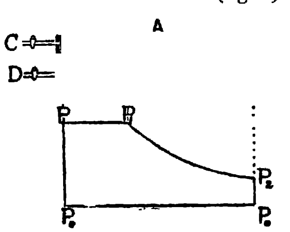

FIG. 2.

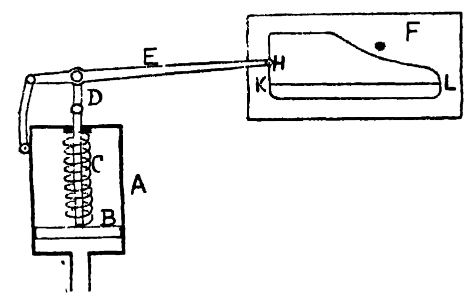

FIG. 3.

AN INDICATOR is an instrument for actually drawing the indicator diagram by the action of the steam itself. A small cylinder A (fig. 3) communicates directly with one end of the cylinder of the engine by a tube at the bottom. A piston B fits smoothly in A, and is pressed down by a spring C, whose strength is so adjusted that the piston will rise a convenient distance when the maximum steam pressure is exerted on B. The motion of B is communicated by a piston rod and link at D to a lever E, which carries a pencil at H. The pencil marks its position at each instant on a card F, which moves backward and forward at

the same rate as the piston of the engine. If F be stationary, H will describe a vertical line, the line of no volume, and the position of H shows the pressure of the steam at the instant; while if B be at rest (*i.e.* the inlet be cut off from connection with the cylinder by a tap), then if F move backward and forward, we shall obtain a horizontal line KL, the line of zero or atmospheric pressure. If both F and B move, the pencil will trace out a closed figure, which shows the relation of the pressure and volume of the steam at each instant of the stroke. This figure is the actual INDICATOR DIAGRAM for the engine; it will differ from the theoretical form shown in fig. 2, usually being more irregular in outline and having rounded corners. Thus in fig. 4 the piston of the engine begins to move before the steam in the cylinder has reached its full value, causing the corner B to be rounded off; then the steam is admitted at full pressure, giving the line BC, which is nearly horizontal; then the cut-off occurs and expansion begins. If the admission port were closed instantaneously, the corner C would be quite sharp, but in practice this is never the case. Expansion goes on during the remainder of the stroke till the exhaust port opens, and the pressure falls from D to E; the return stroke now occurs, and steam escapes from the cylinder at nearly constant pressure (shown by the line EA). If the exhaust port be closed slightly before the end of the stroke, the pressure of the remaining steam rises, through compression, producing what is termed CUSHIONING, which is shown by the rounding off of the corner A. If the cut-off occur earlier in the stroke, the diagram takes the form shown in fig. 5. If the engine be fitted with a condenser, the pressure of the steam falls to a value less than the atmospheric pressure, and the diagram extends below the ATMOSPHERIC LINE KL (fig. 3), which is drawn when the piston of the indicator remains at rest, while the card F moves in unison with the piston of the engine. A somewhat different form of indicator is used for gas engines, or in any engine where the changes of pressure are very rapid; but the essential principle is the same. The diagram for a typical gas engine using the Otto Cycle (*see* GAS ENGINES) is given here for completeness (fig. 6). The line AB is marked out while the charge is being drawn into the cylinder. The admission valve then closes, and the charge is compressed, giving the line BC (the COMPRESSION LINE). Explosion occurs and the pressure rises, giving the line CD. If combustion were complete before the piston began to move, this line would be vertical. At D the expansion of the exploded gases sets in, and the line DE (the EXPANSION LINE) shows the pressure during the forward stroke. At E the exhaust valve or port opens, and during the next return stroke the exhaust or burnt gases are expelled, the pressure again falling to the valve at A, and the cycle is complete. The area of the shaded portion is proportional to the work done in one cycle (two revolutions), and the average pressure is, as before, the average height of this portion.

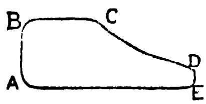

FIG. 4.

FIG.

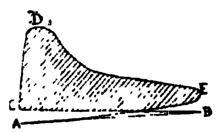

FIG.

Indifferent Equilibrium. A body is in indifferent equilibrium if on receiving a small displacement it does not experience any force tending either to increase or decrease the displacement.

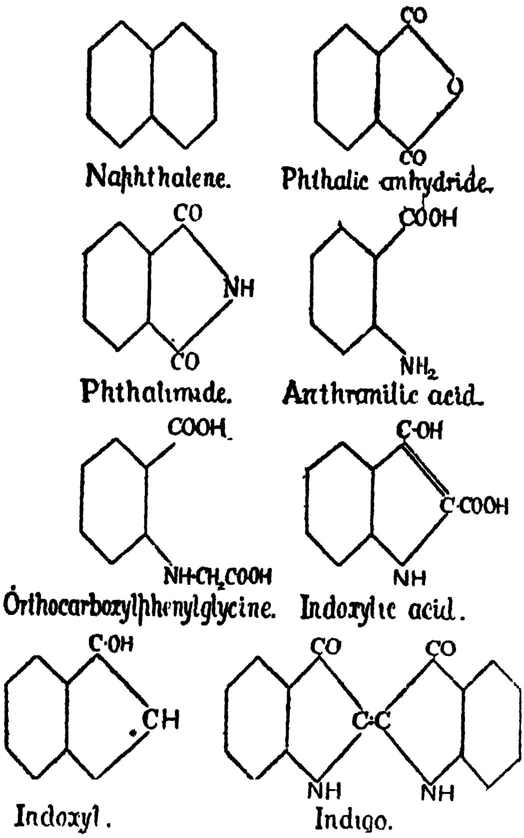
Indigo (*Chem.*) $C_6H_4 \left< {CO \atop NH} \right> C : C \left< {CO \atop NH} \right> C_6H_4$

A dark blue solid which exhibits a coppery lustre when rubbed; insoluble in water, alcohol, ether; soluble in hot aniline, in hot naphthalene, and in melted paraffin. It can be crystallised from the former. On heating, it sublimes, forming lustrous coppery prisms. Its vapour has a density corresponding to the above formula. Alkaline reducing agents dissolve indigo, forming INDIGO WHITE,

$$C_6H_4 \left< {C.OH \atop NH} \right> C - C \left< {C.OH \atop NH} \right> C_6H_4.$$

This property is used in dyeing cotton, the reducing agents employed being very various; *e.g.* lime and zinc dust, alkaline hyposulphite (*q.v.*), electrolytic reduction. Indigo white is a white crystalline solid, soluble in alcohol. When cotton is dipped in the alkaline solution and then exposed to air, the oxygen soon oxidises the indigo white to indigo again, and the blue so obtained is "fast." With sulphuric acid indigo forms, according to the strength of acid employed, mono-, di-, and trisulphonic acids. The disulphonic acid is soluble in water, and is used in wool dyeing; its sodium salt comes into trade as a paste under the name indigo carmine. On oxidation with nitric acid or chlorine water, indigo yields ISATIN (*q.v.*); on distillation with caustic potash it yields ANILINE (*q.v.*) Indigo is obtained to a very small extent from woad (*Isatis tinctoria*); to a much larger extent in India and South America from the leaves of the indigo plant (*Indigofera tinctoria*). These plants contain a glucoside indican. When the leaves of the Indian plant are soaked in water the glucoside yields a sugar and a substance INDOXYL (*q.v.*), which on oxidation yields indigo. The natural indigo is not a pure substance; it contains indigo red, indigo brown, and indigo gelatine. Pure indigo may be obtained from it by sublimation, or by crystallisation from aniline, or by conversion into indigo white and allowing the alkaline solution of the indigo white to oxidise in the air. The pure indigo is called INDIGOTIN. Large quantities of indigo are now made synthetically by the Baden Aniline & Soda Company. To give some idea of the scale on which artificial indigo is made, the export of indigo from the provinces of Calcutta and Madras fell in value by 43 per cent. between the years 1895-6 and 1899-1900; also in 1900 the above company were converting yearly 2,000,000 kilos of glacial acetic acid into monochloracetic acid in the manufacture of artificial indigo. A further impetus was given to the manufacture in 1901 by the Prussian Army order that all the blue military uniforms must be dyed by artificial indigo. The synthesis employed is Heumann's. Naphthalene, the most abundant and cheapest coal tar product, is converted into phthalic anhydride by fuming sulphuric acid and mercuric sulphate. The anhydride yields phthalimide with ammonia, and bromine and alkali convert the phthalimide to anthranilic acid. The latter with monochloracetic acid yields orthocarboxyphenyl-

glycine, which on fusion with alkali and action of air yields indoxyl and then indigo.



Many other syntheses of indigo are known. *See also* DYES AND DYEING.—W. H. H.

Indigo (*Dec.*) A dark blue produced from a number of different plants, including *Indigofera tinctoria* and *Indigofera anil* (order, *Leguminosæ*). It is a useful blue for the house painter, although it cannot be mixed with lead or lead chromates. Artificial indigo is now an established commercial success, and bids fair to drive the natural article from the market. For painting purposes indigo may be employed for producing effects difficult to obtain in any other way.

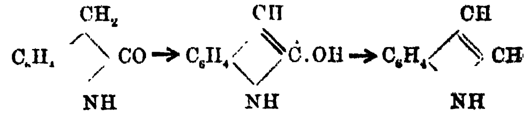
Indigotin (*Chem.*) *See* INDIGO.

Indigo White (*Chem.*) *See* INDIGO.

Indium, In. (*Chem.*) Atomic weight, 114. A soft white metal; melts at 176°; on heating strongly it burns with a violet flame; it dissolves in dilute acids, forming indium salts; its salts when acted on in solution by zinc or cadmium deposit indium. Forms three chlorides, InCl, $InCl_2$, $InCl_3$. The first two are decomposed by water, giving the metal and $InCl_3$. The metal belongs to the same group as aluminium. It occurs to a minute amount in zinc blende, in which it was discovered by the spectroscope; its spectrum contains two bright blue lines.

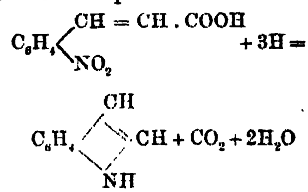
Indogen (*Chem.*) *See* INDOXYL.

Indole (*Chem.*), 
Crystallises in shining petals; melts at 52°; peculiar and rather disagreeable smell; volatile in steam; soluble in hot water, in alcohol, ether, and benzene. It is a weak base. It is a pyrrol derivative. Indole is formed by putrefactive changes in the intestines; also when albumins are melted with caustic potash. Formed: (1) By reduction of oxindole with zinc and hydrochloric acid—



Tautomeric Forms.

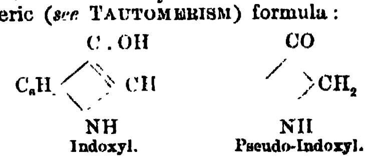
(2) By reduction of orthonitrocinnamic acid with zinc dust and caustic potash—



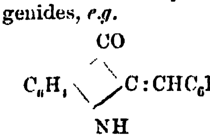
It was first obtained by reduction of indigo. On oxidation with ozone it again passes into indigo. *See also* SKATOLE.

Indoxyl (*Chem.*), 
(β-oxyindole).

An unstable oil which dissolves in water with yellow fluorescence. In alkaline solution it is easily oxidised by air to indigo. With potassium pyrosulphate it forms potassium indoxyl sulphate, $SO_2<^{OK}_{C_8H_6NO}$, a substance which occurs in urine; it arises from indole which is formed in the intestines. Indoxyl is an intermediate product in the synthesis of indigo (*q.v.*) It is formed from indigo by melting with caustic potash out of contact with air. In some of its reactions indoxyl behaves as if it had the tautomeric (*see* TAUTOMERISM) formula:



Thus with aldehydes and ketones it yields Indogenides, *e.g.*



Benzaldehyde indogenide.

Indogen is the name given to the group 
Induced Current (*Elect.*) The current produced in a conducting circuit when the number of magnetic

lines of force passing through it is varied. *See* INDUCTION.

Induced Magnetism. The magnetism produced in a piece of iron (or steel) which was previously unmagnetised, by placing it in a magnetic field.

Inductance (*Elect. Eng.*) (1) In general terms, equivalent to INDUCTION (*q.v.*) (2) The COEFFICIENT OF SELF INDUCTION of any circuit. *See* SELF INDUCTION.

Induction Coil (*Elect.*) An apparatus for obtaining a very small current at a very high voltage from a battery current of low voltage, and hence really a transformer especially adapted to work with a continuous current from a few cells. It consists essentially of an iron core, usually of wire, wound with two independent windings, the first or PRIMARY being merely two or three layers of stout wire. This is connected to the battery through a "contact breaker," the result being to magnetise and demagnetise the core at a rate determined by the stiffness of the contact breaker spring. The lines of force thus produced cut the SECONDARY coil, wound over the primary, setting up in it an induced E.M.F. whose magnitude depends only upon the number of lines of force, the number of turns, and the rate at which the lines cut the turns, and thus may be made great enough to produce sparks of considerable length by sufficiently increasing the number of secondary turns. The greatest care is necessary in insulating the secondary from the primary, and also the various turns of the secondary from each other, and large coils usually have the secondary built up of numerous independent small coils wound in thin vertical slices separated by discs of insulating material.

Induction, Electro-Magnetic. When a conductor is moved at right angles to the lines of force in a magnetic field (*i.e.* when there is relative motion), an electromotive force is set up in it which is independent of its material, and, except indirectly, of its size and shape also; it depends only upon the number of lines of force cut and the time in which they are cut. In other words, the rate of cutting is a measure of the E.M.F. If the conductor and the field are not at right angles, only the resolved component of the motion which is at right angles to the lines of force is effective, no E.M.F. being produced by the component of the motion along the lines of force. The fact that an induced E.M.F. is independent of material is the basis of the definition of unit E.M.F., which is naturally defined as being the E.M.F. produced in a conductor cutting one line of force per second. It should be noticed that the induced current cannot be so simply stated; it may not even exist, and in any case its magnitude depends upon the resistance of the conductor and of the rest of the circuit. *See also* INDUCTION (SELF, MUTUAL, MAGNETIC, *etc.*)

——, Electrostatic. When a neutral body becomes electrified by mere proximity to a charged body without actually receiving any of its charge, it is said to be charged by induction. Another way of expressing the same fact is to say that if lines of electric force pass in or out of a conductor, they end and begin in electric charges, and hence a conductor necessarily becomes charged when placed in an electrostatic field of force.

——, Magnetic. If a piece of iron, steel, etc., previously unmagnetised, be placed in a magnetic fluid, it becomes a magnet. It is then said to be magnetised by induction. *See* MAGNETIC INDUCTION.

Induction, Mutual (*Elect.*) When a current is started or stopped, or varied in strength in one circuit, it will produce an induced E.M.F. in a neighbouring and independent circuit, because some of the lines of force produced in the first circuit cut the second.

——, Self (*Elect.*) When a current flows in a circuit, a magnetic field of greater or less strength is always produced, and this field, while appearing or disappearing, necessarily cuts the circuit itself, and in so doing sets up an induced E.M.F. With steady currents this effect only occurs at its starting or stopping, the result being that the rise of a current is opposed by the self-induced E.M.F. in the opposite direction, and its stoppage also opposed by another self-induced E.M.F. in the same direction, the effects being most conspicuous in the case of coils of wire having iron cores. The result is that an electric current behaves as if it possessed inertia, and is unable to start or stop instantaneously.

——, Self, Coefficient of (*Elect.*) This may be defined for any circuit or part of a circuit as being numerically equal to the "amount of cutting" which takes place when unit current is stopped or started in that circuit. For instance, if unit current produces l lines of force, and these lines cut n turns in appearing or disappearing, then $l \times n$ is the "amount of cutting," and is the coefficient of self induction. This is the absolute unit, the practical unit being the HENRY, which is 10^9 absolute units. It is usually denoted by the letter L.

Induction Valve, Port, etc. (*Eng.*) The valve or port by which steam (or gas) enters the cylinder of an engine: more usually termed an ADMISSION VALVE or PORT.

Inductive Capacity, Specific (*Elect.*) *See* SPECIFIC INDUCTIVE CAPACITY.

Inductor Alternator (*Elect. Eng.*) An alternating current dynamo in which the change of flux through the armature coils is produced by the motion of masses of soft iron, both field magnets and armature coils remaining at rest. *See* DYNAMO.

Indulines (*Chem.*) Dyes ranging in shade from red to dark blue. They are insoluble in water, but soluble in alcohol. They are divided into classes as follows:

Benzene induline, $HN : C_6H_3 \genfrac{<}{>}{0pt}{}{N}{N} C_6H_4.$

Isorosinduline, $HN : C_6H_3 \genfrac{<}{>}{0pt}{}{N}{\underset{C_6H_5}{N}} C_{10}H_6.$

Rosinduline, $HN : C_{10}H_5 \genfrac{<}{>}{0pt}{}{N}{\underset{C_6H_5}{N}} C_6H_4.$

Naphthinduline, $HN : C\ H \genfrac{<}{>}{0pt}{}{N}{N} C_{10}H_6.$

From these many derivatives are obtained by introducing other radicals in place of hydrogen in the HN, and benzene and naphthalene residues on the left and right of the formulæ. The preparation of the simpler indulines consists in heating together a mixture of amidoazobenzene, aniline, and aniline hydrochloride. Rosinduline is prepared by heating benzene-azo-α-naphthylamine with aniline and aniline hydrochloride.

Industrial Soaps. A term used to describe that class of soap used for special purposes, such as ox gall soap, which is useful for scouring woollen goods and cleaning carpets, soap for silk dyers, fulling soap, etc.

Inequalities, Secular (*Astron.*) Perturbations of the celestial bodies so small that they only become important in a long period of time.

Inertia. The property of matter whereby it resists the action of a force which tends to change its state of rest or of uniform motion in a straight line.

——, Moment of. A quantity which takes the place of mass in the mechanics of rotating bodies. It is obtained by multiplying the mass of each particle in the rotating body by the square of its distance from the axis of rotation, and summing the series to an infinite number of terms. It can be shown that the ordinary equations of linear motion are true for rotatory motions if moment of inertia be written in place of mass, and angular velocity in place of linear velocity; for instance, the energy of a rotating body is $\frac{1}{2} I\omega^2$, where I = moment of inertia and ω = angular velocity. The moment of inertia of a body is often written in the form $I = Mk^2$, where M is its mass and k the radius of gyration; *i.e.* that distance from the axis of rotation at which all the mass must be placed in order that its kinetic energy may be unaltered.

Inescutcheon *or* **Shield of Pretence** (*Her.*) A small shield placed on an escutcheon. The arms of Ulster are placed in this manner on the shields of baronets.

Infection. *See* CONTAGION.

Infectious Diseases (*Hygiene*). *See* DANGEROUS INFECTIOUS DISEASES.

Inferior Conjunction (*Astron.*) Two or more bodies are said to be in conjunction when they are in the same longitude or right ascension. They are in inferior conjunction when they are on the same side of the sun.

Inferior Figures *or* **Letters** (*Typog.*) Small letters or figures which range at the bottom of an ordinary letter or figure, thus: $_2$, $_3$, $_1$. The reverse of "superior."

Inferior Planets (*Astron.*) Those whose orbits lie between that of the earth and the sun, *i.e.* Mercury and Venus (*q.v.*)

Infiltration (*Geol.*) A mode of action connected with the tendency of fluids to spread to wider areas under the combined influence of surface tension and gravitation. Water containing any one of various substances in solution may thus carry them into various parts of the Earth's crust below and around their starting point, and may eventually leave these substances in new positions. Iron, silica, carbonate of lime, carbonate of magnesia, and other substances may be introduced into rocks by this means.

Inflation (*Cycles*). *See* TYRES.

Influence Machine (*Elect.*) A general name for static electrical machines which make use of the principle of induction instead of friction. *See* HOLTZ, WIMSHURST, *and* VOSS MACHINES.

Infula, *pl.* **Infulæ** (*Cost.*) The pendent lappet or lappets hanging from a bishop's mitre and falling on the shoulders. Originally the term was applied to a form of mitre itself.

Ingate (*Foundry*). The gate (*q.v.*) by which fluid metal enters a mould.

Ingenhausz's Experiment (*Heat*). An experiment to compare the conductivities of different materials in the form of rods or bars of equal section and similar state of surface. The bars are coated with wax, and one end of each kept at a fixed temperature by means of boiling water or other convenient method. When a steady state is reached, the wax is melted to different lengths along the bars, and the conductivities are proportional to the squares of the lengths of the melted wax.

Ingot (*Met.*) A mass of metal which has been poured into a mould in order to give it a shape (usually that of a short rectangular bar) convenient for handling, transit, or storage.

Ingrain (*Dec.*) A class of wallpapers now very popular, made from dyed pulp, which gives the prevailing colour to the paper in contradistinction to ordinary wallpapers which are "grounded" or covered with distemper colour. Ingrains are often used quite plain, *i.e.* without pattern, but some are printed with a pattern in very light colours. The surface of most ingrains is absorbent, almost like blotting paper, and the usual method of applying plenty of paste and allowing it to soak cannot successfully be followed with them; as little moisture as possible must be used. In all cases lining or plain paper should be hung underneath, especially if old paper is left on the wall. Even when properly hung, ingrains are very apt to fade. The dyes employed are mostly fugitive. *See* PAPERHANGING, WALLPAPERS.

Initial Condensation (*Eng.*) Condensation of steam on first entering a cylinder. The loss of energy thus caused is largely prevented by keeping the cylinder hot by means of a STEAM JACKET (*q.v.*)

Initial Pressure (*Eng.*) The pressure at which steam first enters a steam engine cylinder, or the pressure of the gas in a gas engine cylinder at the instant after the explosion has occurred.

Injection (*Eng.*) Applied generally to the forcing of a small stream of fluid into a vessel, especially to the forcing of water into a boiler by means of an injector (*q.v.*), or into the condenser of an engine.

—— (*or* **Jet**) **Condenser** (*Eng.*) *See* CONDENSER.

Injector (*Eng.*) A piece of apparatus for forcing water into a boiler. A jet of steam mingles with a portion of the supply of feed water, and by its condensation causes a partial vacuum, into which the main portion of the feed water rushes with great velocity. The kinetic energy of the moving water is sufficient to force a steady stream of feed water into the boiler.

Inker (*Print.*) One of the rollers in a printing machine which apply ink to the type.

Inks. Writing ink is a mixture of ferrous and ferric gallates, to which gum has been added. It is made from nutgalls and ferrous sulphate (copperas), the gum serving to keep the gallates in suspension. The galls are sometimes replaced to a greater or less extent by use of logwood and indigo extract. Coloured inks are now usually made from coal tar dyes, *e.g.* eosin or magenta for red ink. SYMPATHETIC INKS are of various kinds. The writing may be done with a solution of cobalt nitrate, when it will be colourless till it is warmed; the heat will turn it blue. The writing may be done with silver

nitrate, when it will turn black on exposure to sunlight. The writing may be done with a solution of copperas, and afterwards made visible by washing with an extract of gallnuts. PRINTING INK is a mixture of boiled linseed oil and lampblack. Coloured inks are prepared by using a suitable pigment in place of the lampblack (vermilion, oxide of lead, lead chromate, Prussian blue, ultramarine, etc.) MARKING INK should contain silver nitrate, Indian ink, and gum.

Inlets for Fresh Air. *See under* SANITATION.

Inlier (*Geol.*) An exposure of rock which is completely surrounded by higher or newer rocks. It is a term which is usually restricted to sedimentary rocks occurring under the conditions named, but it is also applied to similar exposures of intrusive masses. It is a correlative to OUTLIER (*q.v.*)

Inoculation (*Hygiene*). A method of communicating a disease in a mild form by directly introducing infectious matter into the system. This renders man more or less insusceptible to such disease.

Inorganic Chemistry. A term long applied to the study of all the elements and their compounds, excepting those of carbon, which were supposed to be produced by or intimately connected with organic processes, *i.e.* processes carried on in or by the agency of animals and plants. The distinction between inorganic and organic chemistry was shown to be unreal and arbitrary when the synthesis of carbon compounds from their elements became general.

Inorganic Evolution (*Astron.*) An hypothesis which has many strong facts to support it, *viz.* that all the various kinds of matter, all the various so called chemical elements, may be built up in some way of the same fundamental substance.

Inorganic Ferments (*Chem.*) *See* ENZYMES.

Inosite *or* **Hexahydrohexaoxy Benzene** (*Chem.*), $C_6H_6(OH)_6$. A crystalline solid which exists in a dextro, a lævo, and an inactive form. It occurs in muscle (it is sometimes called muscle sugar), in the liver, and is largely distributed in the vegetable kingdom.

Insect Wax (*called also* **Chinese Wax**). Is secreted by the insect *Coccus ceriferus*. It is white, odourless, tasteless, and almost as hard as Carnauba wax (*q.v.*) It is used in Japan and China for making candles, sizing paper and cotton goods, but is not exported excepting in small quantities.

Insertion Joint (*Eng.*) A joint in pipes which is made watertight by the use of a ring or washer made of indiarubber or rubber alternating with layers of canvas.

Inset (*Print.*) A sheet, or the part of a sheet, which falls inside another sheet in sequence of pagination.

Inside (*Lace Manufac.*) A term that includes all the most delicate working parts of a lace machine, the principal being the "combs" and "points."

Inside Calipers. Calipers (*q.v.*) with the points turned outward, for measuring the internal diameter of a cavity.

Inside Crank (*Eng.*) A crank formed on the shaft so as to lie between the bearings; the most usual form.

Inside Cylinders (*Eng.*) Cylinders of a locomotive which are fixed inside the frame.

Inside Gouge (*Carp., etc.*) A PARING *or* SCRIBING GOUGE (*q.v.*)

Inside Lap (*Eng.*) *See* SLIDE VALVE.

Inside Lead (*Eng.*) *See* SLIDE VALVE.

Insolation (*Phys.*) Exposure to sunlight for the purpose of producing phosphorescence.

Inspection Chamber (*Sanitation*). A chamber at the junction of drains to allow of inspection. *See* DRAINS.

Installation. Machinery, plant, apparatus, etc., which is set up in a more or less permanent manner, *e.g.* machinery comprising engines, boilers, dynamos, switch boards, cables, wires, lamps, etc., for supplying electric light.

Instantaneous Centre. If two bodies are moving in any manner in a plane, their motion at any given instant can be fully represented as a rotation about a certain point, termed the INSTANTANEOUS or VIRTUAL CENTRE. This point is the intersection of two normals (the VIRTUAL RADII) drawn to the directions of the motion of the respective bodies.

Instantaneous Value (*Elect.*) The value of a current or electromotive force at any given instant. If the current (or E.M.F.) vary harmonically, then the instantaneous value (A) at time t is given by the equation

$$A = A_0 \sin pt,$$

where A_0 is the maximum value, and p a constant depending upon the frequency.

Instantaneous Vice (*Eng., etc.*) A vice in which the grip is obtained by some form of cam or rack. This can be disengaged at will, and a large movement of the jaws rapidly effected, the loss of time being much less than when the jaws are operated by a screw, as in the ordinary vice.

Instrumentation (*Music*). The art of orchestral writing.

Insulate, Insulation (*Elect.*) The separation of conductors from other conductors by means of non-conducting materials; also frequently used for the material itself. *See* INSULATING MATERIALS.

Insulating Materials *or* **Insulators** (*Elect.*) A perfect insulator is a substance which does not conduct electricity. No really perfect insulator has been discovered yet. In practical use the substances which approach the required conditions most nearly are those with very high resistance, *e.g.* glass, porcelain, ebonite, guttapercha, rubber, various resins and waxes, certain minerals (*e.g.* mica), silk, and various oils. Gases are almost complete insulators from the ordinary point of view of the practical electrician, though a gas may convey electricity freely at low pressures. The specific resistance (*q.v.*) of some important insulating materials is as follows:

Mica	$8{\cdot}4 \times 10^7$	megohms.
Glass	9×10^7	"
Guttapercha	$4{\cdot}5 \times 10^8$	"
Shellac	9×10^9	"
Ebonite	$2{\cdot}8 \times 10^{10}$	"
Paraffin wax	$3{\cdot}4 \times 10^{10}$	"

The above resistances are all given at ordinary temperatures.

Insulating Paint. A paint made of fossil gum, a pigment, and a vehicle, usually spirit or naphtha, intended for use in connection with electrical appliances, being unaffected by the current.

Insulating Resistance (*Elect.*) *See* INSULATING MATERIALS.

Insulator (*Elect.*) A support or coating composed of some INSULATING MATERIAL (*q.v.*); applied to a conductor in order to insulate it.

Intaglio (*Architect.*) A species of sculpture in which the subject is carved into the ground so as to form a hollow. *See* CAVO RELIEVO, BASSO RELIEVO, ALTO RELIEVO, *and* MEZZO RELIEVO.

—— (*Art*). (1) A figure engraved or cut into a substance so that the design is below the surface. (2) A gem with a figure or device cut in the foregoing manner, *e.g.* a seal. An *intaglio* or incised carving is the reverse of a CAMEO (*q.v.*)

Intensification (*Photo.*) Increasing the opacity of the image to actinic rays either by depositing additional silver from a solution of its salt or by the use of a metallic salt (very frequently mercury), followed by ammonia. Intensification does not add to the detail in the picture; it merely strengthens the image already formed.

Intensifiers (*Photo.*) Solutions used for INTENSIFICATION (*q.v.*) If mercuric chloride be employed, the negative is soaked in a solution of this until bleached, and, after well washing, blackened by means of either sodium sulphite, ammonia, or by the application of a ferrous oxalate developer.

Intensity of Light. The quantity of light which falls upon a unit area of the illuminated surface. Intensity is usually measured by comparison with an arbitrary standard, such as the light from a standard candle. *See also* ILLUMINATION.

Intensity of Magnetisation. A measure of magnetic strength based upon the idea of magnetic poles and action at a distance. It is numerically equal to magnetic moment divided by volume, and hence in the ideal case of a uniform bar having free poles wholly on the end surfaces it means the number of unit poles per unit area of end surface.

Interbedding (*Geol.*) A term used as a correlative to INTRUSIVE. It is thus applied equally to rocks of volcanic origin and to normal sediments, and conveys the idea of repeated alternations of conditions favourable to the deposition of beds of rock.

Interceptor (*Sanitation*). *See* DISCONNECTING TRAPS.

Intercepts (*Min.*) The lengths of the axes cut off by the crystal face or by the extension of the plane of that face. *See* SYSTEMS, CRYSTALLOGRAPHIC. The simplest example is the regular octahedron (of the cubic system), where the intercepts are all equal. The intercepts are thus, $1:1:1$. The face of the cube is parallel to two of the axes, but cuts the other at unity, hence the intercepts are $1:\infty:\infty$. The intercepts are always expressed as whole numbers, and these numbers are usually of low value, rarely more than ten. Thus, if the amount of one axis cut off by a face was half the unit length of that axis the intercepts are written $2:4:1$ instead of $1:2:\frac{1}{2}$.

Interchangeable Parts. In many modern machines it is customary for the makers to supply spare parts, which can be substituted for damaged or worn parts, without alteration or fitting. The production of strictly interchangeable parts is only possible when they are made very accurately to gauge, and depends very largely on the use of automatic machinery in the manufacture of the articles. Cycles, motor cars, seagoing machinery, and many machines required for export are some of the best examples of mechanism whose value is much increased by the interchangeability of parts.

Intercolumniation (*Architect.*) The space between two columns measured immediately above the bases, except in the case of the Greek Doric order, in which the intercolumniation is measured at the lowest part of the columns. *See* PYCNOSTYLE, SYSTYLE, EUSTYLE, DIASTYLE, ARÆOSTYLE, MONOTRIGLYPH, DITRIGLYPH, *and* TRITRIGLYPH.

Interdentils (*Architect.*) The space between two DENTILS (*q.v.*)

Interference (*Phys.*) A term chiefly used in connection with light waves, but applicable to wave motion generally, and really meaning that when two or more waves traverse the same space the net result is the algebraic sum of the separate disturbances. Hence two waves of equal frequency and amplitude will have a resultant zero when a phase difference of half a wave length (or any multiple of half a wave length) exists between them, and will, conversely, enhance each other's effect when the phase difference is a whole wave or any multiple of a whole wave.

Interference Colours (*Light*). Transparent laminæ of any material whatever exhibit colour if they are thin enough. This is due to the fact that some light is reflected from each surface; hence the part reflected from the second surface, having farther to go, is retarded with respect to the part reflected from the first surface, so that the two may strengthen or weaken each other according to the phase difference introduced. Such colours occur frequently in nature. Instances are soap bubbles, mother-of-pearl, very old glass articles, peacocks' feathers, and the plumage of many birds. These colours may be distinguished from absorption colours by the fact that the tint varies as the position of the observer changes.

Interference Fringes (*Light*). When two spherical waves diverge from closely adjacent point sources (or from two narrow parallel slits which are really rows of point sources), then in the space they mutually traverse there will be points at which they destroy each other by interference, and other points at which they reinforce each other. When a small portion of the wave front is received on a screen or the retina, the result is a series of bright or dark lines known as INTERFERENCE FRINGES. The distance between the lines varies with the wave length, hence monochromatic light is necessary for good definition, white light giving a series of superposed fringes of the various colours, and thus exhibiting rainbow tints. Such fringes can be produced in many ways—for instance, by Fresnel's bi-prism (*q.v.*)—and may often be observed by merely looking at a lamp filament through a pocket handkerchief or through the eyelashes.

Interlace (*Textile Manufac.*) This relates to the crossing of warp and weft, the order of the interlacing in a weave prescribing the structure of the cloth.

Intermat (*Textile Manufac.*) The term applied to the felting or shrinking of cloths, the fibres intermatting or felting together.

Intermediate Part. The term "intermediate" is applied in engineering to a wheel, shaft, cylinder, etc., which lies between and is connected to two similar parts.

Intermittent Downward Filtration. *See* FILTRATION, *and under* SANITATION.

Internal Characteristic (*Elect. Eng.*) A curve showing the relation between the current and the electromotive force in the armature of a dynamo. *See also* DYNAMO.

Internal Compensation (*Chem.*) *See* STEREOISOMERISM.

Internal Flue (*Eng.*) A flue running through a boiler so as to be surrounded entirely by water.

Internal Forces. Forces acting between different parts of the same body, *e.g.* stresses. *See* INTERNAL STRESS.

Internally Fired Boiler (*Eng.*) A boiler whose firebox or furnace is inside the boiler and surrounded by water.

Internal Mitre (*Build.*) The intersection of two mouldings forming an angle of less than 180°.

Internal Resistance (*Elect.*) The resistance which a current generator of any kind itself possesses, and which cannot be varied, as distinguished from the external resistance, which may have any value. The sum of the two makes up the total resistance of the circuit.

Internal Screw (*Eng.*) A screw cut on the inside surface of a hollow cylinder (*e.g.* a nut). Also called a female thread.

Internal Stress (*Eng.*) Strictly, all stresses are internal in their nature; but the term is especially applied to stresses in a piece of material which are not due to the load or other applied forces, but to contraction or some similar fault due to bad design or construction.

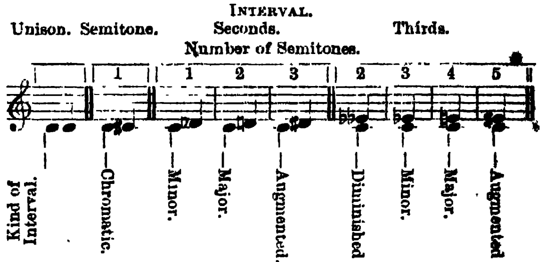
Internal Work (*Phys.*) Whenever a substance alters its volume in consequence of a heat change in it, some work must be done by or done against external pressure, and therefore it is convenient to distinguish between the heat actually given out or absorbed by the substance and corresponding to internal work, and the portion equivalent to the external work done. For instance, about 537 heat units are required to change unit mass of water at 100° to steam at 100°, and of these about 40 are expended against atmospheric pressure, the remainder being actually required for the change of state, or internal work.

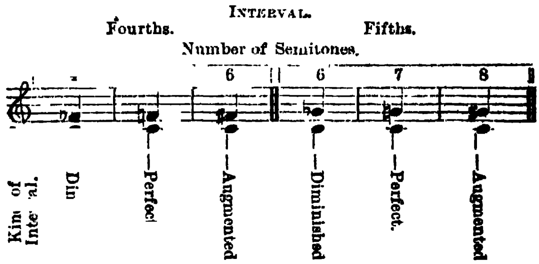
Interrupted Cadence (*Music*). *See* CADENCE.

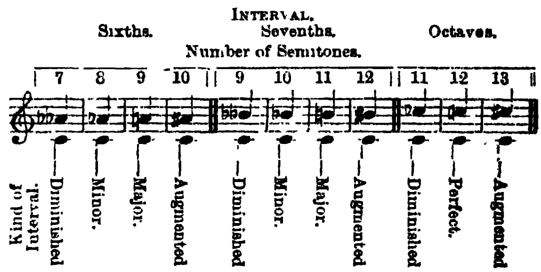
Intersection Theory (*Textile Manufac.*) The theory of cloth construction determined by the number of intersections or interlacings between warp and weft yarns and their relative diameters.

Inter-Tie (*Carp. and Join.*) The intermediate horizontal timber forming the tie in a trussed partition.

Interval (*Music*). The difference in pitch between any two sounds; scientifically, the ratio between the frequencies of two notes. In music, intervals are reckoned from the lower sound upwards, including both notes, and classed according to the number of alphabetical letters included. Thus C to G is a fifth, as it includes the letters c, d, e, f, g. Intervals exceeding an octave are called compound intervals, and with the exception of the ninth, eleventh, and thirteenth are for harmonic purposes reduced to simple intervals by subtracting seven and treated as that simple interval; *e.g.* a twelfth is treated as a fifth, or a fifteenth (double octave) as an octave or eighth. Intervals are subdivided into different classes according to the number of semitones contained: seconds, thirds, sixths, and sevenths are called major and minor; fourths, fifths, and octaves, perfect. Intervals a semitone less than perfect or less than minor are called diminished, and those a semitone greater than perfect or major are called augmented. The following table gives the intervals within an octave and the number of semitones contained in each. Note that in each case the interval, as stated above, is counted according to the alphabetical letters contained, not according to the number of semitones contained; *e.g.* C to G♮ is a fifth, whilst C to F♯ is a fourth, although in each case the number of semitones contained is six.







When an interval is turned upside down it is said to be "inverted." The inversion may easily be found by subtracting the interval from 9; thus:

 is a major sixth,  (the inversion) is a minor third. By inversion perfect intervals remain perfect, major become minor, minor become major, augmented become diminished, diminished become augmented.

Intrados. *See* ARCH.

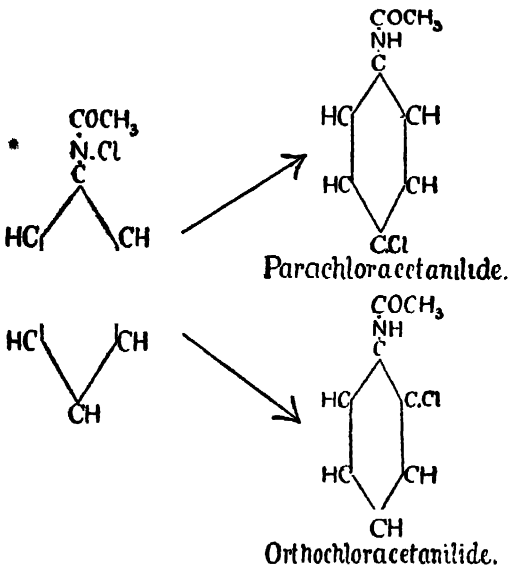
Intramercurial Planets (*Astron.*) Planets which may possibly revolve round the sun in orbits inside that of Mercury.

Intramolecular Change. The name given to a kind of reaction in which the atoms which compose the molecule of certain compounds undergo a rearrangement and produce a new compound. This kind of change can be brought about in many ways,

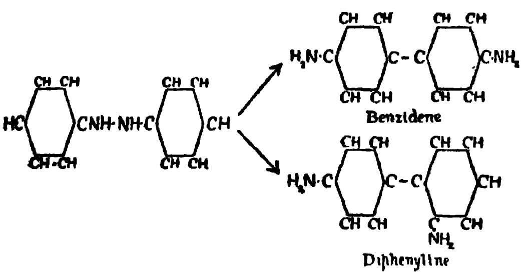
as the following examples show: (1) Ammonium cyanate is transformed into urea on evaporating its aqueous solution on the water bath:

$$N \vdots C . ONH_4 = CO\langle^{NH_2}_{NH_2}.$$

(2) Hydrazobenzene is transformed by acids, even in the cold, into benzidine and a small quantity of diphenylene:



(3) Phenylacetyl nitrogen chloride is transformed, on standing in glacial acetic acid solution, into parachloracetanilide and a small quantity of orthochloracetanilide:



(4) Nitrous acid changes oleic acid into elaidic acid (*q.v.*) It also changes maleic acid into fumaric acid:

$$\begin{array}{ccc} COOH.C.H & & COOH.C.H \\ \| & = & \| \\ COOH.C.H & & H.C.COOH \end{array}$$

Some of the alkaloids undergo intramolecular rearrangement to a remarkable extent: thus cinchonine forms the isomeric alkaloids cinchonicine, cinchonidine, allocinchonine.

Intrusive Rocks (*Geol.*) Eruptive rocks which have made their way, while in a fluid state, upward and outward from deep seated sources (presumedly in connection with volcanic foci), and which have consolidated somewhere below the surface. The great majority of intrusive rocks *replace* their own volume of the rock they invade, *i.e.* they do not *displace* it. Intrusive rocks may conveniently be distinguished in accordance with the position below the surface at which consolidation took place, as PLUTONIC, in the case of the deeper seated rocks, and TRAPPEAN for the remainder.

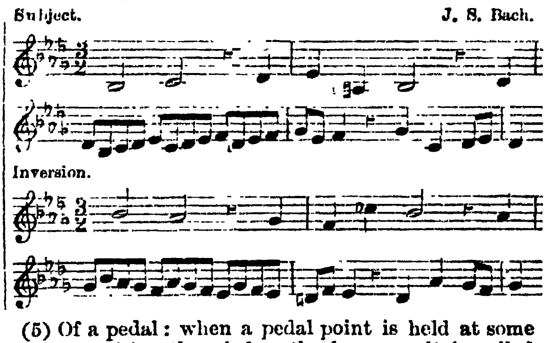
Inulin (*Chem.*), $(C_6H_{10}O_5)_n$. A white crystalline solid which occurs in many plants, *e.g.* in dahlia tubers, in chicory, etc. It is coloured yellow by iodine. On hydrolysis with water containing a trace of sulphuric acid, it yields pure lævulose.

Invected (*Her.*) A partition line formed by semicircular indentations, the converse of engrailed. *See under* HERALDRY.

Inverse Square Law (*Phys.*) Most physical phenomena (electric and magnetic forces, various forms of radiation, etc.) are observed to decrease in amount as we recede from the source or point from which the effect proceeds; if by doubling the distance the effect fall to one quarter of its previous value, the phenomenon is said to follow the INVERSE SQUARE LAW. Thus, if the amount of force (*e.g.* electric or magnetic attraction) at a given point be f, and the distance of the point from the source or origin of the force be r, the law is expressed by the equation $f=\frac{k}{r^2}$, k being a constant.

Inversion (*Chem.*) A name given to the change which occurs when cane sugar is treated with dilute acids. Cane sugar is dextrorotatory. After warming with very dilute sulphuric acid it is changed to a mixture of equal quantities of dextrose and lævulose, of which the latter is more strongly lævorotatory than the former is dextrorotatory. Hence the product is lævorotatory. This change in the direction of rotation gave the name Inversion to the process.

—— (*Music*). (1) Of Intervals (*see* INTERVAL). (2) Of a chord: when any note other than the Root is in the Bass or lowest part, a chord is said to be inverted. (3) Of Counterpoint: when the lower part is placed above the upper in Double Counterpoint, or *vice versâ*. (4) Of a Fugue subject: when the subject is given in contrary motion, thus:



(5) Of a pedal: when a pedal point is held at some other position than below the harmony it is called an inverted pedal.

Inversion of Images (*Elect.*) An application of the mathematical theory of inversion to the solution of problems on electrostatics. When any one problem is solved, the solution of another may be deduced by a purely geometrical process.

Inversion, Thermoelectric (*Elect.*) If one junction of a thermoelectric couple be kept at 0° C. and the other varied in temperature, there will usually be some point at which the E.M.F. becomes zero and then reverses its direction. For instance, with iron and copper the temperature of inversion would be 550° C. More generally, for any two metals

forming a thermo-couple, there is usually some temperature, called the neutral temperature, such that there is no E.M.F. in the circuit when the mean temperature of the junctions is equal to the neutral temperature. When the mean value is less than this, the E.M.F. is in one direction, and in the opposite direction when the mean value is greater. For copper and iron the neutral temperature is 275° C.

Invertase *or* **Invertin** (*Chem.*) A widespread enzyme. It occurs in brewers' yeast; in some moulds and bacteria; in the plants yielding cane sugar; in the liver and intestines of man. The process of extraction from yeast is complex and long. In outline it is as follows: Yeast is treated with strong alcohol, and the *residue* with chloroform water; the latter is filtered into absolute alcohol, and the precipitate dried *in vacuo* over sulphuric acid. The product still contains ash, which can only be removed by an elaborate process. It is a light white powder, and its importance lies in its power of inverting cane sugar. *See* INVERSION. Traces of acid promote its action, while traces of alkali retard its action. Its optimum temperature is about 50° C.

Inverted Arc (*Elect. Eng.*) An arc light having a conical reflector fixed beneath it, so as to throw the light upward. Used in a room with a flat ceiling, it produces very uniform illumination, free from shadows, and is suitable therefore for workshops, drawing offices, and many other purposes.

Inverted Arch (*Build.*) An arch built (near the footings) upside down to distribute the weight of piers, etc., over a greater area.

Inverted Commas. Commas placed thus " " to denote that the matter is quoted; also to denote the title of a book, etc.

Invert Sugar (*Chem.*) The mixture of dextrose and lævulose obtained on inversion of cane sugar. *See* INVERSION.

Involucre (*Botany*). The investment of overlapping scales or bracts on the underside of the capitulum or inflorescence of the *Compositæ*. A similar, but less crowded, involucre occurs in the *Umbelliferæ*, at the base of a main branch of the umbel.

Involute. If a cord wrapped round a curved surface be unwound (the unwound portion being kept tight), its free end will describe a plane curve, termed the INVOLUTE of the first curve; the original curve is termed the EVOLUTE of the curve generated by the end of the cord. If the cord be unwound from a circle, the curve obtained is termed the INVOLUTE OF THE CIRCLE.

Involute Teeth. Wheel teeth whose curves are formed by the involutes (*q.v.*) of a circle. In such teeth, both the root and point of the teeth form parts of one continuous curve. By reason of this property the distance between the axles of two gearing wheels with involute teeth can be varied without interfering with the smoothness of action of the teeth. Such wheels are used in rolling mills, etc., where the distance between the axles is apt to vary somewhat. No other form of wheel teeth will allow of this variation.

Iodates (*Chem.*) Salts of iodic acid. Sodium iodate occurs naturally along with sodium nitrate. *See under* IODINE. Potassium iodate, KIO_3, is obtained by the action of caustic potash solution on iodine, $3I_2 + 6KOH = 5KI + KIO_3 + 3H_2O$. As the iodate is much less soluble than the iodide, it can be separated by repeated crystallisation. The salt may also be obtained by heating either iodine or potassium iodide with potassium chlorate. On heating, it loses oxygen and some iodine, forming potassium iodide and some oxide. It combines with iodic acid to form acid salts. Silver iodate, $AgIO_3$, is obtained by double decomposition between silver nitrate and potassium iodate, $AgNO_3 + KIO_3 = AgIO_3 + KNO_3$. Stas used this salt in one of his numerous determinations of the atomic weight of silver. On heating, it loses oxygen and some iodine, leaving a residue of silver iodide and some silver.

Iodic Acid (*Chem.*), HIO_3. A heavy white crystalline solid, soluble in water, insoluble in alcohol. Kept at 200°, it loses water and forms the anhydride iodine pentoxide. It behaves as a strong oxidising agent; *e.g.* it oxidises hydriodic acid to water and iodine, $HIO_3 + 5HI = 3H_2O + 3I_2$. Used as a test for morphine, which liberates iodine from it. It is prepared by heating iodine with strong nitric acid, evaporating to dryness, heating the residue for some time at 200° to expel all nitric acid, and crystallising from water.

Iodine, I. (*Chem.*) *Atomic weight*, 127. Dark grey lustrous solid; melts at 114°; boils at 184°. The vapour is blue when pure, reddish violet when mixed with air; below 700° the molecule is diatomic; at 1700°, monatomic. Sp. gr. of iodine = 5. It is slightly soluble in water, forming brownish solution; very soluble in potassium iodide solution, giving a red solution; very soluble in carbon disulphide and chloroform, giving a violet solution. Strong solutions of iodine in carbon disulphide do not transmit the visible and ultra violet rays of the spectrum, but do transmit rays of greater wave length than these (so called "heat rays"). It unites with many elements forming iodides; *e.g.* hydrogen (*see* HYDRIODIC ACID), mercury (*q.v.*), iron (*q.v.*) With caustic soda or potash it forms potassium iodide and iodate, $3I_2 + 6KOH = 5KI + KIO_3 + 3H_2O$. With ammonia it forms nitrogen iodide (*q.v.*) Strong nitric acid oxidises it to iodic acid (*q.v.*) With starch paste it gives a deep blue colour: this reaction supplies a common test for the presence of iodine. Iodine occurs in sea water and in sea plants and animals, hence it is present in sponges and in cod liver oil; in crude Chile saltpetre; combined with certain metals, *e.g.* silver; in certain rather rare ores; in some mineral springs, *e.g.* one at Woodhall Spa near Lincoln is famous for the free iodine it contains; in the thyroid gland in man. The world's production of iodine is practically under the control of a syndicate which owns nearly all the South American and a great part of the Scotch iodine manufacture. The French iodine makers are bound by the syndicate only to produce for home consumption. Most iodine is extracted from Chili saltpetre, $NaNO_3$, which contains sodium iodate, $NaIO_3$, as impurity. On crystallising the solution of the crude nitrate, sodium nitrate separates out, while the iodate remains in solution. From the solution sodium hydrogen sulphite precipitates the iodine, $2NaIO_3 + 5NaHSO_3 = 3NaHSO_4 + 2Na_2SO_4 + 2H_2O + I_2$. Iodine is also obtained from seaweed in Scotland and in France. The weed (deep-sea weed) is either carefully burned or is simply extracted with water to dissolve out the soluble salts. In the former case the ash is extracted with water. The solution in both cases is concentrated, when the less soluble salts (sulphates, etc.) separate out. The mother liquor, which contains the iodides, is distilled with manganese dioxide and

sulphuric acid in quantity just insufficient to liberate all the iodine. All iodides treated in this way give up their iodine, $2KI + MnO_2 + 3H_2SO_4 = 2KHSO_4 + MnSO_4 + 2H_2O + I_2$. Iodine is purified by subliming. Pure iodine is obtained by dissolving sublimed iodine in potassium iodide solution, precipitating it by water, distilling in steam, drying over calcium nitrate, and redistilling over barium oxide.

Iodine Absorption *or* **Iodine Value** (*Chem.*) Unsaturated fatty acids have the property of uniting directly with iodine: so also have their glycerides (fats). The amount of iodine which combines with 100 parts of the fatty acid or fat is called the iodine absorption or iodine value of the fat. The acid or fat is weighed and dissolved in chloroform and an excess of Hübl's reagent added, the amount added being known. Hübl's reagent is made by dissolving 25 grams of iodine in 500 cc. of 95 per cent. alcohol and 30 grams of mercuric chloride in a like amount of the same alcohol, and mixing the two solutions. The excess of iodine is found by titration with a standard solution of sodium thiosulphate: 100 parts of oleic acid require 90 parts of iodine, and 100 parts of olein require 86·2 parts; thus if the only unsaturated acid or fat present were oleic acid or olein, its amount is readily found. The iodine value of a fat can always be found; but if the fat is a mixture of glycerides of unsaturated fatty acids, the amount of each constituent can only be calculated in simple cases. The process is useful in estimating the amount of olein in butter, as olein is the only unsaturated fat present in butter.

Iodine Pentoxide (*Chem.*), I_2O_5. A white solid obtained by heating iodic acid at 200°; at 300° it decomposes into iodine and oxygen. It dissolves in water, forming iodic acid.

Iodobenzene, C_6H_5I (*Phenyliodide*). A colourless liquid: boils at 188°. Obtained by heating benzene, iodine, and iodic acid together at 200°. The iodic acid converts the hydriodic acid liberated by the action of the iodine into iodine again:

$$5C_6H_6 + 4I + HIO_3 = 5C_6H_5I + 3H_2O.$$

Also it is prepared by diazotising aniline with hydrochloric acid and sodium nitrite (*see* DIAZO COMPOUNDS), and adding strong potassium iodide solution and warming. Iodobenzene unites with dry chlorine in chloroform solution, forming a dichloride—a yellow crystalline solid, $C_6H_5ICl_2$, in which iodine is *trivalent*. The iodobenzene dichloride, when treated with caustic soda solution, is converted into IODOSOBENZENE,

$$C_6H_5ICl_2 + 2NaOH = C_6H_5IO + 2KCl + H_2O,$$

which explodes about 200°, and liberates iodine from a solution of potassium iodide acidified with acetic acid. It also acts as a base, forming salts which may be regarded as derived from $C_6H_5I\langle^{OH}_{OH}$, *e.g.* iodosobenzene acetate, $C_6H_5I\langle^{OOCCH_3}_{OOCCH_3}$. When iodosobenzene is heated alone, or heated in steam, or preferably oxidised with hypochlorous acid, iodoxybenzene, $C_6H_5IO_2$, is obtained: it forms colourless crystals which explode at about 230°. When a mixture of iodosobenzene and iodoxybenzene is shaken with moist silver oxide, a solution of DIPHENYLIODONIUM HYDROXIDE is obtained:

$$C_6H_5IO + C_6H_5IO_2 + AgOH = (C_6H_5)_2IOH + AgIO_3.$$

This substance behaves like a strong base, and forms salts with acids. Thus the chloride, bromide, iodide, nitrate, carbonate, etc., are known. The iodide $(C_6H_5)_2I.I$ is polymeric with iodobenzene. The iodonium compounds may be regarded as derivatives of the unknown compound IH_2OH, which is called iodonium.

Iodoform (*Chem.*), CHI_3. Shining yellow scales; melts at 120°; characteristic odour; insoluble in water; soluble in alcohol, ether, chloroform; used as an antiseptic and disinfectant for sores and wounds, its action being probably due to liberation of iodine, as the unchanged substance does not appear to be an antiseptic. Hydriodic acid converts it into methylene iodide, $CHI_3 + HI = CH_2I_2 + I_2$. The zinc-copper couple reduces it to acetylene, as does also finely divided silver. It can be distilled in steam. It is obtained by warming alcohol with a solution of sodium carbonate to about 80°, and gradually adding iodine; when cool, the clear liquid is separated from the precipitated iodoform, and as it contains sodium iodide, more alcohol and carbonate are added and chlorine passed in to liberate the iodine, when a further quantity of iodoform is obtained. It is also obtained electrolytically: the positive pole of a battery dips into a solution of sodium carbonate, potassium iodide, and alcohol, contained in a porous cell, and the negative pole into a solution of caustic soda, which surrounds the porous cell. Many other substances besides alcohol give iodoform when warmed with sodium carbonate solution and iodine, *e.g.* the higher homologues of alcohol (normal alcohols), also aldehyde and its homologues, acetone, etc. The production of iodoform from alcohol serves as a delicate test for the latter, of course only in the absence of the other substances named.

Iodol *or* **Tetraiodopyrrole** (*Chem.*) $\begin{array}{l}CI=CI\\ \ \vert\qquad\ \ \rangle NH.\\ CI=CI\end{array}$ Brownish yellow prisms; melts at 140°, with decomposition; no smell; insoluble in water; soluble in hot alcohol; soluble in ether; prepared by the action of iodine on pyrrole (*q.v.*); preferably in presence of an alkali. It is used as an antiseptic in place of iodoform, as it has no smell; its action is the same.

Iodonium Compounds (*Chem.*) *See* IODOBENZENE.

Iodosobenzene (*Chem.*) *See* IODOBENZENE.

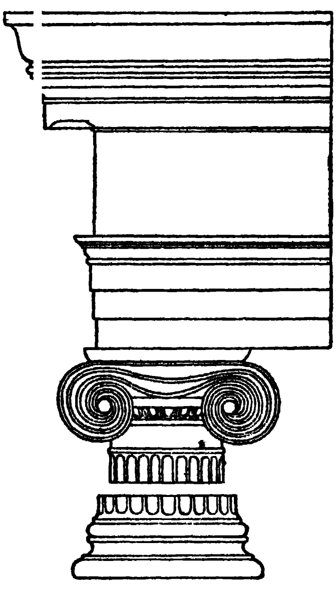
Iolite (*Min.*) Silicate of aluminium, magnesium, and iron, $H_2O.4(Mg.FeO).4Al_2O_3.10SiO_2$. Silica $= 49·4$, alumina $= 33·9$, magnesia $= 8·8$, ferrous oxide $=$ 7·9 per cent. Orthorhombic, in blue crystals, often dichroic (whence the synonym DICHROITE). More easily fused than Quartz, softer than Sapphire. It is used as a gem under the name Saphir d'eau. From Norway, France, Ireland, Bavaria, etc.

Ion (*Elect.*) A term introduced by Faraday to denote the current carriers in electrolysis. Ions include ANIONS and CATIONS, which appear at the anode and cathode respectively. The term has since come to signify a portion of ordinary matter associated with a definite electric charge, either positive or negative; for instance, a solution of common salt in water probably consists partly of unaltered molecules and partly of free sodium and chlorine atoms, carrying positive and negative charges respectively. These latter are the ions, and their number increases with the dilution. Their presence confers conductivity on the solution, and if the dissolved substance does not ionise, it will not conduct. Every

monad atom in electrolysis appears to carry exactly the same charge, and every dyad atom twice that charge, and so on. Whilst in this state the ordinary chemical properties of the substance are in abeyance, only becoming apparent when the charge is removed. *See also* IONISATION; IONS, VELOCITY OF; *and* IONS, MIGRATION OF.

Ionian (*Music*). *See* MODES.

Ionic Order (*Architect.*) This order was adopted by the Greeks in Ionia during the fifth century B.C. It is less sturdy, less severe, and treated with greater freedom than the Doric. For description *see* ARCHITECTURE, ORDERS OF.



IONIC ORDER.

Ionic Velocity (*Elect.*) *See* IONS, VELOCITY OF.

Ionisation (*Elect.*) The dissociation of a compound body into ions—that is, into atoms or molecular groups carrying definite electric charges. The phenomena are most striking in the case of electrolysis, and the great value of water as a solvent for electrolytes appears to depend upon its power of facilitating ionisation. Although gases are among the best of non-conductors at ordinary pressures, they may be ionised, and will then conduct more or less. This may be done in various ways, amongst others by ultra-violet light, by Röntgen rays, or by the radiations from radium and other radio-active substances. *See also* ION.

Ionisation Coefficient (*Elect.*) The fraction of the total number of dissolved molecules which exist in the condition of ions. Thus if N be the total number of molecules of the dissolved substance present in the solution, and n the number dissociated or broken up into ions, the ionisation coefficient is $\frac{n}{N}$. This quantity is also termed the DISSOCIATION COEFFICIENT.

Ionone (*Chem.*) *See* TERPENES.

Ions, Migration of (*Elect.*) During electrolysis the strength of a solution does not remain uniform, but becomes greater near one electrode than at the other. This is still the case when all allowance is made for the influence of secondary reactions, and the observed fact first suggested the idea that different ions travel with different velocities under the same potential difference. *See also* ION, IONISATION, *etc.*

——, Velocity of (*Elect.*) The charged ions of an electrolyte during electrolysis move in opposite directions towards the electrodes with velocities which depend upon the nature of the ion and upon the difference of potential per unit length. Hydrogen ions move the fastest, at the rate of about ·0035 centimetres per second, under a P.D. of 1 volt per centimetre. These velocities may be calculated by measuring the change of concentration at the electrodes and also the electric conductivity. In some cases the motion may be made visible, and the direct measurements thus obtained agree very well with the calculated values.

Ipecacuanha. The roots of this Brazilian plant, *Uragoga ipecacuanha* (order, *Rubiaceæ*), furnish the ringed Ipecacuanha, while the striated variety is the produce of a closely allied genus.

Ipomœa (*Botany*). A genus of the order *Convolvulaceæ*, consisting of climbing plants chiefly. The sweet potato is the tuberous root of *I. batatas*, and the swollen roots of *I. purga* yield JALAP.

Iridium (*Min.*) This rare metal occurs native in cubic crystals, or more often in silvery grains. It also occurs in the alloy IRIDOSMINE with osmium. Its hardness is 6—7, and its specific gravity about 22·7. Found chiefly in the Urals.

——, Ir. (*Chem.*) Atomic weight, 193. A shining white metal; next to osmium, the heaviest known element; melts at over 2,000°—that is, higher than platinum, and the oxyhydrogen flame only melts it with difficulty. In fine state of division it is dissolved by aqua regia, but not after it has been melted. It occurs naturally along with platinum. After the platinum has been removed from the ore by aqua regia there remains a shining scaly residue which consists of an alloy known as OSMIRIDIUM. This alloy consists chiefly of iridium and osmium, with small amounts of the other platinum metals and iron or copper. This alloy is heated with common salt in a stream of moist chlorine, when most of the osmium volatilises, and the iridium and other metals form soluble double chlorides with the salt. The solution of these is treated while boiling with sulphuretted hydrogen; the other metals are precipitated as sulphides first, and the gas is stopped as soon as the orange yellow iridium sulphide begins to appear. The liquid is filtered, evaporated, and the double chloride $6NaCl . IrCl_4 24H_2O$ recrystallised. This is converted into the ammonium salt, which is less soluble, and on heating yields finely divided iridium. It can be made coherent by heating to whiteness and pressing. *Uses:* The standard metre is an alloy of 10 per cent. iridium and 90 per cent. platinum. Vessels of platinum with 25 to 30 per cent. of iridium are not attacked by aqua regia. It is also used in making iridium pointed pens. Its salts resemble those of platinum to some extent, and are unimportant.

Iridosmine (*Min.*) *See* IRIDIUM (*Min.*)

Iris (*Botany*). A genus of the order *Iridaceæ* known as "Flags." The violet scented rhizomes of *Iris florentina* (Orris root) are used in perfumery.

—— (*Zool.*) The coloured portion of the eye, formed by a continuation of the choroid coat to form a circular curtain to the front of the eye. The opening in the centre (the pupil) becomes smaller or larger under the varying intensity of light.

Iron, Fe. Atomic weight, 56. Pure iron is a soft white metal not possessing any of the useful properties of steel, wrought iron, or cast iron; it melts about 1600°; that is, higher than any of the useful forms of iron. When pure iron is heated to near its

melting point and allowed to cool slowly, a remarkable and sudden decrease in the rate of cooling occurs at a temperature of about 860°. Except for this, the rate of cooling is very regular. This retardation of cooling can only be due to a liberation of heat in the iron itself, and the only feasible explanation of such behaviour is that the iron at this point changes from one state to another. The phenomenon of heat liberation is called recalescence, and the form of iron above the point of recalescence is called β-ferrite; that below, α-ferrite. These two forms of iron play an important part in the hardening of steel. Above the recalescent point iron is not magnetic; below this point iron is magnetic. Pure iron is easily oxidised in air, the change occurring rapidly at high temperatures, very slowly at ordinary temperatures, unless the iron is in a very fine state of division, when it is spontaneously inflammable (pyrophoric). In dry air, ferric oxide, Fe_2O_3, is formed on complete oxidation; but in moist air, hydrated ferric oxide is formed, $Fe_2O_3xH_2O$, where the limit of x is 3. Pure iron is readily attacked by acids, forming ferrous salts. The action of very strong nitric acid is peculiar. This acid produces a superficial change, probably oxidising the surface to Fe_3O_4. Iron which has been plunged into very strong nitric acid is not attacked by dilute nitric acid, nor does it precipitate copper from solutions of copper salts. In this state iron is said to be "passive." If the surface of such iron be removed, as by filing, it loses its passivity, and again dissolves in dilute nitric acid and precipitates copper. Other oxidising agents besides nitric acid, *e.g.* chromic acid, can produce passivity. Pure iron can be obtained by reducing the pure ferric oxide in hydrogen, when the metal is obtained pyrophoric at low temperatures, and non-pyrophoric at high temperatures; also by electrolysis of a solution of ferrous sulphate. It is doubtful if iron occurs free on earth except in the form of meteorites. It occurs in combination in the hæmoglobin of the blood and in the green parts of plants. The chief ores of iron are, magnetite, Fe_3O_4; red hæmatite, Fe_2O_3; brown hæmatite, Fe_2O_3, combined with more or less water; spathic iron ore, $FeCO_3$; clay ironstone, which is $FeCO_3$ associated with clay; and black band ironstone, which is $FeCO_3$ associated with carbonaceous matter. Iron also occurs combined with sulphur as iron pyrites, FeS_2, which is not used as an ore of iron, but is largely used in the manufacture of sulphuric acid. The following is a brief description of the extraction of iron from its ores: it applies to clay ironstone or black band ironstone, and would be modified for other ores. The operation is carried out in a blast furnace. *See* FURNACES. Before the ore is put in the furnace it is calcined; that is, heated to drive off carbon dioxide and water, and to render it more porous. During this process the iron is changed from the form of carbonate to that of the oxides Fe_3O_4 and Fe_2O_3. Along with the ore there is also put into the furnace coke and limestone, the former serving as fuel and the latter as a flux, which will combine with the silica and aluminium oxide of the ore to form a fusible double silicate of calcium and aluminium which constitutes the slag. The chemical composition of the ore and the character of the product required determine the proportions of coke and limestone to be added to the ore, and all three are weighed out and introduced into the furnace at the top by means of the cup and cone arrangement. A blast of air heated to from 300 to 600° by being drawn through chambers heated to redness by the waste gases of the furnace is blown into the furnace under a pressure of 4 to 5 lb. per square inch through a number of openings in the furnace a little above the place where the slag is drawn off. The changes which occur in the furnace are somewhat as follows: The oxygen of the air forms carbon monoxide with the excess of carbon contained in the coke, and the carbon monoxide reduces the oxide of iron to the metal, being converted in the process to carbon dioxide. This is the predominant change in the higher regions of the furnace. Lower down, where the temperature is higher, the reducing action of carbon itself plays a part, reducing oxide of iron to the metal, and forming probably carbon dioxide. But at high temperatures iron can take up oxygen from both oxides of carbon, reproducing iron oxide. Finally, carbon dioxide can combine with carbon to form carbon monoxide. Until the hottest part of the furnace is reached the result produced is the difference between the opposing reactions just described, the reducing reactions preponderating. Coke and clay both contain small quantities of sodium and potassium, and these metals, in the form of carbonate, are converted by nitrogen in presence of carbon at a high temperature into potassium cyanide, which is a powerful reducing agent. This compound is produced in the furnace, and reduces the remaining portions of iron oxide to the metal. The iron which now melts dissolves carbon, silicon, manganese, phosphorus, and sulphur, the last two being present in traces only, and sinks to the bottom of the furnace, whence it is withdrawn from time to time. The lime of the limestone and the aluminium oxide of the clay unite with the silica forming the slag, which melts and floats above the iron and is withdrawn at much more frequent intervals than the iron. The product of the blast furnace is called PIG IRON or CAST IRON. Various grades of pig iron are produced, depending on the ratio of ore to fuel, and therefore on the temperature. Grey cast iron is produced when the ratio (called the burden of the furnace) is low, white cast iron when the burden is high. The chief differences between grey and white cast iron are: Grey cast iron contains most of its carbon free; it is softer than white cast iron. On melting, it passes at once to the fluid state, while white cast iron becomes pasty, and is never so fluid; also grey cast iron melts at a higher temperature. Grey pig iron is used for castings; white in making steel. Varieties of cast iron containing much manganese are called spiegeleisen or ferromanganese, and are used in steel making. WROUGHT IRON is the purest form of useful iron, and is usually made in this country from grey pig iron by a process known as the puddling process. This process is carried out in a reverberatory furnace (*see* FURNACES) having a cast iron bottom, covered with a slag technically called "bulldog" (it is a mixture of ferrous silicate and ferric oxide, obtained by roasting the slag—"tap cinder"—of a previous operation), and the scale beaten out of the wrought iron when it is hammered under the steam hammer. The pig iron is placed in the furnace with slag from a previous operation. Part of the impurities are burned away during the melting. When the iron has melted, it becomes covered with a layer of slag, which prevents further oxidation; it is well stirred with iron bars by the puddler, and the carbon is removed from the iron by union with ferric oxide from the furnace bed. The metal is now made purer, and melts at a higher temperature, so that it is only pasty at this stage of the process. It is accordingly made into "blooms," and removed from the furnace to the steam hammer,

where the slag is beaten out of it; after this it is rolled. A better quality wrought iron is produced by cutting this product into bars, heating them, and again rolling them; and this process may be repeated. *See* FAGOTING. STEEL is intermediate, as to the amount of carbon it contains, between cast iron and wrought iron, so that it can be made from a very pure iron by addition of carbon, or from an iron rich in carbon by removing some of this element. The cementation process is an example of the first method. In this process bars of wrought iron are heated in contact with carbon and out of contact with air to about the melting point of copper. The extent of carburisation that takes place depends on the time the carbon is left in contact with the iron; if the time is short, the iron is only case hardened. HARVEYISED STEEL is produced by case hardening, and then suddenly cooling the metal by ice cold water, directed as a spray on the carburised surface. When the iron has been exposed the required time to the action of the carbon, the bars are melted to obtain a homogeneous product, and then cast. Very high quality steel is made in this way. The carbon probably enters the iron partly by a process of diffusion between the two solids and partly through the agency of carbon monoxide. In other processes for steel making a combination of the two methods mentioned above is adopted, cast iron being deprived of all, or nearly all, its carbon, and then the requisite amount of carbon added to it, usually in the form of high carbon pig iron containing manganese or silicon (spiegeleisen or ferrosilicon). OPEN HEARTH PROCESS: A regenerative furnace (*see* FURNACES) is employed. If the iron to be used is nearly free from phosphorus, the hearth is of silica; if phosphorus is present to an appreciable amount, it is of calcined dolomite (*q.v.*) In the SIEMENS-MARTIN PROCESS the charge consists of pig iron, scrap iron and steel, and iron oxide ores. The ores are added gradually after the melting of the pig and scrap. Some of the impurities are oxidised during the melting, especially manganese and silicon; after melting, most of the carbon is removed by the iron oxide ores as carbon monoxide. The metal now contains too little carbon, and the requisite amount of carbon is added in the form of spiegeleisen and ferrosilicon (cast iron rich in silicon). Low carbon steels are usually made in this way. The Siemens process differs from the above in that ore is not used. BESSEMER PROCESS: In this process a special apparatus known as the Bessemer converter is used. The converter is an iron vessel with a lining of gannister (*q.v.*); the bottom is perforated with holes which open into a box supplied with a blast of air when the converter is working, of sufficient pressure to keep the molten charge from entering the holes. The blast is supplied to the box by a pipe which communicates with one of the two trunnions which support the converter, this trunnion being hollow, while the other is solid. The trunnions allow of the converter being turned through an angle of 180° for filling and emptying, and through the hollow trunnion the blast is supplied to the converter. Melted pig iron is brought into the converter while on its side, the blast is turned on, and the converter brought into the vertical position. Silicon and manganese are first oxidised by the air blast, then the carbon, the latter stage being marked by issue of flame from the mouth of the converter. This flame is due to carbon monoxide; and when it "drops" the blast is turned off as the oxidation of carbon is at an end. The metal now contains too little carbon, and the proper quantity of spiegeleisen is added to the converter. The process is now ended, and the charge is poured into ladles and cast. Converters with gannister linings will not remove phosphorus from pig iron; so that pig iron containing more than a trace of phosphorus cannot be used for steel making in such converters. Thomas and Gilchrist introduced a lining of calcined magnesian limestone in place of gannister in the converter for the manufacture of steel from pig iron containing phosphorus. Their process is called the basic Bessemer process, because the strong non-volatile bases calcium oxide and magnesium oxide combine with the acid oxide of phosphorus to form phosphates. To prevent the lining being rapidly used up in this way, lime is added to the charge, and forms, with the phosphoric oxide, a slag of basic calcium phosphate which is a valuable manure. *Varieties of Useful Iron:* Wrought iron contains 99·6 to 99·8 per cent. of iron; it has the highest melting point of all the useful forms of iron; it is soft and fibrous; strongly magnetic, but not retentive of magnetisation; cannot be hardened or tempered; is easily welded; it is malleable and ductile. Steel may contain from about 0·2 per cent. of carbon to 1·5 per cent. Low carbon steels are called MILD STEEL, and approach wrought iron in properties. It melts below wrought iron; is harder and less ductile; more difficultly magnetisable, but once magnetised it is retentive of its magnetism, so that steel is used in making permanent magnets, while wrought iron is used in making electromagnets. The carbon in steel confers upon it the unique property of being hardened and tempered. If steel be heated above the point of recalescence of pure iron, and then suddenly cooled, it becomes hard, high carbon steels becoming so hard that they will cut glass (glass hard). The degree of hardness can be reduced to any desired extent, between certain limits, by again heating the steel to a temperature dependent on the degree of hardness required, but always lower than in hardening, and again cooling. This process is called TEMPERING. Steel which has been heated to a high temperature and slowly cooled is said to be annealed. The chemical and microscopical examination (the latter a branch of the science of metallography) of steel have shown it to consist of various substances, which confer on it its characteristic properties. The more important of these substances are: (1) α- and β-FERRITE. The former is the same as pure iron; the latter is a harder and non-magnetic modification of iron present in steel when it has been heated above the recalescent point of pure iron and suddenly cooled, the carbon in the steel hindering its transformation into α-ferrite. (2) CEMENTITE, a name given to the carbide of iron Fe_3C, which is present in high carbon steel. (3) MARTENSITE, which occurs in the hardest steel and is a solution of iron carbide in iron. (4) PERLITE, which is a mixture of α-ferrite and cementite, containing 0·8 per cent. of carbon. Steel heated above the recalescent point of pure iron may be regarded as a solution of cementite in β-ferrite. The changes that occur as the temperature falls will depend on the rate of cooling and the amount of cementite present. With sufficient cementite and rapid cooling we shall have the hardest steel, consisting of β-ferrite and martensite. If the cooling is slow the iron will revert to α-ferrite; the soft modification and cementite will separate out, and soft steel will result. Between these extremes it is clear many gradations can exist. In the tempering of

hardened steel the metal is heated to such a temperature that changes in the proportions of the constituents mentioned occur in the sense that β-ferrite changes to α-ferrite, and cementite separates out from solution. The working of steel also alters its structure markedly. Several other elements besides carbon have an important influence on the properties of steel. Thus manganese above a certain percentage renders steel non-magnetic; it also retards or prevents the conversion of β- to α-ferrite, and thus makes a hard steel. Chromium in steel confers remarkable properties upon it. "The use of chromium alloyed with iron in making projectiles . . . is now general; they contain from 1·2 to 1·5 per cent. of chromium, and will hold together even when they strike steel plates at a velocity of 2,000 ft. per second" (ROBERTS-AUSTEN). Nickel in steel confers great hardness upon it: Harveyised nickel steel is employed in making armour plates. Cast iron has already been mentioned: it may contain from 2·5 to 4 per cent. of carbon; white cast iron even more. W. H. H.

Iron (*Min.*) This element occurs native in Greenland in some quantity, and very sparingly in Auvergne, Brazil, Ireland, etc. Iron of meteoric origin has been found in many parts of the world. Native iron is cubic, is malleable and ductile, and exhibits all the properties of the artificially reduced metal. Meteoric iron usually contains admixture of other metals.

Iron Cement (*Eng.*) A mixture of iron filings or borings with a very small amount of sal-ammoniac (ammonium chloride). This mixture rusts and hardens into a solid mass, which fills up joints in iron piping, etc., and makes them watertight. *See* RUST JOINT.
